Encyclopædia Britannica.

Vol. IV.—(BOK–CAN).

Total number of Articles, 727.

PRINCIPAL CONTENTS.

BOLIVIA. Keith Johnston, Fellow of the Geographical Society.
BOMBAY. Hon. W. W. Hunter, LL.D., Director of Statistics to the Government of India.
BOOK. E. Fairfax Taylor.
BOOKBINDING. James Paton, Corporation Galleries, Glasgow.
BOOKKEEPING. F. Hayne Carter, Chartered Accountant, Edinburgh.
BORNEO. H. A. Webster.
BOSTON. G. E. Ellis, D.D., Boston.
BOTANY. Dr J. Hutton Balfour, F.R.S., Late Keeper of Botanic Garden, Edinburgh.
BOTTICELLI. Prof. Sidney Colvin, University of Cambridge.
BOWLS. H. F. Wilkinson.
BRACHIOPODA. Thos. Davidson, LL.D., F.R.S.
BRAHMANISM. Julius Eggeling, Ph.D., Professor of Sanskrit and Comparative Philology, University of Edin.
BRAKE. A. B. W. Kennedy, Professor of Engineering, University College, London.
BRASS. James Paton.
BRAZIL. Keith Johnston.
BREEDS. Francis Darwin, M.B., F.R.S.
BREHON LAW. Sir Samuel Ferguson, LL.D., Q.C., Deputy Keeper of Public Records, Dublin
BRETSCHNEIDER. Rev. F. Crombie, D.D., Professor of Divinity, etc., University of St Andrews.
BREWING. S. A. Wyllie.
BRICK. A B Macdowall.
BRIDGES. Fleeming Jenkin, F.R.S., Professor of Engineering, University of Edinburgh.
BRITANNIA. A. W. K. Miller, British Museum.
BRONCHITIS. Dr J. O. Affleck, Royal College of Physicians, Edinburgh.
BRONZE. A. B. Macdowall and A. Stuart Murray.
BROUGHAM. Henry Reeve, C.B.
BROWNING, MRS. George Barnett Smith.
BUCCANEERS. Thomas Shaw, LL.B., Advocate.
BUCKINGHAM, DUKE OF. Prof. S. Rawson Gardiner, Author of "The History of England, 1624–28."
BUCKLE, HENRY. Robert Flint, D.D., Professor of Divinity, University of Edinburgh.
BUDDHISM. T. W. Rhys Davids, LL.D.
BUFFON. H. Alleyne Nicholson, M.D., Professor of Natural History, University of Aberdeen
BUILDING. Wyatt Papworth.
BUILDING SOCIETIES. Edward W. Brabrook.
BUNSEN. G. von Bunsen, Berlin.
BURKE. John Morley, M.P., Editor of the "Men of Letters" Series.
BURNS. John Nichol, LL.D., Professor of English Language, University of Glasgow.
BUTLER, BISHOP. Prof. Robert Adamson, Owens College, Manchester.
BUTLER, SAMUEL. George Saintsbury, M.A.
BUTTERFLIES. John Gibson, Industrial Museum, Edinburgh.
BUTTON. J. J. Lake.
BYRON. W. Minto, M.A., Professor of Logic, University of Aberdeen.
BYZANTINE HISTORIANS. R. Garnett, LL.D.
CABLE. Thos Morley, Fellow of Institute of Naval Architects.
CACTUS. Thos. Moore, late Curator, Chelsea Botanic Garden.
CÆDMON. Thomas Arnold, M.A.
CÆSAR. Oscar Browning, Fellow of King's College, Cambridge.
CALCULATING MACHINES. P. R. S. Lang, M.A., Professor of Mathematics, University of St Andrews.
CALCUTTA. Hon. W. W. Hunter, LL.D.
CALEDONIA. James Macdonald, LL.D.
CALENDAR. W. S. B. Woolhouse, Author of "Measures and Weights of all Nations."
CALICO PRINTING. J. Paton.
CALIFORNIA. Prof. Josiah D. Whitney.
CALVIN. W. Lindsay Alexander, D.D., one of the Bible Revisers.
CAMBODIA. Col. Yule, C.B.
CAMISARDS. W. C. Smith, LL.B., Advocate.
CAMOENS. F. W. Cosens.
CANAANITES. Rev. Canon Cheyne, M.A., Oriel Professor of Exegesis, University of Oxford.
CANADA. Prof. Daniel Wilson, Toronto.
CANAL. David Stevenson, C.E.
CANARY ISLANDS. J. Yate Johnson.
CANNIBALISM. E. B. Tylor, LL.D., Author of "Primitive Culture."
CANOE. John MacGregor, Author of "The Rob Roy on the Jordan."

ENCYCLOPÆDIA BRITANNICA.

BOKHARA

BOKHARA, Bukhara, or Bukharia, a country and khanate of Central Asia, in Turkistan or Independent Tartary, lying between lat. 37° and 41° N., and long. 62° and 69° E. Its extent has been greatly diminished during recent years both on the N. and S.,—in the former direction by the conquests of Russia, and in the latter by the encroachments of Afghanistan. A considerable stretch of country, including the important towns of Balkh, Andkhoi, and Meimene, was at various times regarded as an integral part of the khanate; but at present the River Oxus forms for the most part its southern boundary. To the W. it is conterminous with the khanate of Khiva and the desert of Kharezm, which now form part of the Russian empire; and on the E. it stretches to the khanates of Kunduz and Khokand. Its area is estimated at 100,000 square miles. A large part of the western half of the land consists of a desolate steppe of argillaceous clay, broken by hills of slate and bare granite rocks; the eastern parts are occupied by offshoots of the Hindu-Koh and Tien-shan ranges, and the Pamir steppe. The cultivated land is confined almost entirely to the immediate neighbourhood of the rivers, of which the most important are the Amu or Oxus, the Zer-Affshan, and the Karshee. The Amu (Jihon or Kohik), which only belongs to the khanate in the middle part of its course, flows from S.E. to N.W., and varies in width from 300 to upwards of 800 yards. The Zer-Affshan, inferior to the Amu in the volume of its waters, and superior to it in the populousness and cultivation of its banks, rises in the high lands east of Samarkand, and, passing north of that city and of Bokhara, forms a lake in the province of Karakul about 25 miles in length. Its whole course is about 340 miles. The Karshee rises in the mountains to the S.E. of Samarkand, and passes through Shehr-Sebz and Karshee, below which it is lost in the desert.

There are no gold mines in Bokhara, but that metal is found among the sands of the Oxus in greater abundance, perhaps, than in any of the other rivers which flow from the Hindu-Koh. The climate of Bokhara is exposed to great variations. In summer the heat is often very great, and in winter the cold is proportionally severe. The frosts commence about the end of November, and continue till towards the end of April. The Amu is generally frozen over for some weeks in winter so as to be passable for caravans. In the desert the heat in summer exceeds 100° Fahr. Thunder-storms and earthquakes are not unfrequent, especially in the spring; and there are sometimes violent tornadoes, generally blowing from the N.W.

Inhabitants.

The population of Bokhara, composed of Tadjiks, Arabs, Uzbeks, Turkomans, Persians, Mervi, and Jews, may be estimated at between 1,000,000 and 2,000,000. Meyendorff estimates it at 2,478,000, Khanikoff at from 2,000,000 to 2,500,000, Burnes at less than 1,000,000, and Wolff at 1,200,000. The Tadjiks are the aborigines of the country, and are said to have come from the west, and settled on the banks of the Zer-Affshan at a time when the country was uninhabited, and a jungle of reeds covered the place where the town of Bokhara now stands. Except in the town of Bokhara, where they constitute the majority of the population, there are few Tadjiks now in the khanate. They are mostly engaged in commerce, are peaceful or even cowardly in their disposition, and are characterized by avarice, faithlessness, and deceit. They are usually tall, with handsome and regular features, fair complexion, and black eyes and hair. The number of Arabs, though not considerable, exceeds that of the Tadjiks. They are the descendants of the followers of Kutribe, who conquered the country about the beginning of the 8th century, and compelled the inhabitants to adopt the Mahometan faith. Their numbers are stated at 60,000, and they inhabit the northern part of the khanate, especially the neighbourhood of Vardanzi and Vafkend. Like their ancestors they still continue to lead a wandering life, their chief occupation being the tending of their flocks. Their moral qualities seem to be of a higher character than those of the Tadjiks. The Uzbeks, the last people that conquered this country, are the most numerous, and are at present the dominant race. They are divided into a number of tribes, of which the principal is that of Manghit. To it the reigning dynasty belongs. Some of the Uzbeks are nomadic in their habits, others are engaged in agriculture or live in towns. They are more bold and straightforward in their manners than the Tadjiks, but have unfortunately degenerated from contact with that race. There are a considerable number of Persians in Bokhara, most of whom have been brought as slaves from their native country. They are readily distinguished by the regularity of their features, and their bushy black

hair. Large numbers of them rise by their intelligence and faithfulness to occupy important situations. Although outwardly conforming to the faith and manners of the country, they cordially hate the native races, and are ready to hail with joy any political revolution which might shake the power of the Uzbeks. The Jews, though long established in the country, form but a very inconsiderable part of its inhabitants. They are chiefly to be found in Bokhara and some of the larger towns, where they have separate quarters assigned to them. Their privileges are very restricted The Mervi, who number about 40,000, are the people who were transplanted from the city of Merv on its destruction about 1810 by Emir Said Khan. The Turkoman and Kirghiz part of the population is wholly nomadic, and is chiefly to be found in the regions south of the Oxus.

Vegetable products.

The orchards in the neighbourhood of the larger towns are numerous and highly cultivated. They produce grapes, figs, peaches, pomegranates, apricots, plums, apples, pears, and quinces. The cultivation of cotton, tobacco, and lucerne is extensively carried on, as is also that of the mulberry, beet, cabbage, carrots, radishes, onions, cucumbers, pease, beans, lentils, melons, and pumpkins. The soil being of a saline nature requires to be cultivated with some care, so that it is found to be much more profitably laid out in gardens than in fields; indeed, the returns from the former exceed by sevenfold the returns from the same quantity of the latter. Wheat, rice, barley, millet, and joar (*Sorghum vulgare*) are the principal kinds of grain grown. The last-named is one of the most useful productions of the khanate, and as it is cheap and nutritious, it forms the chief subsistence of the poor.

Animals.

The horses of Bokhara are numerous, but are more remarkable for strength than for beauty. Asses are also very plentiful, and are large and sturdy. The camels, by means of which the entire traffic of Bokhara is carried on, are reared chiefly by the wandering tribes, particularly the Turkomans. They have a sleek coat as fine as that of a horse, and shed their hair in summer; from the hair a fine waterproof cloth of close and rather heavy texture is manufactured. The goats are about the common size, of a dark colour, and yield a shawl-wool inferior only to that of Kashmir. The bulls and cows are miserably small, and in very wretched condition. The rearing of sheep is much attended to, particularly by the Arabs. There is a peculiar breed, said to thrive only in the district of Karakul, which produces a jet-black curly fleece that is much valued. The wild animals are few. Tigers of a diminutive species are found in the valley of the Oxus; wild hogs, herds of deer, antelopes, and the wild ass roam on the plains; and foxes, wolves, jackals, and ounces are found in some parts. All kinds of game are scarce. The scorpion is common. The most valuable insect is the silkworm, which is reared in all parts of the khanate where there is water—every rivulet being lined with the mulberry.

Commerce.

Bokhara owes its importance to its central position. Lying on the route between Europe and the richest part of Asia, it is the seat of a considerable transit trade. The Government has established custom-houses, built caravanserais, and constructed cisterns along such caravan roads as are insufficiently supplied with water, but otherwise does nothing to encourage traffic; and the roads are generally in a wretched condition. Religious fanaticism formerly rendered it impossible for any except Mahometan merchants to trade with safety in the country; but since 1868 all at least who are in any way under the protection of Russia have full freedom to import or transport their wares throughout the country. Bokhara carries on an extensive trade with Russia by means of caravans, which travel by the following routes, viz.,—by the route of Khiva to the shores of and across the Caspian from and to Astrakhan; by the route to and from Orenburg by land in sixty days, through Orghenj in Khiva; to and from Troidska in Tobolsk, by the route east of the Sea of Aral, in forty-nine days; and to and from Petropavlosk (Kizil Djar) in ninety days. From 5000 to 6000 camels are annually employed in this trade. Bokhara exports to Russia, besides cotton, which is the principal item, dried fruits, rice, raw and dyed silks, indigo, silk sashes, turquoises, shawls, and furs. It imports muslins, calicoes, chintzes, some silk stuffs, broad-cloth, brocades, hides, iron, and other metals. The trade with Khiva employs only from 1000 to 1500 camels, and consists chiefly in exporting to Bokhara Russian goods, of which there is always an available surplus in the markets of Khiva. Three, and occasionally four, caravans arrive annually from Meshid in Persia, bringing cotton and silk stuffs, calicoes, chintzes, muslins, carpets, shawls, turquoises and opium, and receiving in return lamb-skins, cotton, rice, &c. From Herat and Kashmir is imported a considerable quantity of shawls and Indian produce and English manufactures from Kabul. A brisk traffic is also carried on with Khokand, Tashkand, Kashgar, and Yarkand. The central points of commerce are Bokhara and Karshee; and trade is principally conducted at the marts and fairs that are held in various parts of the country. Almost the only manufactures carried on in Bokhara are those of cotton goods, silks, carpets, leather, hardware, and jewellery. There is one manufactory of cast-iron articles. Swords and knives are fabricated at Hissar and Karshee, and excellent paper of raw silk at Bokhara.

Education.

Bokhara has for ages been reckoned the centre of Mussulman erudition; and if we look at the number of its schools and the state of education among its people, we cannot but admit that, in that respect, it ranks first among the states of Central Asia. About one-fourth of the population is said to be able to read and write. The primary schools are numerous in the capital, as well as in the other cities, and even in villages. The course in these schools extends over about seven years. Those wishing to continue their studies then enter the *medresses*, or seminaries, in which they pursue a higher course of studies, chiefly theological, under one or two professors who have acquired the right to give lectures. Each establishment has a fixed number of students, according to the extent of the building. Fifteen or even twenty years are reckoned insufficient to go through a complete course in these institutions. The people are, however, very superstitious, believing in witchcraft, omens, spirits, and the evil eye.

Government.

The Government is a hereditary despotism, the khan having the power of life and death over his subjects. The civil administration is in the hands of the clergy, and is founded on the Koran and the commentaries upon it. The military and civil dignitaries are divided into three grades. The troops of the khan are estimated at about 40,000 men, but of these not more than one-third are completely armed. The languages in use are the Persian and Turkoman; the latter is spoken by the Uzbeks, and the wandering tribes south of the Oxus.

History.

Bokhara was known to the ancients under the name of Sogdiana. It was too far removed to the east ever to be brought under the dominion of Rome, but it has shared deeply in all the various and bloody revolutions of Asia. It is mentioned by the earliest historical writers of Persia; and the foundation of the capital is ascribed to Efrasiab, the great Persian hero. About the year 856, Yacub-bin-Leis is said to have been invested with the government of that province by the caliph. About twenty years later it was conquered by Ismael, the first sovereign of the Sassanean dynasty, whose successors held it until the renowned Malek Shah, third of the Seljuk dynasty

of Persia, passed the Oxus about the end of the 11th century, and subdued the whole country watered by that river and the Jaxartes. In 1216 Bokhara was again subdued by the celebrated Mahomet Shah Kharezm, who enjoyed his conquest but a short time ere it was wrested from him by Genghis Khan in 1220. The country was wasted by the fury of this savage conqueror, but recovered something of its former prosperity under Octai Khan, his son, whose disposition was humane and benevolent. His posterity kept possession till about 1400, when Timur bore down everything before him. His descendants ruled in the country until about 1500, when it was overrun by the Usbek Tatars, under Ebulkhier Khan, the founder of the Sheibani dynasty, with which the history of Bokhara properly commences. The most remarkable representative of this family was Abdullah Khan, who greatly extended the limits of his kingdom by the conquest of Badakhshan, Herat, and Meshed, and greatly increased its prosperity by the public works which he authorized. Before the close of the century, however, the dynasty was extinct, and Bokhara was at once desolated by a Kirghiz invasion and distracted by a disputed succession. At length, in 1598, Baki Mehemet Khan, of the Astrakhan branch of the Timur family, mounted the throne, and thus introduced the dynasty of the Ashtarkhanides. The principal event of his reign was the defeat he inflicted on Shah Abbas of Persia in the neighbourhood of Balkh. His brother Veli Mehemet, who succeeded Baki in 1605, soon alienated his subjects, and was supplanted by his nephew Imamkuli. After a highly prosperous reign this prince resigned in favour of his brother, Nezr Mehemet, under whom the country was greatly troubled by the rebellion of his sons, who continued to quarrel with each other after their father's death. Meanwhile the district of Khiva, previously subject to Bokhara, was made an independent khanate by Abdulgazi Bahadur Khan; and in the reign of Subhankuli, who ascended the throne in 1680, the political power of Bokhara was still further lessened, though it continued to enjoy the unbounded respect of the Sunnite Mahometans. Subhankuli died in 1702 at the age of 80, and a war of succession broke out between his two sons, who were supported by the rivalry of two Usbek tribes. After five years the contest terminated in favour of Obeidullah, who was little better than a puppet in the hands of Rehim Bi Atalik, his vizier. The invasion of Nadir Shah came to complete the degradation of the land; and in 1740 the feeble king Ebulfeiz paid homage to the conqueror, and was soon after murdered and supplanted by his vizier. The time of the Ashtarkhanides had been for the most part a time of dissolution and decay; fanaticism and imbecility went hand in hand. On its fall the throne was seized by the Manghit family in the person of Mir Maasum, who pretended to the most extravagant sanctity, and proved by his military career that he had no small amount of ability. He turned his attention to the encroachments of the Afghans, and in 1781 reconquered the greater part of what had been lost to the south of the Oxus. Dying in 1802 he was succeeded by Saïd, who in bigotry and fanaticism was a true son of his father. In 1826 Nasrullah Bahuder mounted the throne, and began with the murder of his brother a reign of continued oppression and cruelty. Meanwhile Bokhara became an object of rivalry to Russia and England, and envoys were sent by both nations to cultivate the favour of the emir, who treated the Russians with arrogance and the English with contempt. The Russian armies were gradually advancing, and at last they appeared in Khokand; but the new emir, Mozaffer-eddin, instead of attempting to expiate the insults of his predecessor, sent a letter to General Chernayeff summoning him to evacuate the country, and threatening to raise all the faithful against him. In 1866 the Russians invaded the territory of Bokhara proper, and a decisive battle was fought on 20th May at Irdjar on the left bank of the Jaxartes. The Bokharians were defeated; but after a period of reluctant peace they forced the emir to renew the war. In 1868 the Russians entered Samarkand (May 14) and the emir was constrained to submit to the terms of the conqueror. Bokhara, though still nominally independent, is in reality subject to Russia, which must ere long absorb it completely.

Hitherto European intercourse with Bokhara has been very slight, and few travellers have personally visited it. The Brothers Polo were there in the time of Borak Khan (1264–1274) and Anthony Jenkinson in 1558–9, Cladisheff in 1740, Meyendorff and Nagri in 1820, Burnes in 1832, Wood in 1838, Khanikoff and Lehmann in 1841–2, Stoddart and Conolly in 1842, Danilevsky in 1842–3, and Vambery in 1863.

See Khanikoff's *Bokhara*, translated by De Bode (1845); Vambery, *Travels in Central Asia* (1864), *Sketches of Central Asia* (1868), and *History of Bokhara* (1873); Fedchenko's "Sketch of the Zarafshan Valley" in *Journ. R. Geogr. Soc.* for 1870; Hellwald, *Die Russen in Central Asien* (1873).

BOKHARA, or BUKHARA, the capital of the above khanate, is situated six or seven miles from the left bank of the Zer-Affshan, in 39° 48′ N. lat. and 64° 26′ E. long. It is about eight miles in circumference, has a triangular shape, and is surrounded by an earthen wall about 20 feet high, which is pierced by eleven gates. It is divided into two main portions known as the Deruni Shehr and Beruni Shehr, or the inner and outer city, and these are subdivided into several districts. Of the former splendours of "Bokhara the Noble" the remains are comparatively few, and the general appearance of the city is very disappointing. Vambery describes it as one of the dirtiest and most unhealthy places in all Asia. The streets are extremely narrow, and the houses, flat-roofed and built of sun-dried bricks on frameworks of wood, are small and only one story in height. The bazaars are very numerous, and each trade has its own. There are about thirty small caravanserais throughout the city, which serve partly as store-rooms and partly as inns. The largest building in Bokhara is the Mosque of Kelan, which was originally built by Timur, and was restored by Abdullah Khan. It occupies a square of 300 feet, and is surmounted by a dome 100 feet high. There the khan comes to pay his devotions on Fridays in the midst of his subjects. Among the other mosques, which are fabulously said by the inhabitants to number 365, the most important are the Mesdjidi Mogak, a subterranean building of uncertain origin, and the Divanbeghi, which dates from 1629. In the neighbourhood of the latter is an open square, with a reservoir in the middle, which forms one of the favourite lounges of the people of Bokhara. On the opposite side rises the ark or palace of the khan, a gloomy building on an elevated site. Bokhara has long been regarded as the intellectual centre of Central Asia, and possesses a large number of educational establishments. There is hardly a street without its school, and the number of colleges or *medresses*, set down too at 365 by the inhabitants, is really about 80. Of these the handsomest is Abdullah's, which was built in 1372, and contains about 100 cells. Others date from 1426, 1529, and 1582; and one was founded by the Empress Catherine of Russia. The water supply of Bokhara is very defective, and the canals that convey it from the river are left in such an extreme state of filthiness, as readily to account for the prevalence of many forms of disease. The population was estimated by Meyendorff at about 70,000, and in this he was supported by Moorcroft and Khanikoff. Burnes raised the number to 150,000, and Wolff to 180,000; but it is now stated by Vambery at no more than 30,000.

BOLBEC, a town of France, capital of a canton in the department of Lower Seine, 18 miles E.N.E. from Havre on the railway to Paris, which here passes over high embankments and a viaduct. It was burned almost to the ground in 1765, but is now a flourishing brick-built manufacturing town, well supplied with water-power by the Bolbec stream. The principal manufactures are cotton goods, woollen cloth, and leather; there are also linen factories and dye-works. Population in 1872, 9019.

BOLEYN, ANNE, or, as the name is variously spelled, Bullen, Bouleyn, Boullan, or Boulain, queen of England, and second wife of Henry VIII., was the daughter of Sir Thomas Boleyn, a distinguished politician, and Lady Elizabeth Howard, daughter of the earl of Surrey, afterwards duke of Norfolk. Considerable obscurity rests over the date of her birth, which has been variously stated as 1501 and 1507; perhaps the earlier date is the more probable. She received a very careful education, and in 1514 became maid-in-waiting to Mary Tudor, then the affianced bride of Louis XII. of France. She crossed to France in Mary's train, but did not return with her, having entered the service of Queen Claude, where she was celebrated for her beauty, talents, and accomplishments. The period of her return to England has been matter of dispute; some, following Herbert and others, would make the date about 1522, others 1527. It may be assumed with some confidence that she returned about the earlier date. About this time occurred her love affair with Percy, afterwards earl of Nort umberland, which was broken off by Wolsey, acting apparently under the directions of the jealous king. Henry seems already to have begun to direct his affections towards the fair Boleyn, who was then one of the maids of honour attached to his consort, Katherine of Aragon. He advanced her family, but is said to have been repulsed by her when he made an offer of his love. In 1527, after some absence from the court, she seems to have returned, and Henry's attentions to her became more marked than before. His passion soon opened his eyes more clearly to the sin of his marriage with his deceased brother's wife, and the subject of the divorce began to be seriously discussed. Towards 1530 Anne Boleyn was accustomed to keep state almost as queen; in 1532 she was raised to the peerage with the title of marchioness of Pembroke, and accompanied Henry in his visit to France. On January 25, 1533, according to a contemporary report, her ambition was crowned by a private marriage with Henry. On the 12th of April she was openly proclaimed queen, and the marriage was again solemnized; and on the 8th of May the king's previous marriage was declared to have been null and void. The coronation took place on the 19th of May, and on the 7th September, a princess, the famous Elizabeth, was born.

Little is known of the new queen's married life. She to some extent favoured the Reformers, and countenanced the translation of the Bible. In January 1536 she gave birth to a prince, still-born. It is said that this mishap was occasioned by her suddenly becoming aware of Henry's attentions to Lady Jane Seymour. However this may be, Henry's superstitious fears seem to have been roused by the want of a male heir, and his fancy for Anne Boleyn had been replaced by a new passion. In April 1536 a committee sat privately to inquire into certain accusations of adultery against the queen. A special commission was called on the 24th April, and orders were issued for the arrest of the Viscount Rochford, the queen's brother, Sir Henry Norris, Sir Wm. Brereton, Sir Francis Weston, and Mark Smeton, all her alleged paramours. At the same time writs were issued for a new parliament. On the 2d May the queen was arrested and summoned before the privy council. Smeton, Norris, and Weston were afterwards examined, and of these Smeton confessed, though it was said under torture. Norris is thought to have made some admission, which, however, he afterwards withdrew. All three were committed to the Tower, to an apartment in which the queen was also consigned. Henry wrote to her, holding out hopes of pardon if she would be open and honest. Her reply, however, strongly affirms her innocence, and its general tone goes far in her favour. (The authenticity of the queen's letter has been doubted, though on slight grounds, by Mr Froude.) The juries of Middlesex and Kent, before whom proceedings opened, found true writs charging the queen with adultery, committed with the above-named Rochford, Brereton, Weston, Norris, and Smeton, and all with conspiring against the king's life. On the 12th May, Brereton, Norris, Weston, and Smeton were tried at Westminster, found guilty, and condemned. On the 15th Anne Boleyn and her brother were tried before twenty-seven peers, found guilty, and sentenced. On the 17th Smeton was hanged, the others beheaded. Their remarks on the scaffold were general, and can be interpreted fairly in neither way. Before the queen's execution she is said to have confessed to Cranmer some previous impediment which rendered her marriage with the king null and void, but what the confession was is absolutely unknown. On the 19th May she suffered death on Tower Green. On the next day Henry was married to Jane Seymour. Over the whole episode of Anne Boleyn's trial and execution the deepest obscurity rests. All traces of the evidence have vanished, and the conflicting judgments of historians, it must be confessed, seem generally to be determined by the bias of the individual writer.

See *State Trials*, where Burnet and the older writers are quoted; Strickland, *Lives of the Queens of England*; Miss Binger, *Life of A. Boleyn*; and the histories of Lingard and Froude.

BOLI, a town of Asiatic Turkey, in Anatolia, situated about 85 miles N.W. of Angora, on the Philios Chai, to the south of the Boli Dagh, in 31° 40′ E. long. and 40° 45′ N. lat. It is the capital of a sandjak and the seat of a governor, and contains a ruined castle and numerous mosques and baths, nowise remarkable in their structure. Cotton and leather are manufactured; the country around is fertile, and in the neighbourhood is a forest, from which Constantinople is largely supplied with wood. There are warm springs in the vicinity. Boli is built not far from what is regarded by Leake as the ruins of Hadrianopolis, where many marble fragments with Greek inscriptions are still found. The population is conjecturally stated at 10,000.

BOLINGBROKE, HENRY ST JOHN, VISCOUNT, was born in October 1678. His father, Sir Henry St John, the descendant of an old and noble family, was a noted rake of the Restoration period, who continued to live his life of pleasure and indolence for upwards of ninety years. Of his mother little is known, save that she was a daughter of the earl of Warwick. The education of her son was entrusted to the care of his grandmother, Lady St John, who was a professed Puritan and of a pious disposition. His tutor was a Dr Burgess, then renowned for his wit not less than for his piety, whose instructions in divinity seem to have been somewhat distasteful, if we are to accept the pupil's account of the dreary studies he was compelled to engage in. At an early age he was sent to Eton, where he appears to have been a school-fellow, though hardly a rival, of Walpole, and then proceeded to Christ Church, Oxford. The life he led at the university was typical of his later career. His brilliant talents and unusually retentive memory enabled him to amass an immense amount of information—more, indeed, than he was given credit for; while at the same time he began to

acquire an equally high reputation for dissipation and licentiousness. He was the Rochester of the period, with more than Rochester's abilities. He sought and gained the fame of a modern Alcibiades or Petronius. Amidst all his excesses, however, he maintained a real interest in literature. He was intimate with Dryden, and prefixed a laudatory poem to the first edition of the translation of Virgil. The verses did not hold out high promise of poetic power; and his later efforts in the same direction did little for his literary reputation. His most considerable production, *Almahide, an Ode*, is a miserable tawdry affair; the light ode to the equally light *Clara* is very much better, and has some vivacity and sparkle. He seems to have been conscious of his want of poetic genius, for his verse remains are not numerous.

For two years, from 1698 to 1700, he resided on the Continent, and during that time acquired the thorough mastery of the French language which was afterwards of so much service to him. On his return his friends, in the hope of withdrawing him to some extent from his loose mode of life, negotiated a marriage with the wealthy daughter of Sir Henry Winchescomb, a baronet of Berkshire. Marriage, however, effected little or no change in St John, and, though his wife never formally separated from him, and always retained a true affection for her husband, their married life was unhappy and divided. In February of the year following he entered Parliament as member for Wootton-Basset.

The Tory party, from a combination of circumstances, were then all-powerful in the House of Commons. The Partition Treaty, a measure for which, indeed, little can be said, had not met with popular favour, while William's large grants to foreigners, together with the general coldness and repulsiveness of his manners, had rendered him most unpopular. A perfect storm of discontent had arisen, and the Tories were nearly bewildered with the power which had been suddenly placed in their hands. Harley, perhaps, at that time, from his moderation, the most influential man of the party, led the House as speaker. St John enrolled himself among the Tories with the utmost enthusiasm, and from the first displayed such brilliant powers as placed him at once in the front rank, and gave him an almost unique position. His youth and high birth, his handsome and commanding presence, and his agreeable address, no doubt contributed largely to his rapid elevation; but what above all secured for him an unequalled success was his wonderful eloquence. The powers he unexpectedly evinced as an orator and debater were unrivalled then, and, if we are to take contemporary reports as our authority, had never been equalled, and have seldom, if ever, been surpassed. Not a fragment of his many speeches has come down to us; but from the criticisms of those who heard him speak, and from his published writings, some idea of their general quality may be gathered. The most prominent characteristics seem to have been copiousness and readiness, extreme fluency, and spontaneity, combined with a brilliant felicity of phrase, the right expression seeming to spring up naturally along with the thought to be expressed. His sentences are mostly massive and balanced, yet never heavy; flowing, but rarely redundant. He is, perhaps, the first British statesman whose parliamentary oratory has been really a power; and with such splendid qualifications it was little wonder that he readily became the protagonist of the Tory party. He was their mouthpiece; he gave expression to their half-articulate wishes, hounded them on in their insane attacks on the great Whig leaders, and barbed their invectives with his own trenchant wit. But, as he has himself admitted, it would be difficult to discover what object the Tories really had in view. Their only desire seems to have been to revenge themselves upon their political opponents and indirectly to assail the king. A definite policy they had not either at that time or throughout the succeeding reign. The Whigs had so far a basis of operations; they held by the Protestant succession, and were in favour of a war with France. The Tories, who, if thoroughgoing, were really Jacobites, were averse to the French war, because it indirectly weakened their party, and they did not favour the succession. But consistent adherence to principle is a thing one looks for in vain among the majority of statesmen in the reign of Anne. There never was a time in British history when the movements of politicians were regulated by such petty causes, and when great talents had to be turned to such paltry purposes. Politics became but a grand game, in which success meant office, power, wealth, and dignity; and to secure such success few hesitated at the most dishonourable means. Treason was a thing of common occurrence, and many names among the highest in English history are tarnished by acts of grossest treachery. Bolingbroke participates to the full in the spirit of his time. Never throughout his whole career can one observe the operation of a consistent policy, or trace the action of any motive higher than personal ambition. Mentally and morally he was well qualified to take a prominent place in the political struggle of the time.

The rush of popular favour to the Tory party was checked by Louis's acknowledgment of the Pretender as legitimate king of England. There was no opposition made to the proposed war, which was not interrupted by the death of William and the accession of Anne. Godolphin and Marlborough, both moderate Tories, were strongly in favour of the war, and consequently found themselves gradually drawn into harmony with the Whigs rather than with the extreme members of their own party. Several of the latter were removed from the cabinet, and among the new officials were Harley, and, curiously enough, St John, the former being made Secretary of State, the latter Secretary at War. It has been doubted to what influence St John owed this singular promotion. Harley's power was hardly great enough to effect it, and it is more than probable that it was in great part, if not entirely, the work of Marlborough, who had a very considerable affection and respect for St John, and who doubtless desired a friend of his to fill the office with which he had so many transactions. As secretary St John discharged his duties with great efficiency, and manifested the most enthusiastic admiration for Marlborough's military genius and success. Meantime Harley had been tampering with the secret springs which moved so much of the political machinery. His relative Mrs Masham was supplanting the imperious duchess of Marlborough, and through her influence the queen was becoming convinced that the interests of the nation should be confided to Harley and the Tories. She was ready to dismiss Godolphin at the first opportunity, but the Whigs were as yet too strong, and Harley's schemes having been discovered, he was in 1708 compelled to resign. St John, who can hardly be thought to have had no cognizance of what was afoot, resigned along with him, and spent two years in philosophical retirement, studying diligently and living loosely as before. During these years a gradual undercurrent of feeling swelled up against the Whig party. The war was distasteful, and its prolongation was looked upon as altogether the work of Marlborough. Above all, the queen was thoroughly alienated from her old friend and under the influence of Mrs Masham. Yet the strength of the Whig party might have enabled them to carry through their policy successfully had not an act of suicidal imprudence completely ruined them. The prosecution of Sacheverell was the signal for a perfect storm of insanely loyal feeling throughout the country. A Tory ministry

BOLBEC, a town of France, capital of a canton in the department of Lower Seine, 18 miles E.N.E. from Havre on the railway to Paris, which here passes over high embankments and a viaduct. It was burned almost to the ground in 1765, but is now a flourishing brick-built manufacturing town, well supplied with water-power by the Bolbec stream. The principal manufactures are cotton goods, woollen cloth, and leather; there are also linen factories and dye-works. Population in 1872, 9019.

BOLEYN, ANNE, or, as the name is variously spelled, Bullen, Bouleyn, Boullan, or Boulain, queen of England, and second wife of Henry VIII., was the daughter of Sir Thomas Boleyn, a distinguished politician, and Lady Elizabeth Howard, daughter of the earl of Surrey, afterwards duke of Norfolk. Considerable obscurity rests over the date of her birth, which has been variously stated as 1501 and 1507; perhaps the earlier date is the more probable. She received a very careful education, and in 1514 became maid-in-waiting to Mary Tudor, then the affianced bride of Louis XII. of France. She crossed to France in Mary's train, but did not return with her, having entered the service of Queen Claude, where she was celebrated for her beauty, talents, and accomplishments. The period of her return to England has been matter of dispute; some, following Herbert and others, would make the date about 1522, others 1527. It may be assumed with some confidence that she returned about the earlier date. About this time occurred her love affair with Percy, afterwards earl of Nort umberland, which was broken off by Wolsey, acting apparently under the directions of the jealous king. Henry seems already to have begun to direct his affections towards the fair Boleyn, who was then one of the maids of honour attached to his consort, Katherine of Aragon. He advanced her family, but is said to have been repulsed by her when he made an offer of his love. In 1527, after some absence from the court, she seems to have returned, and Henry's attentions to her became more marked than before. His passion soon opened his eyes more clearly to the sin of his marriage with his deceased brother's wife, and the subject of the divorce began to be seriously discussed. Towards 1530 Anne Boleyn was accustomed to keep state almost as queen; in 1532 she was raised to the peerage with the title of marchioness of Pembroke, and accompanied Henry in his visit to France. On January 25, 1533, according to a contemporary report, her ambition was crowned by a private marriage with Henry. On the 12th of April she was openly proclaimed queen, and the marriage was again solemnized; and on the 8th of May the king's previous marriage was declared to have been null and void. The coronation took place on the 19th of May, and on the 7th September, a princess, the famous Elizabeth, was born.

Little is known of the new queen's married life. She to some extent favoured the Reformers, and countenanced the translation of the Bible. In January 1536 she gave birth to a prince, still-born. It is said that this mishap was occasioned by her suddenly becoming aware of Henry's attentions to Lady Jane Seymour. However this may be, Henry's superstitious fears seem to have been roused by the want of a male heir, and his fancy for Anne Boleyn had been replaced by a new passion. In April 1536 a committee sat privately to inquire into certain accusations of adultery against the queen. A special commission was called on the 24th April, and orders were issued for the arrest of the Viscount Rochford, the queen's brother, Sir Henry Norris, Sir Wm. Brereton, Sir Francis Weston, and Mark Smeton, all her alleged paramours. At the same time writs were issued for a new parliament. On the 2d May the queen was arrested and summoned before the privy council. Smeton, Norris, and Weston were afterwards examined, and of these Smeton confessed, though it was said under torture. Norris is thought to have made some admission, which, however, he afterwards withdrew. All three were committed to the Tower, to an apartment in which the queen was also consigned. Henry wrote to her, holding out hopes of pardon if she would be open and honest. Her reply, however, strongly affirms her innocence, and its general tone goes far in her favour. (The authenticity of the queen's letter has been doubted, though on slight grounds, by Mr Froude.) The juries of Middlesex and Kent, before whom proceedings opened, found true writs charging the queen with adultery, committed with the above-named Rochford, Brereton, Weston, Norris, and Smeton, and all with conspiring against the king's life. On the 12th May, Brereton, Norris, Weston, and Smeton were tried at Westminster, found guilty, and condemned. On the 15th Anne Boleyn and her brother were tried before twenty-seven peers, found guilty, and sentenced. On the 17th Smeton was hanged, the others beheaded. Their remarks on the scaffold were general, and can be interpreted fairly in neither way. Before the queen's execution she is said to have confessed to Cranmer some previous impediment which rendered her marriage with the king null and void, but what the confession was is absolutely unknown. On the 19th May she suffered death on Tower Green. On the next day Henry was married to Jane Seymour. Over the whole episode of Anne Boleyn's trial and execution the deepest obscurity rests. All traces of the evidence have vanished, and the conflicting judgments of historians, it must be confessed, seem generally to be determined by the bias of the individual writer.

See *State Trials*, where Burnet and the older writers are quoted; Strickland, *Lives of the Queens of England*; Miss Binger, *Life of A. Boleyn*; and the histories of Lingard and Froude.

BOLI, a town of Asiatic Turkey, in Anatolia, situated about 85 miles N.W. of Angora, on the Philios Chai, to the south of the Boli Dagh, in 31° 40′ E. long. and 40° 45′ N. lat. It is the capital of a sandjak and the seat of a governor, and contains a ruined castle and numerous mosques and baths, nowise remarkable in their structure. Cotton and leather are manufactured; the country around is fertile, and in the neighbourhood is a forest, from which Constantinople is largely supplied with wood. There are warm springs in the vicinity. Boli is built not far from what is regarded by Leake as the ruins of Hadrianopolis, where many marble fragments with Greek inscriptions are still found. The population is conjecturally stated at 10,000.

BOLINGBROKE, HENRY ST JOHN, VISCOUNT, was born in October 1678. His father, Sir Henry St John, the descendant of an old and noble family, was a noted rake of the Restoration period, who continued to live his life of pleasure and indolence for upwards of ninety years. Of his mother little is known, save that she was a daughter of the earl of Warwick. The most prominent characteristics seem to have been copiousness and readiness, extreme fluency, and spontaneity, combined with a brilliant felicity of phrase, the right expression seeming to spring up naturally along with the thought to be expressed. His sentences are mostly massive and balanced, yet never heavy; flowing, but rarely redundant. He is, perhaps, the first British statesman whose parliamentary oratory has been really a power; and with such splendid qualifications it was little wonder that he readily became the protagonist of the Tory party. He was their mouthpiece; he gave expression to their half-articulate wishes, hounded them on in their insane attacks on the great Whig leaders, and barbed their invectives with his own trenchant wit. But, as he has himself admitted, it would be difficult to discover what object the Tories really had in view. Their only desire seems to have been to revenge themselves upon their political opponents and indirectly to assail the king. A definite policy they had not either at that time or throughout the succeeding reign. The Whigs had so far a basis of operations; they held by the Protestant succession, and were in favour of a war with France. The Tories, who, if thoroughgoing, were really Jacobites, were averse to the French war, because it indirectly weakened their party, and they did not favour the succession. But consistent adherence to principle is a thing one looks for in vain among the majority of statesmen in the reign of Anne. There never was a time in British history when the movements of politicians were regulated by such petty causes, and when great talents had to be turned to such paltry purposes. Politics became but a grand game, in which success meant office, power, wealth, and dignity; and to secure such success few hesitated at the most dishonourable means. Treason was a thing of common occurrence, and many names among the highest in English history are tarnished by acts of grossest treachery. Bolingbroke participates to the full in the spirit of his time. Never throughout his whole career can one observe the operation of a consistent policy, or trace the action of any motive higher than personal ambition. Mentally and morally he was well qualified to take a prominent place in the political struggle of the time.

The rush of popular favour to the Tory party was checked by Louis's acknowledgment of the Pretender as legitimate king of England. There was no opposition made to the proposed war, which was not interrupted by the death of William and the accession of Anne. Godolphin and Marlborough, both moderate Tories, were strongly in favour of the war, and consequently found themselves gradually drawn into harmony with the Whigs rather than with the extreme members of their own party. Several of the latter were removed from the cabinet, and among the new officials were Harley, and, curiously enough, St John, the former being made Secretary of State, the latter Secretary at War. It has been doubted to what influence St John owed this singular promotion. Harley's power was hardly great enough to effect it, and it is more than probable that it was in great part, if not entirely, the work of Marlborough, who had a very considerable affection and respect for St John, and who doubtless desired a friend of his to fill the office with which he had so many transactions. As secretary St John discharged his duties with great efficiency, and manifested the most enthusiastic admiration for Marlborough's military genius and success. Meantime Harley had been tampering with the secret springs which moved so much of the political machinery. His relative Mrs Masham was supplanting the imperious duchess of Marlborough, and through her influence the queen was becoming convinced that the interests of the nation should be confided to Harley and the Tories. She was ready to dismiss Godolphin at the first opportunity, but the Whigs were as yet too strong, and Harley's schemes having been discovered, he was in 1708 compelled to resign. St John, who can hardly be thought to have had no cognizance of what was afoot, resigned along with him, and spent two years in philosophical retirement, studying diligently and living loosely as before. During these years a gradual undercurrent of feeling swelled up against the Whig party. The war was distasteful, and its prolongation was looked

would evidently meet with popular approval, and Anne had therefore no hesitation in dismissing Godolphin and the Whigs. Harley became Chancellor of the Exchequer and virtually premier; St John was made Secretary of State.

The political problem, how, under all contingencies, to retain power, was somewhat complicated. The queen's health made the succession the main question. Now, the accession of the Elector meant the restoration of the Whigs to power. It was hardly possible for the Tory leaders to oust the Whig party from the graces of the House of Hanover, with whom their policy was so knit up. Prudence, therefore, as well as principle, made them lean towards the exiled House of Stuart, and for a time extreme Tory was synonymous with Jacobite. But the hopes of James to a great extent depended on the assistance of France, and consequently peace with France became their primary object. To attain it they were urged also by the loudly expressed wishes of a large section of the people, and by their hatred of the Whigs, with whom the war was identified. Active steps in the matter were taken mainly by St John, and in the beginning of 1712 he had at last brought affairs to such a pass that the duke of Ormond, who had superseded Marlborough, received secret orders not to attack the French, while private intimation of this order was sent to the French Government. Arrangements were then made with the French minister De Torcy, whereby the fundamental articles of the league with the allies were broken, Britain engaging to enter into a separate peace with France, receiving certain special advantages, and quietly abandoning some of the allies, as the Catalans. Nothing can possibly extenuate the baseness of these proceedings, and our judgment of them cannot be altered by our opinion as to the advisability of the peace. The Whig party were wholly unable to throw any obstacles in the way; their majority in the House of Lords had been swamped by the creation of twelve new peers; and Walpole had been impeached on a petty charge and committed to the Tower. Finally, St John, now Viscount Bolingbroke, visited Paris to push on negotiations so that peace might be announced to next Parliament. It has been said, though he himself denied it, that during this visit he had interviews with the Pretender. In April 1713 the famous treaty of Utrecht was signed, and the Parliament of that year had the articles read to them. This, however, had not the effect anticipated by Bolingbroke. There was a lurking feeling of discontent with regard to it, and the commercial articles, bearing on trade with France, excited great indignation among the mercantile classes.

Bolingbroke and the Tories seemed, however, to be at the zenith of their power; but the foundations of that power were unstable, and there was dissension among the leaders. Harley had become earl of Oxford, and Bolingbroke was indignant at receiving only the rank of viscount. His anger was increased on failing to receive the garter vacant by the death of Godolphin. The disputes between the former allies became open and violent. By unscrupulous bribery Bolingbroke managed to secure the interest of Mrs Masham, and through her wrought upon the queen. In the Parliament of 1714 he dealt the death-blow to Oxford's power, by compelling him to vote upon the Schism Bill; and finally, on the 27th July, after a stormy discussion, which greatly excited the queen, Oxford was dismissed. Bolingbroke, however, had but a brief taste of power, for on the 30th the queen was seized with apoplexy. At the council held upon the emergency the dukes of Argyle and Somerset boldly presented themselves, and proposed and carried a resolution that the duke of Shrewsbury should be recommended as Lord Treasurer. Bolingbroke was obliged to yield. Anne was able to give assent; the Whig party had already made all their arrangements, and immediately on the queen's death (August 1) the Elector was proclaimed king, and special messengers were despatched to bring him over. Bolingbroke and his friends seemed bewildered; they were, indeed, thoroughly taken by surprise, and their half-formed schemes disconcerted. Atterbury alone urged Bolingbroke boldly to proclaim James, but either the courage of the latter failed, or, as is more probable, his intentions were not sufficiently definite. It is not an unreasonable supposition that, had a fair time been granted to him, he would have endeavoured to make favour with the House of Hanover. Any such hope was then out of the question; the duties of his office were transferred temporarily to Addison, and within the month in which the queen died he was formally dismissed. It was soon known that the new Parliament, who were mainly Whigs, intended to impeach Oxford and Bolingbroke for their share in the recent peace. From what we now know of the actual accusation, it is plain that it did not amount to high treason. Had there been nothing farther it would have been the best plan to have stayed and faced the trial. This, accordingly, was done by Oxford; but Bolingbroke, after showing himself ostentatiously in public, fled over to France in disguise, even before the impeachment had been made in the House. In the letter he left behind him for Lord Lansdowne he gives as his excuse that he had certain and repeated informations from some who were in the secret of affairs that a resolution was taken to pursue him to the scaffold. In the famous letter to Sir Wm. Windham he takes somewhat different ground, and accounts for his flight from his intense dislike of Oxford, and his resolution not to be associated with him in any way. It was not till the 10th June that he was formally impeached; on 6th August he was attainted and summoned to appear before the 10th September. On the 16th September, he not having made his appearance, his name was struck off the list of peers, and sentence of banishment was passed. Long before this, however, Bolingbroke had thrown in his lot with the Pretender. He had secret interviews with the duke of Berwick immediately after his arrival in Paris, while professing the most loyal sentiments to Lord Stair, the British ambassador, and in the month of July he was formally installed as Secretary of State to the prince. Whatever plans he might have hoped to carry through in this capacity were thoroughly thwarted by the numberless irregular agents and advisers who swarmed about the petty court, and by the impracticable disposition of the prince himself. The expedition to Scotland, undertaken against Bolingbroke's advice, proved a complete failure; and in February 1716 he was dismissed with scant ceremony from the prince's service, while a formal impeachment was drawn up, accusing him of dilatoriness and want of energy. Rumour was busy with his name, and every species of treachery was imputed to him. The celebrated letter to Sir Wm. Windham, in many respects the best of his writings, was drawn up in the following year, and contains an elaborate sketch of the events of his political career and a justification of his proceedings. The letter may have been circulated to a slight extent in print or in manuscript, but it was undoubtedly not made public till 1753, two years after Bolingbroke's death. It is a skilful piece of work, written with great apparent candour, but inconsistent with known facts, and throwing no satisfactory light on the complicated transactions in which the writer had been involved.

His efforts to ingratiate himself with the new dynasty in England were unavailing, and from this time onwards to his death he led a life of enforced inactivity. He was for ever debarred from the arena of political strife, and though he incessantly hovered round the outskirts, he was unable to effect an entrance. He plunged deeply into philosophical

studies, and would fain have had his friends believe that he had thoroughly and voluntarily resigned himself to a life of studious retirement. He took up his abode at La Source, and in 1720, two years after the death of his first wife, married the Marquise de Villette, for whom he seems to have had a sincere affection. In 1723, by bribing the duchess of Kendal, a removal of part of his sentence was attained; he was permitted to return to England, and, by a special bill, passed two years later, was allowed to enjoy his first wife's property. He bought a magnificent estate at Dawley; and, while keeping up the appearance of single-minded devotion to study, plunged eagerly into as much of political intrigue as was open to him. He had tried in vain to conciliate Walpole, and seems to have seen that during that minister's tenure of power he could never recover his position. He accordingly united himself to the dissatisfied section of the Whigs led by Pulteney, and tried to organize out of them and the remnant of the Tories an opposition to Walpole. His aid was lent not only in preparing speeches for Windham, Pulteney, and others, who for a time were little more than his mouthpieces, but in written attacks upon the minister. His papers in the *Craftsman*, which gave that journal a circulation exceeding even that of the *Spectator*, are masterpieces of vigorous English. In their collected form as the *Dissertation on Parties* and *Oldcastle's Remarks on History*, they are valuable contributions to our knowledge of the political movements of the period. At one time, indeed, it seemed that the opposition would succeed in driving Walpole from the field. The outcry against his Excise Bill was strong, and his majority in the House was seriously diminished, but he was too firmly rooted to be easily moved; and in 1735 he retaliated on Bolingbroke by a significant and threatening speech. So evident was it that he had obtained an insight into intrigues which could not stand investigation, that Bolingbroke took alarm and a second time fled to France. Other motives, such as pecuniary embarrassments, may have contributed to force him to this step, and there can be little doubt that his reputation was of a nature seriously to damage any party with whom he united. He found that Pulteney was anxious to get rid of him, and felt with some bitterness that, like an old actor, he must retire from the political stage before being hissed off. After this second retreat he settled at Chanteloup, in Touraine, whence he paid two or three visits to England. Finally, in 1743, after the death of his father, he took up his residence at Battersea, and, finding the new statesmen little disposed to hearken even to his counsels, endeavoured to devote himself entirely to philosophy. He died at Battersea on the 12th December 1751.

Of Bolingbroke as an author but little can be said. The question asked a very few years after his death, "Who now reads Bolingbroke?" may be put with tenfold significance now. The influence of his writings on English literature has been quite inappreciable, and probably the works of few men of such ability have been so little read. Yet this neglect is in some respects undeserved. His writings may be regarded in two aspects,—as specimens of English prose, and as positive contributions to history, politics, and philosophy. In the latter aspect their worth is indeed small. His historical treatises, while containing much that is of interest and importance, are over-weighted by the constant reference to the peace of Utrecht, the defence of which is almost their sole object. It would be difficult to extract from the *Dissertation on Parties*, the *Idea of a Patriot King*, or the *Letters on Patriotism* anything like a consistent philosophy of government. No one has expounded better than Bolingbroke the fundamental principles of Whig policy, and yet his ideal of a king is a sovereign who, from various qualities, is able to retain nearly absolute power, and to govern without the intervention of party spirit. In philosophy he occupies but a subordinate place in the long line of English writers who drew their inspiration from Locke, and who gave the key-note to the religious enlightenment of the 18th century. He is a deist, and from the basis of the sensational theory of knowledge attacks revealed religion with force quite inferior to Toland or Tindal. Bolingbroke's philosophical works are indeed insufferably wearisome, and it is only in them that his style ever flags and grows cumbersome, for his other writings are in many respects the perfection of English prose style, and can stand comparison even with the finished compositions of Addison. For ease, grace, and oratorical vehemence and energy, the *Letter to Sir Wm. Windham* and the dedication of the *Dissertation on Parties* are nearly unsurpassed. Bolingbroke clearly was at his best when roused by strong feeling, and his most vigorous passages are those which would naturally have been spoken. That none of his parliamentary orations have come down to us is matter of deepest regret, even though our estimate of them be lower than Pitt's.

Bolingbroke's works were published in 5 vols. 4to, by David Mallet, 1753-54. Later editions have generally prefixed to them the *Life* by Goldsmith, a compilation of little value. Two volumes of *Correspondence* were published by Parke in 1798. Materials for Bolingbroke's life are to be found in the Stuart papers, Marchmont papers, Coxe's *Life of Marlborough*, Swift's *Journal* and *History of the last Four Years of Queen Anne*, Somerville's *Queen Anne*, and Stanhope's *Reign of Queen Anne* and *History of England*, particularly vols. i. and ii. Some special information will be found in De Torcy's *Mémoires*, and Mignet's *Negociacions relatifs à la Succession d'Espagne*. See also G. W. Cooke, *Memoirs of Bolingbroke*, 2 vols., 1835; Rémusat, *Angleterre au XVIII Siècle*, vol. i.; Macknight, *Life of Bolingbroke*, 1863. (R. AD.)

BOLIVAR, Simon, the hero of South American independence, was born in the city of Caracas, Venezuela, on the 24th July 1783. His father was Juan Vicente Bolivar y Ponte, and his mother Maria Concepcion Palacios y Sojo, both descended of noble families in Venezuela. After acquiring the elements of a liberal education at home, Bolivar was sent to Europe to prosecute his studies, and with this view repaired to Madrid, where he appears to have resided for several years. Having completed his education, he spent some time in travelling, chiefly in the south of Europe, and visited the French capital, where he was an eye-witness of some of the last scenes of the Revolution. Returning to Madrid, he married, in 1801, the daughter of Don N. Toro, uncle of the marquis of Toro in Caracas, and embarked with her for America, intending, it is said, to devote himself to the improvement of his large estate. But this plan was frustrated by the premature death of his young wife, who fell a victim to yellow fever; and Bolivar again visited Europe, in order, by change of scene, to alleviate the sorrow occasioned by this bereavement.

On his return home in 1809 he passed through the United States, where, for the first time, he had an opportunity of observing the working of free institutions; and soon after his arrival in Venezuela he appears to have identified himself with the cause of independence which had already agitated the Spanish colonies for some years. Being one of the promoters of the movement at Caracas in April 1810, he received a colonel's commission from the revolutionary junta, and was associated with Luis Lopez Mendez in a mission to the court of Great Britain. Venezuela declared its independence of the mother country on July 5, 1811, and in the following year the war commenced in earnest by the advance of Monteverde with the Spanish troops. Bolivar was intrusted with the command of the important post of Puerto Cabello, but not being supported he had to evacuate the place; and owing to the inaction of Miranda the Spaniards recovered their hold over the country.

Like others of the revolutionists Bolivar took to flight,

and succeeded in reaching Curaçao in safety. He did not, however, remain long in retirement, but in September 1812, hearing of important movements in New Granada, repaired to Carthagena, where he received a commission to operate against the Spanish troops on the Magdalena River. In this expedition he proved eminently successful, driving the Spaniards from post to post, until arriving at the confines of Venezuela he boldly determined to enter that province and try conclusions with General Monteverde himself. His troops did not number more than 500 men; but, in spite of many discouragements, he forced his way to Merida and Truxillo, towns of some importance in the west of Venezuela, and succeeded in raising the population to his support. Forming his increased forces into two divisions, he committed the charge of one to his colleague Rivas, and pushing on for Caracas the capital, issued his decree of "war to the death." A decisive battle ensued at Lastoguanes, where the Spanish troops under Monteverde sustained a crushing defeat. Caracas was entered in triumph on the 4th of August 1813, and Monteverde took refuge in Puerto Cabello. General Mariño effected the liberation of the eastern district of Venezuela, and the patriots obtained entire possession of the country in January 1814. This success was, however, of very brief duration. The royalists, effectually roused by the reverses they had sustained, concentrated all their means, and a number of sanguinary encounters ensued. Bolivar was eventually defeated by Boves near Cura, in the plains of La Puerta, and compelled to embark for Cumana with the shattered remains of his forces. Caracas was retaken by the Spaniards in July; and before the end of the year 1814 the royalists were again the undisputed masters of Venezuela. From Cumana Bolivar repaired to Carthagena, and thence to Tunja, where the revolutionary congress of New Grenada was sitting. Here, notwithstanding his misfortunes and the efforts of his personal enemies, he was received and treated with great consideration. The congress appointed him to conduct an expedition against Santa Fé de Bogota, where Don Cundinamarca had refused to acknowledge the new coalition of the provinces. In December 1814 he appeared before Bogota with a force of 2000 men, and obliged the recalcitrant leaders to capitulate,—a service for which he received the thanks of congress. In the meanwhile Santa Martha had unfortunately fallen into the hands of the royalists, and Bolivar was ordered to the relief of the place. In this, however, he was not successful, General Morillo having landed an overwhelming Spanish force. Hopeless of the attempt, he resigned his commission and embarked for Kingston, Jamaica, in May 1814. While residing there an attempt was made upon his life by a hired assassin, who, in mistake, murdered his secretary.

From Kingston Bolivar repaired to Aux Cayes in Hayti, where he was furnished with a small force by President Petion. An expedition was organized, and landed on the mainland in May 1816, but proved a failure. Nothing daunted, however, he obtained reinforcements at Aux Cayes, and in December landed first in Margarita, and then at Barcelona. Here a provisional government was formed, and troops were assembled to resist Morillo, who was then advancing at the head of a strong division. The hostile forces encountered each other on the 16th of February 1817, when a desperate conflict ensued, which lasted during that and the two following days, and ended in the defeat of the royalists. Morillo retired in disorder, and being met on his retreat by Paez with his *llaneros*, suffered an additional and more complete overthrow. Being now recognized as commander-in-chief, Bolivar proceeded in his career of victory, and before the close of the year had fixed his headquarters at Angostura on the Orinoco. At the opening of the congress which assembled in that city on the 15th February 1819 he submitted an elaborate exposition of his views on government, and concluded by surrendering his authority into the hands of congress. Being, however, required to resume his power, and retain it until the independence of the country had been completely established, he reorganized his troops, and set out from Angostura, in order to cross the Cordilleras, effect a junction with General Santander, who commanded the republican force in New Grenada, and bring their united forces into action against the common enemy. This bold and original design was crowned with complete success. In July 1819 he entered Tunja, after a sharp action on the adjoining heights; and on the 7th of August he gained the victory of Bojaca, which gave him immediate possession of Bogota and all New Grenada.

This campaign is unquestionably Bolivar's most brilliant achievement, and deserves much of the praise which has been lavished on it. His return to Angostura was a sort of national festival. He was hailed as the deliverer and father of his country, and all manner of distinctions and congratulations were heaped upon him. Availing himself of the favourable moment, he obtained the enactment of the fundamental law of 17th December 1819, by which the republics of Venezuela and New Grenada were henceforth to be united in a single state, under his presidency, by the title of the Republic of Colombia. The seat of government was also transferred provisionally to Rosario de Cucuta, on the frontier of the two provinces, and Bolivar again took the field. Being now at the head of the most numerous and best appointed army the republicans had yet assembled, he gained important advantages over the Spaniards under Morillo, and on the 25th November 1820 concluded at Truxillo an armistice of six months, probably in the hope that the Spaniards would come to terms, and that the further effusion of blood might be spared. If such were his views, however, they were disappointed. Morillo was recalled, and General Torre assumed the command. The armistice was allowed to expire, and a renewal of the contest became inevitable. Bolivar therefore resolved, if possible, to strike a decisive blow; and this accordingly he did at Carabobo, where, encountering Torre, he so completely routed the Spaniards, that the shattered remains of their army were forced to take refuge in Puerto Cabello, where two years after they surrendered to Paez. The battle of Carabobo may be considered as having put an end to the war in Venezuela. On the 29th June 1820 Bolivar entered Caracas, and by the close of the year the Spaniards were driven from every part of the province except Puerto Cabello. The next step was to secure, by permanent political institutions, the independence which had been so dearly purchased; and, accordingly, on the 30th of August 1821, the constitution of Colombia was adopted with general approbation, Bolivar himself being president, and Santander vice-president.

There was, however, more work for him to do. The Spaniards, though expelled from Colombia, still held possession of the neighbouring provinces of Ecuador and Peru; and Bolivar determined to complete the liberation of the whole country. Placing himself at the head of the army, he marched on Quito in Ecuador. A severe battle was fought at Pichincha, where, by the prowess of his colleague Sucre, the Spaniards were routed, and Quito was entered by the republicans in June 1822. Bolivar then marched upon Lima, which the royalists evacuated at his approach; and entering the capital in triumph, he was invested with absolute power as dictator, and authorized to call into action all the resources of the country. Owing, however, to the intrigues of the republican factions in Peru he was forced to withdraw to Truxillo, leaving the capital to the mercy of the Spaniards under Canterac, by

whom it was immediately occupied. But this misfortune proved only temporary. By June 1824 the liberating army was completely organized; and taking the field soon after, it routed the vanguard of the enemy. Improving his advantage, Bolivar pressed forward, and on the 6th of August defeated Canterac on the plains of Junin, after which he returned to Lima, leaving Sucre to follow the royalists in their retreat to Upper Peru,—an exploit which the latter executed with equal ability and success, gaining a decisive victory at Ayacucho, and thus completing the dispersion of the Spanish force. The possessions of the Spaniards in Peru were now confined to the castles of Callao, which Rodil maintained for upwards of a year, in spite of all the means that could be employed for their reduction. In June 1825 Bolivar visited Upper Peru, which having detached itself from the government of Buenos Ayres, was formed into a separate state, called Bolivia, in honour of the liberator. The first congress of the new republic assembled in August 1825, when Bolivar was declared perpetual protector, and requested to prepare for it a constitution of government.

We now come to that period in the liberator's career when his care was directed to the administration of the affairs of the freed provinces. He had been successful in raising those districts to the position of independent states, and now devoted himself to the framing of such laws as seemed to him most suitable to the inhabitants. His endeavours to satisfy his countrymen in this respect did not always meet with encouragement, and sometimes exposed him to slander. In December 1824 Bolivar convoked a constituent congress for the February following; but this body, taking into consideration the unsettled state of the country, thought it proper to invest him with dictatorial power for another year. A grant of a million dollars was offered him but declined, and the congress adjourned, leaving the dictator absolute governor of Peru. His project of a constitution for Bolivia was presented to the congress of that state on the 25th May 1826, accompanied with an address, in which he embodied his opinions respecting the form of government which he conceived most expedient for the newly-established republics. This code, however, did not give satisfaction. Its most extraordinary feature consisted in the provision for lodging the executive authority in the hands of a president for life, without responsibility and with power to nominate his successor, a proposal which alarmed the friends of liberty, and excited lively apprehensions amongst the republicans of Buenos Ayres and Chili; whilst in Peru, Bolivar was accused of a design to unite into one state Colombia, Peru, and Bolivia, and to render himself perpetual dictator of the confederacy.

In the meanwhile the affairs of Colombia had taken a turn which demanded the presence of Bolivar in his own country. During his absence Santander had administered the government of the state ably and uprightly, and its independence had been recognized by other countries. But Paez, who commanded in Venezuela, having been accused of arbitrary conduct in the enrolment citizens of Caracas in the militia, refused obedienc summons of the senate, and placed himself in a open rebellion against the Government, being encouraged by a disaffected party in the northern departments who desired separation from the rest of the republic.

Accordingly, having intrusted the government to a council nominated by himself, with Santa-Cruz at its head, Bolivar set out from Lima in September 1826, and hastening to Bogota, arrived there on the 14th November. He immediately assumed the extraordinary powers which by the constitution the president was authorized to exercise in case of rebellion. After a short stay in the capital he pressed forward to stop the effusion of blood in Venezuela, where matters had gone much farther than he could have contemplated. On the 31st December he reached Puerto Cabello, and the following day he issued a decree offering a general amnesty. He had then a friendly meeting with Paez and soon after entered Caracas, where he fixed his headquarters, in order to check the northern departments, which had been the principal theatre of the disturbances. In the meanwhile Bolivar and Santander were re-elected to the respective offices of president and vice-president, and by law they should have qualified as such in January 1827. In February, however, Bolivar formally resigned the presidency of the republic, at the same time expressing a determination to refute the imputations of ambition which had been so freely cast upon him, by retiring into private life, and spending the remainder of his days on his patrimonial estate. Santander combated this proposal, urging him to resume his station as constitutional president, and declaring his own conviction that the troubles and agitations of the country could only be appeased by the authority and personal influence of the liberator himself. This view being confirmed by a resolution of congress, although it was not a unanimous one, Bolivar decided to resume his functions, and he repaired to Bogota to take the oaths. Before his arrival, however, he issued simultaneously three separate decrees,—one granting a general amnesty, another convoking a national convention at Ocaña, and a third for establishing constitutional order throughout Colombia. His arrival was accelerated by the occurrence of events in Peru and the southern departments, which struck at the very foundation of his power. Not long after his departure from Lima, the Bolivian code had been adopted as the constitution of Peru, and Bolivar had been declared president for life on the 9th December 1826, the anniversary of the battle of Ayacucho. At this time the Colombian auxiliary army was cantoned in Peru, and the third division, stationed at Lima, consisting of veteran troops under Lara and Sands, became distrustful of Bolivar's designs on the freedom of the republic. Accordingly, in about six weeks after the adoption of Bolivar's new constitution, a counter-revolution in the government of Peru was effected by this body of dissatisfied veterans, and the Peruvians, availing themselves of the opportunity, abjured the Bolivian code, deposed the council appointed by the liberator, and proceeded to organize a provisional government for themselves. After this bloodless revolution the third division embarked at Callao on the 17th March 1827, and landed in the southern department of Colombia in the following month. Intelligence of these events reached Bolivar while in the north of Colombia, and he lost no time in preparing to march against the refractory troops, who formerly had placed such implicit confidence in him. But he was spared the necessity of coming to blows, for the leaders, finding the government in the hands of the national executive, had peaceably submitted to General Ovando. In the meanwhile Bolivar had accepted the presidency, and resumed the functions belonging to his

did not conceal their conviction that a stronger and more permanent form of government was essential to the public welfare. The latter view seems to have prevailed. In virtue of a decree, dated Bogota, the 27th August 1828, Bolivar assumed the supreme power in Colombia, and continued to exercise it until his death, which took place at San Pedro, near Santa Martha, on the 17th December 1830.

In the career of this remarkable man, which was often embittered and was perhaps shortened by the suspicions and slanders of his colleagues in the work of liberation, certain circumstances, apparently well established, stand out, which deserve particular mention. He expended nine-tenths of a splendid patrimony in the service of his country; and although he had for a considerable period unlimited control over the revenues of three countries,—Colombia, Peru, and Bolivia,—he died without a shilling of the public money in his possession. He conquered the independence of three states, and called forth a spirit in the southern portion of the New World which can never be extinguished. He purified the administration of justice; he encouraged the arts and sciences; he fostered national interests; and he induced other countries to recognize that independence which was in a great measure the fruit of his own exertions. Bolivar's remains were removed in 1842 to Caracas, where a monument was erected to his memory; and in 1858 the Peruvians followed the example by erecting an equestrian statue of the liberator in Lima.

BOLIVIA

Plate XVII. THIS name was given in honour of Bolivar (see last article) to a state in South America, formed in 1825 from the provinces of Upper Peru which formerly constituted part of the vice-royalty of Buenos Ayres. The bulk of the country extends from 10° to 23° S. lat., and from 58° to 71° W. long., and it is bounded on the N. by Peru and Brazil, on the E. by Brazil and Paraguay, on the S. by the Argentine Republic and Chili, and on the W. by the Pacific Ocean and Peru. The greater part of Bolivia is a mountainous and elevated country, more particularly at its western and central parts; but towards the east it becomes much less so, and at length terminates in extensive plains, which are bounded on the east by Brazil. From the Pacific coast the southern boundary of Bolivia runs along the 24th parallel of latitude (the limit decided by treaty with Chili in August 1866), to as far as the crest of the Andes; turning S. it follows the line of the mountains to 26° S. lat., in which parallel it crosses the plateau to the inner Cordillera, along which it lies N.N.E. to the 22d parallel. This line of latitude forms the boundary of territory which is certainly Bolivian, as far as the River Paraguay; but Bolivia, in common with the Argentine Republic and Paraguay, has claims on the unexplored territory of the Gran Chaco, which lies south of this line, and between the rivers Pilcomayo and Paraguay. From 22° on the River Paraguay, the frontier with Brazil was decided, by treaty of March 1867, to be a line following that river northward to the Bahia Negra in 20° 11′, along the Negra to its termination, and thence through the midst of the lagoons of Caceres, Mandioré, Gaiba, and Uberaba (lying immediately west of the Paraguay River), to Corixa Grande; thence in a straight line to Boa Vista and the source of the Verde; down that river to the Guapore, and along the latter to where the Beni joins it in 10° 20′ S.; thence in a straight line towards the source of the River Javary (in 7° S.) The present Government of Bolivia appears inclined, however, to repudiate this treaty, and to return to the older frontier, which included the tributaries of the Amazons as far as 6° 28′ S. On the Peruvian or western frontier the boundary follows a more or less northerly direction from the mouth of the River Loa in Atacama, along the Cordillera, crossing Lake Titicaca, and passing north thence to the line running from the Beni to the Javary.

Boundaries and divisions.

Before the formation of the republic, Bolivia, or the former province of Charcas, consisted of four great districts or "intendencias," which were under the rule of the viceroy of Rio de la Plata. These were—

1. Santa Cruz, formed of the districts of its bishopric—Mojos, Chiquitos, Santa Cruz, Valle Grande, Misque, and the special jurisdiction of its capital Cochabamba;
2. La Paz, consisting of the dioceses of its bishopric;
3. Potosi, comprising Tarija, Chichas, Lipez, Atacama, Porco, and Chayanta;
4. The province of La Plata, which embraced all remaining portions of the archbishopric.

At the present time the republic is divided politically into departments, provinces, and cantons. The departments, which are named La Paz de Ayacucho, Cochabamba, Potosí, Chuquisaca, Oruro, Santa Cruz de la Sierra, Tarija, Beni, and Atacama, have each one or two capital towns; the provinces and cantons have also each its chief place. Each department has a governor, who stands in direct communication with the Government; the subdivisions have their corregidors and alcaldes, who are subject to the governor.

The westerly departments of La Paz, Oruro, and Potosi are situated in the highest regions of the plateau of Bolivia, and are more valuable on account of their mineral riches than for their vegetable products, of which a coarse grass is characteristic. The first consists of a series of high ranges and deep valleys, in which the climate and production vary with the elevation; the second lies also in the high table-land or Puna region; both are rich in veins of gold, silver, and tin, but the mining of these has not yet been fully developed. The third, Potosi, belongs entirely to the highest regions of Bolivia, and is bare and dry, with a cold and rude but healthy climate; this is the greatest mining region of the country.

The central departments of Cochabamba, Chuquisaca, and Tarija lie partly on the high plateau, partly on the lower slopes and plains eastward, and pass thus through the whole series of changing climates and zones of production, from the bare high land to the tropical regions of the low lands. The first is eminently the granary of Bolivia and southern Peru, excelling in the cultivation of wheat; the industries of woollen and cotton manufactures are also most highly developed in the department, but its mines are not worked. Chuquisaca, of which only a third part lies in the high land, is also a vegetable growing region, in which wheat, barley, rice, peas, vines, and all sorts of vegetables are cultivated; cattle and horses are also numerous. The forests of this department and of Tarija, which slope down to the wooded and pastoral plains of the tributaries of the Paraguay, afford many species of valuable timber.

The departments of Beni (or Veni) and Santa Cruz de la Sierra lie altogether in the low lands of the east, stretching to the Rio Maderia and the Paraguay. The former is as yet little explored, but is a land of tropical forests, rivers, and swamps, with an unhealthy climate. Santa Cruz is also characterized by a hot, damp atmosphere, but produces garden and field fruits in astonishing richness,—coffee, cocoa, vanilla, sugar-cane, maize, and cotton. The forests of both of these departments afford an infinity of valuable

timber trees, and in the latter there is much pasture land well fitted for cattle breeding.

The department of Atacama, which belongs geographically either to Peru or Chili, forms the only part of Bolivia which comes into contact with the ocean, and is situated between the Andes and the Pacific coast. It is almost entirely desert and sterile, has many volcanoes, and is characterized by rapid changes of temperature; it is almost destitute of population, and is only inhabited in those parts of the coast in which valuable guano deposits are found, or where the nitrate deposits and silver mines in the interior are worked. Near its northern limit is situated the small port of Cobija, the only avenue by which foreign articles of commerce can enter the Bolivian Republic without the payment of transit duties. It has obtained peculiar and valuable privileges as an encouragement to the introduction of merchandise by this route, in preference to the more convenient routes by the Puertos Intermedios, belonging to the Republic of Peru. But the arid nature of the surrounding country, and the great scarcity of water, must greatly retard its advancement, since not only are the inhabitants scantily supplied with this necessary of life, but the mules employed in transporting goods into the interior are exposed to great hardships.

Mountains. Western Bolivia is the highest and most mountainous country of the two Americas. Five separate systems of mountains, curving from Peru in the north-west and passing south into Chili, may be distinguished as forming its high land. Nearest the Pacific is the range of the outlying *coast mountains*, which does not exceed 5000 feet in altitude. The range of the true *Andes* rises farther inland, forming part of the vast chain which extends along the whole of America; in Bolivia it attains an average height of 15,000 feet, and has a general width of 20 miles, having its highest known point here in the volcano of Sahama, 23,000 feet in elevation. Next follows the central system of the *Cordillera Real*, also named the eastern Cordillera, presenting a succession of sharp, rugged peaks, reaching up into the region of eternal ice and snow, higher generally than the Andes, but less massive: the peaks of Illimani (21,300 feet) and Sorata (24,800 feet) are its culminating points. Between the Andes and the Cordillera Real there are various *Serrania* or isolated groups of mountains, and single cerros of less altitude, rising from the enclosed plateau to 17,000 feet in some instances. The last system is that of the numerous minor Cordilleras, which run south-eastward from the Cordillera Real into the lowlands of eastern Bolivia, of which the most important is that of Cochabamba, stretching out to 62° 40′ E. long. The elevation of the snow line in the highlands of Bolivia appears to vary between 16,000 and 18,000 feet, modified in many cases by the aspect of the mountains and the nature of the country surrounding them, being raised where heat is powerfully reflected from the surface of the bare high plains, or lowered where the mountains are exposed to cold southerly winds. Volcanoes are frequent in the Andes and coast ranges; those of Sahama and Isluga, with Tua, Olca, and Ollagua farther south, are constantly smoking.

These mountain systems divide Bolivia into a high region, containing many very elevated plains stretching between the enclosing heights of the west, and a low land forming the eastern side of the country, beneath the mountains, and at a comparatively small elevation above the sea. The high plains or basins of the plateau enclose a continental water system, from which there is no outlet to the ocean, the rivers terminating in lakes, of which Lake Titicaca is the chief, or in swamps, or in vast dried up salt fields,—rapid evaporation disposing of and balancing the supply of water flowing to these by the mountain streams.

Lakes. The valley or plateau which is occupied by the Lake of Titicaca and the Rio Desaguadero forms the most elevated table-land in the globe, with the exception of that of Thibet, which presents only mountain pastures, covered with sheep; while this table-land of the New World presents towns and populous cities, affords support to numerous herds of cattle, *llamas*, *guanacos*, and sheep, and is covered with harvests of maize, rye, barley, and wheat, at an elevation which has nothing to equal it in any other part of the world. The Lake of Titicaca or Chuquito, which occupies its northern extremity, is 12,600 feet above the level of the sea, and its extent is equal to fourteen times that of the Lake of Geneva, or 3220 square miles, the greatest depth being upwards of 700 feet. It is surrounded by numerous towns and villages, and a rich and fertile country, and contains several islands, the largest of which is called Titicaca, and was long held in great veneration by the Peruvian Indians, in consequence of its having been the place whence Manco Capac and his consort Manco Oello Huaco, the great founders of the empire of the Incas, issued, to spread civilization, industry, and good government among the surrounding nations. The Lake of Titicaca is very irregular in its form. It admits of extensive navigation for small vessels, though not unattended with danger, as it is subject to sudden storms and violent gusts of wind from the neighbouring mountains. This lake communicates with the smaller Lake of Pansa, or of the "Pampa Aullagas," situated at the southern extremity of the valley, by means of the Rio Desaguadero, which flows out of the Lake of Titicaca, and has a breadth of from 80 to 100 yards. This river and lake form part of the western boundaries between the Republics of Bolivia and Peru. Over the river was formed, in the time of the Incas, a suspension bridge, composed of cables and cords made of the grass and rushes which grow on its borders; and the work was constantly renewed from time to time, to obviate the effects of decay, as it constituted the only line of communication between the opposite sides of the valley. These lakes, with the Desaguadero, form the only receptacles for the water of those rivers and streams which descend from the surrounding mountains and enter this extensive plain, which has no visible outlet whereby its contents can escape otherwise than by evaporation.

Those rivers which take their rise from the western declivity of the Andes, and flow into the Pacific, are so inconsiderable in magnitude, and so short in their course, as scarcely to merit observation, and are only useful in supplying the means of a partial irrigation to the arid plains which separate these mountains from the Pacific. But those numerous rivers taking their origin on the eastern declivity of the Cordillera Real, which is the main waterparting of Bolivia, present a very different aspect, and are of much greater importance, since they communicate with large navigable rivers, which terminate in the Atlantic Ocean. Rivers.

rivers flowing to the great mediterranean navigation system of the Amazons in the north, or to the Rio de la Plata. More than forty years ago the importance of opening up a river highway from eastern Bolivia to the Rio Paraguay had impressed itself strongly on the Government, and large grants and privileges were offered in encouragement of this object, the rivers Otuquis, Tucabaca, and Latirequiqui, flowing to the Paraguay about the 20th parallel, being looked to as probably affording the desired navigable way. As yet, however, though this plan has been frequently revived, no definite progress has been made in this direction. An expedition sent down the Rio Pilcomayo in 1844 reported it innavigable. On the side of the Amazons, the rapids of the River Madeira, 18 in number, and extending over a distance of 230 miles, form a great natural barrier; to overcome this and to connect the navigable upper tributaries in Bolivia with the navigation of the lower Madeira, a company was recently formed for the construction of a railroad along the interrupted portion of the course of the Madeira: this scheme also is for the present in abeyance. It seems probable, however, that the recent opening of regular navigation on the Rio Vermejo from the Paraguay to the upper Argentine province of Jujuy on the southern frontier of Bolivia may to some extent afford an outlet, and tend to develop the resources of that part of the country.

Climate and vegetation.

Bolivia lies, as has been noticed, for the most part within the tropical zone; but from its peculiar formation, its climate and productions are dependent rather upon the elevation of different parts of the land than upon its geographical situation. In descending from the highest region of snow and ice to the low plains of rich tropical vegetation several zones or stages are distinguished. The name *Puna brava* is given to the uppermost mountain regions which rise above 12,500 feet to the snow limit: these are scarcely inhabited by man, and are characterized by mosses and hardier grasses,—the animal kingdom being represented by the vicuña, guanaco, llama, alpaca, viscacha, chinchilla, besides the condor and other birds of prey. The region between an elevation of 11,000 feet and the lower Puna brava is termed the *Puna*; less cold than the former, it is suited for the growth of potatoes, barley, and rush-like grasses, upon which sheep, llamas, vicuñas, &c., may feed. This division embraces the whole of the high plains of Bolivia, which are but scantily peopled or cultivated. Several species of cactus are found in these elevated regions, and especially the *Cactus peruvianus*, which sometimes grows to a height of from 20 to 30 or even 40 feet, and is serviceable for many purposes. Under the general name *Cabezera de Valle* are grouped the heads of the valleys descending to the lower lands, between 9500 and 11,000 feet in elevation, where the climate is temperate. These cultivable districts produce wheat, maize, and the ordinary vegetables. The *Valle* or *Medio Yunga* is the general name of the deeper portions of the valleys, between 9500 and 5000 feet, with warm climate, affording field and garden fruits in abundance. The *Yunga*, lastly, is the low tropical region, comprising all beneath 5000 feet, and producing all kinds of tropical fruits and vegetation.

In the punas the air is always dry and perceptibly cold, though the temperature may rise high in the sun, and cold, cutting blasts of air from the mountains are of frequent occurrence. In the Valle and upper Yunga a perpetual spring seems to reign, and night frosts are rare. The western side of the Andes is completely rainless, all moisture-bearing clouds rolling up from the ocean being quickly evaporated, or condensed in the higher mountain regions in snow or hail; but the whole of the remaining eastern region of Bolivia has a rainfall. In the lowlands this is irregular in season; but in the upper regions of the Puna and the Cabezera de Valle, a rainy season generally begins in the middle of November and concludes in the beginning of March, often accompanied by furious thunderstorms, with hail and snow in the higher regions. The climate of Potosi, at an elevation of 13,300 to 13,600 feet, is so various that in one day it frequently exhibits the vicissitudes of the four seasons of the year. Thus, during the night and the early part of the morning it is piercingly cold; in the forenoon it resembles our fine weather in March; in the afternoon the rays of the sun in so pure and attenuated an atmosphere are very powerful and scorchingly hot; while towards evening the air usually becomes mild and serene. Strangers on first arriving in these higher plains are usually affected with difficulty of breathing, owing to the extreme rarity of the atmosphere; they are likewise sufferers from dysentery, which, however, for the most part soon disappears, and in general the highlands are by no means unhealthy. Travellers in the higher regions are exposed to great danger and hardships owing to the storms which occasionally prevail, especially snow storms, which frequently produce the *surumpi*, or snow blindness, an affection which has proved fatal to some travellers. An infectious fever called "fiebre amarilla" sometimes breaks out in the Indian villages of the Puna, causing great loss of life; coughs and lung diseases are prevalent among the children in the punas, and do much injury among grown people in the Valle and Yungas. In descending through the eastern provinces towards the plains of Mojos and Chiquitos, all the gradations of climate are experienced down to that which characterizes the equinoctial regions of America, where intermittent "*terciana*" or cold fevers, dysenteries, and other diseases peculiar to warm climates prevail.

Anima[ls]

The animals which distinguish the more elevated parts of Bolivia are the *guanaco*, the *llama*, the *alpaca* (the first supposed to be the original from which the second and third varieties have been domesticated), and the *vicuña*. These animals, in their structure and habits, are all closely allied to the camel of Africa. Thus, an examination of the structure of the stomach shows that they are capable of existing during a considerable time without any supply of water, and in fact they are seldom seen to drink from the streams of their native mountains. The camel seems peculiarly well calculated to live in the arid and burning deserts of the Old World, and the form of its feet is singularly adapted for traversing rapidly these extensive plains; whilst, on the other hand, the guanaco and the llama have their feet so constructed as to enable them with facility to ascend and descend the abrupt declivities, and to traverse the rugged and uneven passes which abound in these mountains. They seem likewise to frequent particularly those parts of the Cordillera of the Andes which are the most dry and arid, and which are least clothed with forests and shrubbery. Thus, in the Cordillera which separates the Argentine Republic from Chili, the guanacos are found in great numbers on the summits and eastern declivities, which are exceedingly arid and bare when compared with the western or Chili side, where the Andes in their whole extent are clothed to a certain elevation with a broad belt of forest trees and evergreens, and where, at certain seasons of the year, there are heavy and continued rains. On this side guanacos are of comparatively rare occurrence. Their flesh is savoury when young, but not very palatable when full grown; their wool, however, is very valuable to the Indians, who manufacture it into hats and various kinds of woollen stuffs; and their skins, when tanned, are useful in making shoes and harness. The number of these animals in the country is estimated at not less than three millions; about a third part of them, the full-grown males, are employed as

beasts of burden, all the traffic of Bolivia being carried on by means of them.

The vicuña (*Camelus vicugna*) is a smaller animal than the guanaco or the llama, and only useful for its fleece. The wool is long and fine, and forms a valuable article of commerce; it is of a brownish colour, somewhat resembling that of a dried rose leaf; it has a soft, silky, and close texture, and is well adapted for the manufacture of hats and warm clothing. The vicuña very much resembles the llama and guanaco in its habits and dispositions, but cannot be usefully employed as a beast of burden. It usually frequents the highest parts of the mountains, is extremely timid, is gregarious, and runs very swiftly. The chinchilla (*Chinchilla lanigera*) is also an inhabitant of the mountainous parts of Bolivia. The skins, however, are of an inferior quality, although larger than those obtained from the northern parts of Chili; but still they form a very valuable article of commerce, on account of the great fineness and delicacy of their furs.

The sheep pasturing in the highlands of Bolivia are supposed to number about seven millions, and in the lower regions of the east horned cattle are very numerous. The eastern or more thickly-wooded parts of Bolivia are inhabited by a variety of wild animals, such as the jaguar and the tapir, which are more or less common in Brazil and the other parts of intertropical America of inconsiderable elevation.

Geology. The geological structure of the colossal mountains situated in Bolivia has hitherto been very imperfectly examined. We learn from Humboldt, however, that the metalliferous mountains near Potosi are principally composed of trachytic porphyries; and Mr Pentland discovered trachyte also in the mountain of Pichu, one of the most elevated of the western Cordillera. In the same chain there likewise exist various volcanic mountains, some of which are in an active state. There is perhaps no part of the world which affords a more interesting field for the investigations of the geologist than Bolivia, not only on account of the great elevation which it attains, but also from the exhibitions of internal structure presented by volcanic agency and otherwise,—not to mention the aid afforded by such inquiries in the prosecution of mining enterprises.

Minerals. The great variety, extent, and value of the mineral productions of the mountainous districts of Bolivia have given to this part of America an importance and celebrity which it would not otherwise have obtained, and have caused large and populous cities and towns to be built at elevations where the rigours of the climate and the deficient vegetation would otherwise have afforded very few inducements for fixing the abodes of industry. Mining is, however, at the present time in a ruinous state.

Gold is found in considerable quantities in the mountainous parts of Bolivia; but, owing to the expense of extracting the metal from the ore, the mines which produce it have not been worked to the extent of which they are capable. In these it is usually found in the form of grains or nodules, or intermixed with antimony, silver, and other substances, and is separated by reducing the whole to a fine powder, and by amalgamation with quicksilver. The mountain of Illimani is believed to contain great quantities of gold, in consequence of that metal having been found in a native state in considerable quantities in the lake of Illimani, situated at its base. In the 17th century, likewise, an Indian found here, at a short distance from the city of La Paz, a mass of native gold, which was said to have been detached from the mountain by the agency of lightning, and which, having been purchased for the sum of 11,269 dollars, was afterwards deposited in the cabinet of natural history at Madrid. But by far the greater part of the gold procured in Bolivia is obtained by means of the *lavaderos* or gold-washings, in the beds of rivulets, where it is found in the form of grains. The most productive of these are the celebrated lavaderos of Tipuani, consisting of streams descending from the snow-capped summits of the Cordillera of Ancuma, situated about sixty leagues to the north-east of the city of La Paz, in the province of Larecaja. The gold is found in the form of grains or *pepitas*, at the depth of 10 or 12 yards below the surface, embedded in a stratum of clay of several feet in thickness. The gold-washings at Tipuani were worked in the time of the Peruvian Incas, as is evinced by their tools, which are occasionally found embedded in the alluvial soil, and almost invariably in such situations as prove the most productive. The gold-washings and quartz veins of Choquecamata, in the province of Ayopaya in Cochabamba, are also famous, and their yield up to 1847 was valued at £8,000,000. Several districts of the departments of Potosi, Chuquisaca, Santa Cruz, and Tarija, are also rich in gold, but the greater part of the mines formerly worked have now been abandoned, or the known veins have not been explored.

Silver. Silver, however, has hitherto been the staple metallic production of Bolivia, and has given to it that celebrity which it has long possessed. In the rich mountains of Potosi alone, according to the records kept at Potosi of the *quintas* or royal duties from the year 1545 to the year 1800, no less than 823,950,509 dollars were coined during that period; and if the other produce of the mines be taken into account, it is estimated that not less than 1,647,901,018 dollars must have been obtained from this source alone during those 255 years.

The Cerro de Potosi, or argentiferous mountain of Potosi, has a somewhat conical form, resembling a colossal sugar-loaf; its base being about three leagues in circumference, and its summit 15,977 feet above the level of the sea, and 2697 above the level of the great square or *plaza* of the city of Potosi, which is situated at its base. At the foot of the Cerro is a smaller mountain called Huayna Potosi, or the Younger Potosi, likewise containing silver, but in less abundance than the other, and less accessible, from the numerous springs which there impede the operations of mining. The principal mountain has been worked as high up as within 125 feet of its summit. The labours of the miners have been principally confined to the upper half of the mountain, which has been perforated by numerous excavations, with at least 5000 openings of mines, the greater number of which are however abandoned. The upper part of the mountain is exhausted to a considerable extent of its valuable contents; but the lower part is still in a great measure untouched, as the springs are there more numerous, and the water accumulates in such quantities as materially to interrupt the further progress of the miners. The mines of Potosi, according to Humboldt, rank next in importance to those of Guanaxuato in Mexico. The existence of silver in this place was first accidentally discovered by an Indian in the year 1545, and ever since that time its mines have been worked. In 1858, twenty-two companies were working 46 silver mines and 4 tin shafts in the province of Potosi, and the yield in 1856 amounted to a value of nearly a million dollars.

are now abandoned; and those of the province of Arque in Cochabamba are not now regularly worked. The rich silver mines of Lípez also lie fallow, as do those of the department of Oruro. In 1870 great silver deposits were discovered at Caracoles, about 120 miles inland, in the desert province of Atacama, drawing thither a rush of miners from all parts of Chili and Peru.

Among the other mineral riches of Bolivia copper takes the next rank, and is also widely distributed. The province of Ingavi in La Paz possesses mines from which 15,000 to 20,000 cwts. of copper are annually taken. The departments of Potosí, Chuquisaca, Oruro, and Atacama are also rich in copper. Tin is mined to some extent in Potosí and Oruro, where it is found along with the silver. Lead is also frequently found in the neighbourhood of silver, as well as quicksilver. The methods hitherto employed for the reduction of the ores of this country are exceedingly imperfect and inefficient. More skill and capital are requisite to render them productive and remunerating. Coal and iron have been found in the departments of Chuquisaca, Oruro, and Beni, though the extent or value of these products is yet unknown. Precious stones, chiefly the hyacinth and opal, have been found in the department of Santa Cruz, and diamonds in Beni.

Very valuable beds of guano extend along the Pacific coast between 23° and 25° S., those of Mexillones being specially famous. Nitrate of soda also exists in great quantity in the deserts of Atacama, and is profitably worked.

The roads which form the means of communication between Bolivia and the surrounding countries, and between the various provinces of the republic, are in no respect sufficient for the important purposes which they are destined to serve. By inattention to the formation and preservation of roads, the Spaniards and their descendants have fallen greatly behind the ancient Peruvians, whose industry and civilization they affected to despise, and laboured hard to depreciate. The present route, for it can scarcely be designated by the name of road, from Potosí to Jujuy, the first city belonging to the Argentine Republic, is about 310 miles in length; and this place forms the point where a road commences for carriages and waggons as far as Buenos Ayres, an additional extent of land carriage of about 1617 geographical miles. The various routes from Bolivia to the coast of the Pacific, by the way of Cobija, by Tarapaca, and by Oruro to Tacna, can only be passed on mules or horseback; and travellers are sometimes exposed to great perils and hardships from exposure to the storms which occasionally prevail at such great elevations. The President Ballivian, however, while in office, did much to obviate these difficulties, and initiated a new era of things by the construction of a splendid highway, which leads from Sucre, and passing Santa Cruz, connects Mojos and Chiquitos and the fertile plains of the Beni and Madeira.
Although railroads are as yet unknown in the greater part
for Bolivia, and though the country presents the most
a begidable natural difficulties in the way of engineering,
line atning has been made in this direction. The only

The productions furnished by Bolivia as articles of commerce are chiefly the precious metals, vicuña and alpaca wool, guano, nitrate of soda, leather, coffee, cacao, and chinchona bark; but from the fact that no direct commercial intercourse has ever existed with the outer world, these products are frequently ascribed to the countries through which they must pass. Thus the metals and wools of Bolivia are looked upon as Peruvian, and the cinchona bark and gums passing out eastward are credited to Brazil or the Argentine Republic. The rude and simple fabrics manufactured by the Peruvian Indians are usually appropriated to their own domestic uses; while the valuable vegetable productions, and the herds of cattle and mules which are reared in the eastern parts of the republic, have hitherto scarcely been sufficient for the supply of the inhabitants of those populous mining districts that are principally dependent on them for subsistence. Products and trade

Before the war of independence a very extensive traffic was maintained between the upper provinces of Peru (or Bolivia) and the provinces of the Rio de la Plata for supplies of cattle and mules. These were reared in great numbers in all the interior Argentine provinces expressly for the use of those countries, and were first sent by easy journeys to the luxuriant pastures of Salta and Jujuy, where they were carefully fed and tended during the winter, previous to their being conveyed to their final destination in Bolivia and Peru. Some idea may be formed of the extent of this traffic from the statement that, besides all those furnished by the other Argentine provinces, the province of Salta alone supplied annually to Upper and Lower Peru from 60,000 to 80,000 mules, on all of which they realized considerable profits, the prices being proportioned to the distance to which they were conveyed. The customs derived from the import of cattle from the Argentine Republic still form an important source of revenue. The trade is now in a great degree diverted from the Argentine provinces to the ports of the Pacific called the Puertos Intermedios. Tacna and Arequipa, with their respective ports, have now become the principal channels through which Bolivia receives the produce and manufactures of other countries, the Bolivian port of Cobija being of little value, owing to the difficulties of transport from it by mules and llamas across the desert track and the mountains. There are no certain returns of the value of the trade of Bolivia; the importation by Tacna and Arica is valued at 5 or 6 millions of dollars, that of Cobija at $1\frac{1}{2}$ to 2 millions. A new and very important channel of communication for commerce will be opened between Bolivia and the Atlantic, whenever commercial enterprise and increasing civilization shall have established steam navigation on the Rio de la Plata and its tributary streams, or from the mouth of the Amazons to its distant tributaries the Beni and the Mamore.

The population of Bolivia consists of a mixture of various races, chiefly of the Spaniards with the Indian natives. A third of their number live in towns or "villas," the rest in smaller villages, or in the open camp. Besides the native Indians there are in the country some descendants of African negro slaves, and not a few Guaranis, who came over from the regions east of the Paraguay, and settling in the plains, have increased in numbers. The Indian population may be considered as the civilized, the half civilized, and the wild. To the first class belong the Quichua and Aymara, or the Inca Indians, who are by far the most numerous, who have come most closely into contact with the Spanish invaders, and who occupy chiefly the highlands of the west. The Indians of Mojos and Chiquitos may be considered as representing the half-civilized class,—retaining part of the civilization introduced among them in the 17th century by the Jesuits. The nomadic or wild Indians of the eastern lowlands in Population.

Bolivia belong to the following tribes:—The *Sirionos*, who inhabit the banks of the Rio Grande or Guapay, and of the Rio Pirai; the *Hichilos*, who occupy the pampas north of San Carlos in the department of Beni; the *Penoquiquias*, living in the upper or southern districts of the River Itonama or San Miguel; the *Guarañocas*, inhabiting the western portion of the space between the rivers Tucabaca and Latiriquique; the *Potororos* in the north-west of the same district; and the *Chiriguanos*, occupying the country along the north of the upper Pilcomayo below the confluence of the Pilaya. To these may be added the *Tobas*, who though they generally occupy the lower basin of the Rio Vermejo in the Argentine portion of the Chaco, occasionally make raids into the departments of Tarija and Chuquisaca, plundering and destroying the villages, and carrying off women and cattle. The Quichua and Aymara have no relations or sympathies with the Indians of the plains, who in their turn hold the civilized Indians in great contempt. These descendants of the Peruvians under the empire of the Incas are still numerous, notwithstanding the many causes which have tended to diminish their numbers, and form a distinct race, preserving the language and manners of their ancestors, their habits having been only somewhat modified by the circumstances in which they have been placed since they came under the dominion of the Spaniards. The Quichuas are mild in character, apparently subdued and apathetic,—qualities which are but the natural result of the state of subjection and debasement in which they were long held by their conquerors; they are, however, robust and muscular, and capable of great endurance, though little inclined to labour; their customs are rude and simple, their mode of living poor in the extreme. The Aymara are perhaps more mobile in character, but in other respects similar. Both are cultivators of the land according to their rude notions of husbandry; vegetables, especially maize and potatoes, form the staple of their food, and they indulge freely in their favourite *chicha*, an intoxicating liquor prepared from maize; many are employed as drivers of llama trains, or are breeders of the llama, sheep, or goats, which they possess in great numbers. Among the half-bred population of Bolivia, who stand in relation of numbers to the Inca Indians as about one to two, there are distinguished the *zambo*, or half-negro half-Indian, powerful in frame and intelligent, but unfaithful and cunning; the *mulatto*, or offspring of the Spaniard and negro; and the *cholo*, the descendant of the alliances of the Spaniards with the Inca Indians. The last generally resemble their fathers in character, and occupy themselves chiefly in mining. It is to the Cholos that Bolivia owes its political independence.

The population of Bolivia has greatly increased since the year of independence, 1825, when the whole number did not exceed 979,000; in 1831 it exceeded 1,000,000; at the census of 1846 it had risen to 1,380,000. The following table shows the population of each department, as given by Ondarza in 1858. This is the most recent detailed statement of the population of Bolivia, but an estimate of the population of the ecclesiastical divisions of the country for 1874 is appended to it; the provinces into which each department is divided are also named, on the authority of Herr Reck:—

Departments.	Provinces.	Population, 1858.
La Paz	La Paz, Omasuyos, Ingavi, Sicasica, Muñecas, Yungas, Larecaja, Inquisivi	475,322
	Carry forward,	475,322
	Brought forward,	475,322
Cochabamba	Cochabamba, Cliza, Tapacarí, Mizque, Arque, Ayopaya	349,892
Potosi	Potosí, Porco, Chayanta, Chichas, Lipez	281,229
Chuquisaca	Yamparaes, Tomina-azero, Cinti	223,668
Santa Cruz de la Sierra.	Santa Cruz, Valle Grande, Chiquitos, Cordillera	153,164
Oruro	Oruro, París or Poópo, Carangas	110,931
Tarija	Tarija, Salinas, Concepcion	88,900
Beni	Mojos, Caupolican or Apolobamba, Juracarés	53,973
Atacama ...	Upper and Lower Deserts	5,273
		1,742,352
	Wild Indians	245,000
	Total..............	1,987,352

The *Archbishopric of La Plata*, including the departments of Potosí, Chuquisaca, Oruro, Tarija, and Atacama, contained in 1874 706,989 inhabitants; the *Bishopric of La Paz*, the department of La Paz, 519,465; the *Bishopric of Santa Cruz*, the department of Santa Cruz, 205,131; and the *Bishopric of Cochabamba*, the department of Cochabamba, 379,783,—total, 1,811,368. Decrees of 1866 and 1867 ordered the formation of two new departments, viz., *Melgarejo*, to be formed of part of the existing department of Cochabamba, and including the town of Tarata, and *Mexillones*, on the coast.

The populations of the chief towns, in 1858, were as follows:—La Paz, 76,372; Cochabamba, 40,678; Chuquisaca or Sucre, 23,979; Potosí, 22,580; Santa Cruz, 9780; Oruro (the seat of Government since 1869), 7980; Tarija, 5680; Trinidad, 4170; Cobija, 2380. Among the small number of foreigners in the country, Italians, Spaniards, and French are in a majority.

Area. The area of Bolivia, hitherto very uncertain, on account of the indefinite state of the frontier on the east and south, has been calculated at Gotha, on the basis of the recent determination of the boundary with Brazil, at 536,200 English square miles, or about ten times the extent of England.

The constitution given to the country by Bolivar, which, in the frequent revolutions of later times has often been modified and altered, and sometimes set aside altogether, is founded on the strictest principles of justice, in as far as regards the civil rights and privileges of the community; but in other respects, and particularly in reference to the supreme executive authority, its provisions savour strongly of a monarchical spirit. The supreme authority is vested in a *presidente vitalicio*, or president for life, with the power of naming his successor. It guarantees to the Bolivians civil liberty, security of persons and property, and equality of rights; the free exercise and communication of thoughts and opinions, either by the press or otherwise; liberty to remain or leave the territory of the republic with their property, at their pleasure, but without prejudice to others; equality in the imposition of taxes and contributions, from the payment of which none can be exempted; and the abolition of all hereditary employments, privileges, and entails. No profession, trade, or employment can be prohibited, unless repugnant to public feeling, or injurious to the health and security of the community; and every inventor is secured in the benefits of his discovery. No one can be arrested without previous information of the alleged fact of delinquency, unless when taken *flagranti delicto*. All trials and judgments are public; and in criminal cases none can be imprisoned more than forty-eight hours without having presented to him the charges preferred against him, and being delivered over to the proper tribunal or judge.

Government.

By this constitution all legitimate power emanates directly from the people, and is in the first instance exercised by all who can justly claim the privilege of citizens. Of these every ten nominate an elector, who exercises his delegated authority for a period of four years. At the commencement of each year all the electors assemble in the capitals of their respective provinces, and regulate their proceedings and the exercise of their various functions by a plurality of votes. They elect the members of the three legislative chambers, the number of each amounting to thirty; those for the chamber of tribunes being nominated for four years, and renewed by moieties every two years; those for the senate for eight years, and renewed by moieties every four years; and those for the chamber of censors being nominated for life.

The executive government consists of a president, vice-president, and three secretaries of state. The president of the republic is named for the first time by a majority of the collective legislature, and retains the dignity during life, with the power of naming his successor. He is the chief of the administration of the state, and is not responsible for the acts of his administration. The constitutional privileges of the president are the most limited that have been intrusted to the supreme chief of any nation. They extend only to the nomination of the officers of the revenue, of peace, and of war, and the command of the army. The administration belongs wholly to the ministry, which is responsible to the senate, and is subject to the jealous vigilance of the legislators, magistrates, judges, and citizens. The judicial department enjoys the most perfect independence, the members composing it being proposed by the people, and chosen by the legislature. Slavery in every form has long been abolished, and the exercise of religion is free from all restraints. The armed force is composed of the regular army, amounting to about 3000 officers and men, to garrison and defend the frontiers; of the national militia to preserve internal order; of the preventive service to protect the revenue; and of a navy when circumstances may require its formation.

Revenue.

The financial budget of Bolivia for 1873–74 was as follows, the amount being given in Bolivian dollars of the value of about 3s. 3d. sterling:—

RECEIPTS—

Customs { Arica	405,000
Customs { Cobija	250,000
Export of Silver	193,676
Sale of Guano	300,000
Stamps	27,628
Cattle Customs (Argentine Republic)	20,880
English Loan	650,000
Indian Tribute	686,307
Departments	396,423
	2,929,914

EXPENDITURE....4,505,504

Public debt 1873 = 16,428,329 bolivianos, including £1,700,000 sterling of the loan for railways.

The early history of that part of the empire of the Incas which now forms the Republic of Bolivia is so intimately connected with that of Peru, that the consideration of it may with propriety be deferred until we come to treat of that country, in which Cuzco, the capital of the Incas, is situated. Attention will therefore at present be directed chiefly to that period of its history which is more recent, and which has so materially influenced its present condition.

The Peruvians, ever since the conquest of their country by the Spaniards in the 16th century, have been subjected to a system of tyranny and oppression which has few parallels in the history of the universe. They were treated little better than beasts of burden. By their toil the gold and silver were obtained from the mines, the lands were cultivated, the flocks and herds were attended to, and all the domestic and menial offices performed. Yet the fruits of their labour, especially that of mining, which was attended with numerous privations, and often with great loss of life, were altogether devoted to enriching their oppressors.

One of their principal grievances was the *mita*, a compulsory kind of personal labour, either in the working of the mines or in the cultivation of the fields, exacted from the Indians generally for the space of one year. The proprietors of mines and land to be worked or cultivated were privileged to claim as their undoubted right the personal services of the Indian population of the district surrounding that in which their property was situated. By the regulations of the *mita* a proportional number of the Indians of the district were annually chosen by lot for the purposes required; and some idea may be formed of the effects of such a regulation from the fact that 1400 mines were registered in Peru alone, and that every mine which remained unworked a year and a day became the property of the first claimant. So much was the labour of the mines dreaded by those persons on whom the lot fell, that they considered it as equivalent to a sentence of death, and made all their arrangements accordingly, carrying with them their wives and families to their new and dreaded place of abode. An estimate may be formed of the extent of this evil from 12,000 Indians having been annually required by the *mita* of Potosi alone; and it is calculated that, in the mines of Peru, no less than 8,285,000 Indians have perished in this manner. Besides the *mita* for the service of the mines, the Indians were also compelled to labour for their superiors on their cultivated estates, their *estancias* or grazing farms, and also in their *obrages* or manufactories.

The tribute exacted by the Government from every Indian between the age of eighteen and fifty-five was a capitation tax of 8 dollars. This was levied with the greatest rigour, and the official persons charged with its collection frequently committed great injustice in doing so,—obliging the Indians to commence these payments at fifteen, and continue them until seventy years of age, and putting the amount of tribute for the years before and after the legal period into their own pockets. In proof of

the extent to which this evil was carried, and of the rapacity of the Spanish Government, it may be stated that a law was enacted for the express purpose of augmenting the number of the people liable to pay tribute. By it the Indians were obliged to marry, the men at the age of fifteen, the women at thirteen. The governor of each province was responsible to the Government for the amount of the tribute, which was regulated by a census of the tributary Indians, taken every seven years; and in this many frauds were practised, the actual number being often underrated.

Besides all these, the Peruvian Indians were long subjected to another system of extortion no less grievous and unjust,—the law of *repartamiento.* This was originally established with the best intentions,—the governors or *corregidors* of the districts being intrusted with the charge of supplying the inhabitants under their care with such articles as they might require at a fair and equitable price. But the law, which had so plausible an origin, was shamefully abused; and it was made compulsory on the Indian population to purchase worthless articles at an extravagant price.

The constant and extensive operation of these demoralizing practices, although more immediately affecting the aboriginal population, could not fail to produce the most pernicious effects on the Creoles or descendants of the Spaniards; but, in addition to these causes of debasement, the latter were subjected to numerous unjust and oppressive laws, all tending to paralyze their advancement.

The raising of those vegetable products which form the principal objects of culture in Spain, as articles of commerce, was strictly prohibited to the South Americans, however favourable the soil and climate of their native country might be for the production of them. No kind of manufacture of cloth or articles of clothing was permitted which could interfere with the commerce of Old Spain, excepting only the coarse fabrics manufactured and worn by the Indians. Even the valuable mines of mercury and iron found in South America were, in a great measure, hermetically sealed by prohibitory decrees, lest they might interfere with the traffic carried on by Spain in these articles. And, not only was the commerce of South America confined entirely to Spain and prohibited with other nations, under the severest penalties, but the colonies were not permitted to have any commerce with each other.

The grievances under which they suffered at length exceeded even the powers of endurance possessed by the pacific Indians, and gave rise to the insurrection of 1780–81, led by the Inca Tupac Amarú, who spread fire and sword against everything Spanish from Cuzco to Jujuy; twice the city of La Paz was besieged by a force of 20,000 Indians; and in the battle before that town Tupac Amarú was made prisoner and put to death in the most barbarous manner by the Spaniards. The insurrection was finally put down in 1782, and with it ended the last power of the Incas. The aboriginal population, having failed in their arduous undertaking, after the destruction of great numbers of their nation, and finding their chains now rivetted with double force, never again recovered their wonted energies. This accounts for the comparative indifference with which they viewed the rise and progress of the war of independence.

From the causes already stated, the war of independence was principally carried on, as regards Bolivia, by the resources of, and in concert with, the neighbouring provinces of the Rio de la Plata and Peru, all of which had equal cause to avenge themselves on their oppressors, but were placed in circumstances somewhat more fortunate for accomplishing their purpose. When the patriots of Buenos Ayres had succeeded in liberating from the dominion of Spain the interior provinces of the Rio de la Plata, they turned their arms against their enemies who held Upper Peru. An almost uninterrupted warfare followed, from July 1809 till August 1825, with alternate successes on the side of the Spanish or royalist and the South American or patriot forces,—the scene of action lying chiefly between the Argentine provinces of Salta and Jujuy and the shores of Lake Titicaca. The first movement of the war was the successful invasion of Upper Peru by the army of Buenos Ayres, under General Balcarce, which, after twice defeating the Spanish troops, was able to celebrate the first anniversary of independence near Lake Titicaca, in May 1811. Soon, however, the patriot army, owing to the dissolute conduct and negligence of its leaders, became disorganized, and was attacked and defeated, in June 1811, by the Spanish army under General Goyeneche, and driven back into Jujuy. Four years of warfare, in which victory was alternately with the Spaniards and the patriots, was terminated in 1815 by the total rout of the latter in a battle which took place between Potosi and Oruro. To this succeeded a revolt of the Indians of the southern provinces of Peru, and the object being the independence of the whole country, it was joined by numerous Creoles. This insurrection was, however, speedily put down by the royalists. In 1816 the Spanish general Laserna, having been appointed commander-in-chief of Upper Peru, made an attempt to invade the Argentine provinces, intending to march on Buenos Ayres, but he was completely foiled in this by the activity of the irregular *gaucho* troops of Salta and Jujuy, and was forced to retire. During this time and in the six succeeding years a guerilla warfare was maintained by the patriots of Upper Peru, who had taken refuge in the mountains, chiefly of the province of Yungas, and who frequently harassed the royalist troops. In June 1823 the expedition of General Santa Cruz, prepared with great zeal and activity at Lima, marched in two divisions upon Upper Peru, and in the following months of July and August the whole country between La Paz and Oruro was occupied by his forces; but later, the indecision and want of judgment displayed by Santa Cruz allowed a retreat to be made before a smaller royalist army, and a severe storm converted their retreat into a precipitate flight, only a remnant of the expedition again reaching Lima. In 1824, after the great battle of Ayacucho in Lower Peru, General Sucre, whose valour had contributed so much to the patriot success of that day, marched with a part of the victorious army into Upper Peru. On the news of the victory a universal rising of the patriots took place, and before Sucre had reached Oruro and Puno, in February 1825, La Paz was already in their possession, and the royalist garrisons of several towns had gone over to their side. The Spanish general Olañeta, with a diminished army of 2000 men, was confined to the province of Potosi, where he held out till March 1825, when he was mortally wounded in an action with some of his own revolted troops.

was summoned and formally installed at Chuquisaca on the 25th May 1826, to take into consideration the constitution prepared by Bolivar for the new republic. A favourable report was made to that body by a committee appointed to examine it, on which it was approved by the congress, and declared to be the constitution of the republic; and as such, it was sworn to by the people. General Sucre was chosen president for life, according to the constitution, but only accepted the appointment for the space of two years, and on the express condition that 2000 Colombian troops should be permitted to remain with him.

The independence of the country, so dearly bought, did not, however, secure for it a peaceful future. Repeated risings occurred, till in the end of 1827 General Sucre and his Colombian troops were driven from La Paz. A new congress was formed at Chuquisaca in April 1828, which modified the constitution given by Bolivar, and chose Marshal Santa Cruz for president; but only a year later a revolution, led by General Blanco, threw the country into disorder and for a time overturned the Government. Quiet being again restored in 1831, Santa Cruz promulgated the code of laws which bore his name, and brought the financial affairs of the country into some order; he also concluded a treaty of commerce with Peru, and for several years Bolivia remained in peace. In 1835, when a struggle for the chief power had made two factions in the neighbouring republic of Peru, Santa Cruz was induced to take a part in the contest; he marched into that country, and after defeating General Gamarra, the leader of one of the opposing parties, completed the pacification of Peru in the spring of 1836, named himself its protector, and had in view a confederation of the two countries. At this juncture the Government of Chili interfered actively, and espousing the cause of Gamarra, sent troops into Peru. Three years of fighting ensued, till in a battle at Jungay in June 1839 Santa Cruz was defeated and exiled, Gamarra became president of Peru, and General Velasco provisional chief in Bolivia. The Santa Cruz party, however, remained strong in Bolivia, and soon revolted successfully against the new head of the Government, ultimately installing General Ballivian in the chief power. Taking advantage of the disturbed condition of Bolivia, Gamarra made an attempt to annex the rich province of La Paz, invading it in August 1841 and besieging the capital; but in a battle with Ballivian his army was totally routed, and Gamarra himself was killed. The Bolivian general was now in turn to invade Peru, when Chili again interfered to prevent him. Ballivian remained in the presidency till 1848, when he retired to Valparaiso, and in the end of that year General Belzu, after leading a successful military revolution, took the chief power, and during his presidency endeavoured to promote agriculture, industry, and trade. General Jorge Cordova succeeded him, but had not been long in office when a new revolt in September 1857, originating with the garrison of Oruro, spread over the land, and compelled him to quit the country. His place was taken by Dr José Maria Linares, the originator of the revolution, who taking into his own hands all the powers of Government, and acting with the greatest severity, caused himself to be proclaimed dictator in March 1858. Fresh disturbances led to the deposition of Linares in 1861, when Dr Maria de Acha was chosen president. In 1862 a treaty of peace and commerce with the United States of North America was ratified, and in the following year a similar treaty was concluded with Belgium; but new causes of disagreement with Chili had arisen in the discovery of rich beds of guano on the eastern coast-land of the desert of Atacama, which threatened warfare, and were only set at rest by the treaty of August 1866, in which the 24th parallel of latitude was adopted as the boundary between the two republics. A new military revolution, led by Maria Melgarejo, broke out in 1865, and in February of that year the troops of President Acha were defeated in a battle near Potosi, when Melgarejo took the dominion of the country. After defeating two revolutions, in 1865 and 1866, the new president declared a political amnesty, and in 1869, after imposing a revised constitution on the country, he became its dictator till 1871.

Such, in brief, are the rapidly succeeding political changes and internal conflicts which have kept Bolivia far behind its neighbouring republics, and have prevented the development of its natural wealth. Notwithstanding these wars and revolutions which rent the country, Bolivia had maintained itself without foreign credit until the presidency of Melgarejo, when it was drawn into disastrous speculations and contracts which have compromised its credit and loaded the country with a heavy foreign debt.

President Morales was elected in 1871; since that time a civilian Government has succeeded to the military system, and attempts are being made to reform the disordered affairs of the republic.

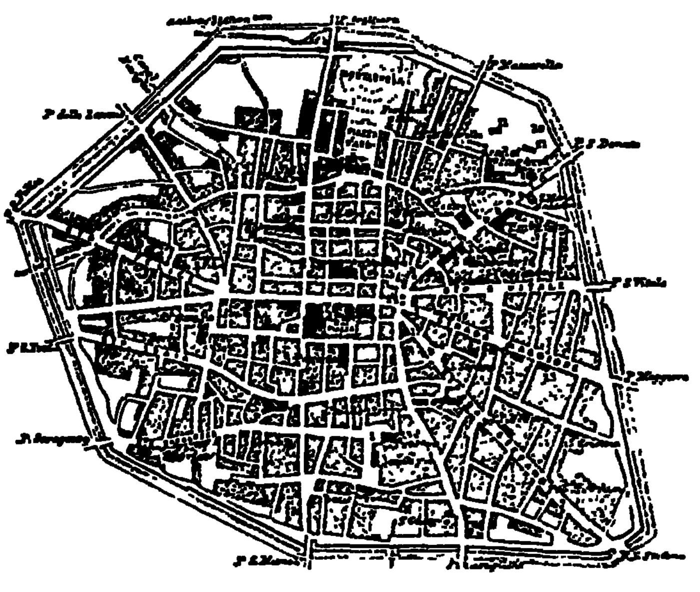
BOLLANDIST FATHERS, The, the authors of the famous *Acta Sanctorum*. During the Roman Catholic revival in the end of the 16th and beginning of the 17th centuries a great number of martyrologies were published, and it occurred to a Jesuit father, Heribert Rosweyd, to collect all the various legends about the martyrs and saints of the church into one great standard martyrology, which he proposed should fill 18 vols. folio. Rosweyd died in 1629 without having been able to carry out his plan. His idea, however, was taken up by John Bolland, a Jesuit father of the Low Countries, who had settled in Antwerp. He began an extensive correspondence, writing to every one throughout Europe who he supposed was able to help him. The public libraries and the libraries of convents and churches were thoroughly examined for MSS. about saints and martyrs, and so much material was found that the original plan of the work was soon widened. The ground-plan of the undertaking was to form a huge calendar, giving the life and deeds of each saint under the heading of the day set apart by the church for his honour. In 1643 the first two volumes were published, containing the saints' days in January. Bolland died soon after the beginning of his labour, but not until he had seen the work fairly started; other deaths followed, but the work was prosecuted in accordance with the original plan, and went on prosperously until 1773, when the troubles which then overtook the Jesuits affected the Bollandists also. The little company struggled on, however, amid many difficulties until 1794, when they were dispersed; and the whole of the MS. collections were destroyed during the French invasion of the Netherlands. At this time 54 vols. had been published, bringing the work down to the 15th of October.

In 1837 three Jesuit fathers made proposals to continue the *Acta* according to the original plan, and in 1838 published a programme under the title *De prosecutione operis Bollandiani.* They made some progress with the undertaking, but their work is much inferior to the earlier *Acta.* The 54 vols. of the older Bollandists, along with 6 vols. of the continuation, were published at Paris and Rome in 1863-7.

BOLOGNA, a province of northern Italy, having an area of 1385 square miles. It consists in the north of a fertile plain, well watered by several tributaries of the Po, while the southern portion is occupied by the Apennines, which separate it from Tuscany. It is in a highly flourishing condition. The soil produces abundant crops of rice, barley, wheat, and pulse, besides hemp, flax, olives, grapes, figs, almonds, chestnuts, and other fruits. The culture of silk is largely prosecuted; and considerable numbers of cattle and swine are reared in the province.

BOLOGNA, the chief city of the above province and the see of an archbishop, is situated between the rivers Reno (*Rhenus*) and Savena, at the foot of the lower slopes of the Apennines, 399 feet above the level of the Adriatic, and 23 miles S.E. of Modena, on the main line of railway that runs across the north of Italy, in 44° 30′ N. lat. and 11° 21′ E. long The city is about 2 miles in length and 1½ in breadth, and is surrounded by a high brick wall with



Ground-Plan of Bologna.

twelve gates. The streets are clean and well paved, but are generally narrow and crooked; the houses are mostly three stories high with projecting roofs, and are very often surrounded with arcades. All the public as well as private buildings are constructed of brick. The Piazza Vittorio Emmanuele, formerly called Piazza Maggiore or del Gigante, is the principal square and has many fine edifices. In the centre is a fountain adorned with a colossal statue of Neptune by Giovanni da Bologna. The city contains no fewer than 130 churches, twenty convents, and six hospitals. Of the churches the largest is San Petronio, an unfinished but splendid structure dating from 1390, and dedicated to the patron saint of the city. The cathedral or S. Pietro, begun in 1605, is surpassed not only by it but by S. Dominico, S. Giacomo Maggiore, and various others. San Stefano is a curious collection of seven churches, with a good deal of antiquarian interest. (*Vide* Street's *Brick and Marble in the Middle Ages*, 1874.) Of the secular buildings the most important are the Palazzo Pubblico, founded in 1290, the Palazzo del Podestà, of slightly earlier date, the Palazzo della Mercanzia, or Chamber of Commerce, and a few of the residences of the great mediæval families. At the head of the educational institutions stands the university, which was once the most celebrated in Italy, but is now attended by only 400 or 500 students. The university library, which was at one time in the keeping of Cardinal Mezzofanti, numbers upwards of 140,000 volumes and 9000 MSS. The Accademia delle Belle Arte, situated in what was formerly the Jesuit's College, has a rich gallery of paintings, chiefly by native artists. There is a museum of antiquities in connection with the university, as well as a botanical garden, and an observatory; and the city possesses besides a scientific institute, a philharmonic lyceum, and various intellectual institutions, many of which are due to the liberality of Count Ferdinand Marsigli, in the 17th century. There are five theatres (the Teatro del Commune, erected in 1756 by Bibiena, on the site of the Palazzo Bentivoglio, being one of the largest in Italy), a casino, and a hall for playing the favourite game of ball. The leaning towers of Asinelli and Garisende are worthy of mention. They are situated quite near each other; the former, which is 272 feet in height, deviates 5 feet from the perpendicular, while the latter has a height of 138 feet and a divergence of 9. Bologna has long been famous for its Mortadelle sausages, its soap, and a kind of confection called *terra catù;* its manufactures also include crape, silk, glass, wax candles, paper, and musical instruments. The people have a very peculiar dialect. The city is the birthplace of Domenichino, Guido Reni, the Carraccis, Righini, Benedict XIV., and other famous men, and gave rise and name to the Bolognese school of painting. Population in 1871, 115,957.

Bologna is said to have been founded by an Etruscan king, and was originally called Felsina after his name. It was held for some time by the Boian Gauls, and on their expulsion became, in 189 B.C., a Roman colony under the name of Bononia. Its importance rapidly increased, but it does not appear much in history till the time of the civil wars. The terms of the second triumvirate were settled in 43 B.C. in an interview held between Octavius Antony and Lepidus on a neighbouring island. During the later empire the city was frequently an imperial residence, and in 410 A.D. it was still strong enough to resist the forces of Alaric. It afterwards passed under the power of the Lombards, and on their subjugation by Charlemagne it was united to his empire and made a free imperial city. In 962 it became an independent republic, which soon acquired an extensive commerce and a powerful military force. The Middle Ages form the period of its greatest celebrity and importance. In the Crusades the Bolognese took an active share; and after a long neutrality in the contest between the Ghibellines

styled in Italy), a celebrated sculptor, was born at Douay in 1524, and died at Florence in 1608. He went early to Italy, and studied at Florence, where his best works still remain. His two most celebrated productions are the single bronze figure of Mercury, poised on one foot, resting on the head of a zephyr, as if in the act of springing into the air (in the Florentine gallery), and the famous marble group of the Rape of the Sabines, which received this name, Lanzi informs us, after it was finished. It is now in the Loggia de Lanzi of the ducal piazza. Giovanni was also employed at Genoa, where he executed various excellent works, chiefly in bronze. All his pieces are characterized by great spirit and elegance.

BOLSENA, a town of Italy, in the province of Rome, and the district of Viterbo, 10 miles S. by E. of Orvieto. It is situated on the north shore of the lake of the same name (*Lago di Bolsena*), and probably occupies the site of the Roman city of Volsinii. The principal remains are the ruins of an amphitheatre and those of a temple, which is popularly called *il Tempio di Norzia* after the Etruscan goddess Norsia, and there are numerous other relics scattered throughout the city or built into the walls of its modern buildings. Volsinii was originally one of the most powerful of the Etruscan cities, and occupied a position among the hills; but after a series of struggles with the Romans, the Volsinians were finally subdued about 280 B.C., their city was razed to the ground, and themselves obliged to settle in a less defensible site in the plain. The only event of interest in the history of the new town was its being the birthplace of Sejanus, the favourite of Tiberius. Its present population is only 2690. The Lake of Bolsena is about 10 miles in length by 8 in breadth, and is surrounded by well-wooded hills. It contains two small islands, Bisentina and Martana, in the latter of which Amalasontha, the wife of Theodatus, king of the Goths, was put to death by his orders.

BOLTON, or BOLTON LE MOORS, a municipal and parliamentary borough of England, in the county of Lancashire, 11 miles N.W. of Manchester, in 53° 35′ N. lat. and 2° 37′ W. long. It is divided by the Croal, a small tributary of the Irwell, into Great and Little Bolton, the former of which is situated on the south side of the stream. The town is on the whole well arranged and well built, and great improvements and extensions have been effected since 1860. An abundant supply of water is obtained from the neighbouring hills and stored in reservoirs at Belmont, Sharples, and Heaton. The waterworks, formerly in the hands of a company founded in 1824, have been the property of the corporation since 1847. The water rises by natural pressure to a height of 80 feet. Bolton possesses a large number of churches, but few are remarkable for either antiquity or architecture. The parish church of St Peter's, a building of somewhat early date, was rebuilt in an elaborate style about 1868. Among the educational establishments may be mentioned Lever's Grammar School, founded in 1641, where Dr Ainsworth, the Latin lexicographer, and Lemprière, of the *Classical Dictionary*, were formerly masters. A new town-hall, a market hall, a fish-market, an exchange, a theatre, and assembly rooms, are among the chief buildings. There are several public libraries and a mechanics' institute; and in 1855 a large Church of England institute was erected. During the great cotton famine the unemployed operatives were set to work on a large public park, which was opened in 1866. The cotton manufacture in various departments is still the most important in the town; in 1871 it gave employment to 8708 men and 11,353 women of twenty years of age and upwards. Various other industries, however, are extensively carried on. In 1871, 1030 adult workmen were employed in the manufacture of machinery, and 2524 in the iron manufacture; while silk-weaving was the occupation of 881, linen-weaving of 289, and paper-making of 306. Bleaching is also extensively carried on, and there are chemical works, dye-works, and calico-printing establishments. The coal mines in the neighbourhood give employment to nearly 4000 miners. Bolton is a place of some antiquity, but had little importance till the introduction of the woollen manufacture by Flemish immigrants about 1337. Several centuries afterwards its industries received a further development from a body of French refugees, driven from their own country by the Edict of Nantes. During the civil war of the 17th century the inhabitants espoused the popular side, and their town was taken by storm in 1644 by the royalists under Prince Rupert and the earl of Derby. The 18th century saw a great stimulus given not only to Bolton but to all England by the inventions of Arkwright and Crompton, who were both natives of the parish. It was here that cotton velvets were made for the first time (in 1756) and muslins (1782) by means of machinery. In 1791 a canal was constructed from Manchester to Bolton, and in the following year an Act of Parliament was passed for enclosing Bolton Moor. This measure was soon succeeded by a large extension of the town, which has since continued to increase from year to year. The municipal borough, with an area of 1748 acres, contained in 1851 10,394 inhabited houses for a population of 61,171; and in 1861, 13,129 houses for a population of 70,395. In 1871 the borough, with an increased area of 1822 acres, included 16,286 houses, and the population was 82,853. The parliamentary borough, which owes its existence to the Reform Bill of 1832, returns two members to parliament.

Arms of Bolton.

BOLZANO, BERNHARD, Catholic theologian and philosopher, was born at Prague on the 5th October 1781. He distinguished himself by his proficiency in mathematics, a study for which he always retained a predilection, and in philosophy. At the age of twenty-four he took orders, and was appointed professor of the philosophy of religion at the philosophical faculty in Prague. His lectures, in which he endeavoured so to present the system of Catholic theology as to show its complete harmony with reason, were received with eager interest by the younger generation of thinkers. But his views met with much opposition; and it was only through the powerful protection of the Prince Archbishop Salm-Salm that he was enabled to retain his chair. At last, in 1820, he was accused of being connected with some of the students' societies, and was compelled to resign his professorship. Several doctrines extracted from his works were condemned at Rome, and he was suspended from his priestly functions. The remainder of his life was devoted to literary work. He died at Prague in 1848. Bolzano's works are very numerous, filling, according to Erdmann, twenty-five volumes. The most important are the *Wissenschaftslehre* (4 vols., Sulzbach, 1837), containing some admirable discussions on logic, and the *Lehrbuch der Religions-wissenschaft* (4 vols., Sulzbach, 1834), which contains a philosophic representation of all the dogmas of the Catholic theology. In some respects it resembles the earlier work of Georg Hermes, for whom Bolzano had a great veneration. Some of the best of his minor works are on the philosophy of mathematics; such are—*Betrachtungen über Elementargeometrie*, *Beiträge zur begründeteren Darstellung der Mathematik*, *Begründung der Lehre von der drei Dimensionen des Raums*. (See *Lebensbeschreibung des Dr Bolzano* (an autobiography), 1836; Wisshaupt, *Skizzen aus dem Leben Dr Bolzanos*, 1850. A good account of Bolzano's philosophical position will be found in Erdmann, *Grundriss der Ges. d. Phil.*, ii. p. 385. 899.)

BOMBAY

BOMBAY, a Presidency and Governorship of British India, consisting partly of British districts, and partly of native states under the protection of Her Majesty's Indian Government. This territory extends from 28° 32′ to 13° 65′ N. lat., and from 66° 43′ to 76° 20′ E. long.; and is bounded on the N. by Beluchistán, the Panjáb, and the native states of Rájputáná; on the E. by the native state of Indor, the Central Provinces, West Berar, and the Nizám's dominions; on the S. by Madras and Mysor; and on the W. by the Arabian Sea. Area, including Sindh, 188,195 square miles, viz., 124,943 British, and 63,252 under Native rule. Population, 25,624,696 souls, viz., British districts, 16,352,623; Native states, 9,272,073. Bombay Presidency comprises three British divisions or commissionerships, the northern, the southern, and the Sindh divisions, with the following 24 districts:—Bombay, Ahmadábád, Kairá, Pánch Mahals, Broach, Surat, Tánná, Kolábá, Khándesh, Násik, Ahmadnagar, Belgám, Kánárá, Dhárwár, Káladgí, Púná, Ratnágiri, Sátárá, Sholápur, Upper Sindh Frontier, Karáchí, Haidarábád, Shikárpur, and Thar Párkar. The Native states are under the supervision of British political officers, and are divided into 16 agencies, viz., Baroda, Kachh, Káthiáwár, Kairá, Surat, Sholápur, Sátárá, Kolhápur, South Marhattá Country, Rewákánta, Máhikánta, Páhlanpur, Sáwantwárí, Tanná, Kolábá, and Dhárwár. The Presidency also includes the Portuguese possessions of Dáman, Diu, and Goa.

PHYSICAL ASPECTS.—The Bombay Presidency consists of a long strip of land along the Indian Ocean from the south of the Panjáb to the north of Mysor, from 25° to 14° 3′ N. lat. The coast is rock-bound and difficult of access; and though it contains several bays forming fair-weather ports for vessels engaged in the coasting trade, Bombay, Karáchí in Sindh, and Kárwár alone have harbours sufficiently land-locked to protect shipping during the prevalence of the south-west monsoon. The coast-line is regular and little broken, save by the Gulfs of Kambay and Kachh, between which lies the peninsula of Káthiáwár.

Mountains.—Speaking generally, a range of hills, known as the Western Ghâts (ghauts), runs down the coast, at places rising in splendid bluffs and precipices from the water's edge, at others retreating inland, and leaving a flat fertile strip of 5 to 50 miles between their base and the sea. In the north of the Presidency on the right bank of the Indus, the Hálá mountains, a continuation of the great Sulaimán range, separate British India from the dominions of the Khán of Khelát. Leaving Sindh, and passing by the ridges of low sand hills,—the leading feature of the desert east of the Indus,—and the isolated hills of Kachh and Káthiáwár, which form geologically the western extremity of the Aravali range, the first extensive mountain range is that separating Gujarát from the states of Central India. The rugged and mountainous country south of the Taptí forms the northern extremity of the Sáhyádri or Western Ghâts. This great range of hills, sometimes overhanging the ocean, and generally running parallel to it at a distance nowhere exceeding 50 miles, with an average elevation of about 1800 feet, contains individual peaks rising to more than double that height. They stretch southwards for upwards of 500 miles, with a breadth of 10 to 20 miles. The western declivity is abrupt, the land at the base of the hills being but slightly raised above the level of the sea. As is usually the case with the trap formation, they descend to the plains in terraces with abrupt fronts. The landward slope is in many places very gentle, the crest of the range being sometimes but slightly raised above the level of the plateau of the Dakhín. Their best-known elevation is Mahábaleshwar, 4800 feet high, a fine plateau, 37 miles from Púna, covered with rich vegetation, and used by the Bombay Government as its summer retreat and sanitarium. In the neighbourhood of the Sáhyádri hills, particularly towards the northern extremity of the range, the country is rugged and broken, containing isolated peaks, masses of rock, and spurs, which, running eastward, form watersheds for the great rivers of the Dakhín. The Sátpurá hills separate the valley of the Taptí from the valley of the Narbadá, and the district of Khándesh from the territories of Indor. The Sátmálá or Ajantá hills, which are rather the northern slope of the plateau than a distinct range of hills, separate Khándesh from the Nizám's dominions.

Plains.—The more level parts of Bombay consist of five well-demarcated tracts—Sindh, Gujarát, the Konkan, the Dakhín or Deccan, and the Karnatic. Sindh, or the lower valley of the Indus, is very flat, with but scanty vegetation, and depending for productiveness entirely on irrigation. Gujarát, except on its northern parts, consists of rich, highly cultivated alluvial plains, watered by the Táptí and Narbadá, but not much subject to inundation. The Konkan lies between the Western Ghâts and the sea. It is a rugged and difficult country, intersected by creeks, and abounding in isolated peaks and detached ranges of hills. The plains of the Dakhín and Khándesh are watered by large rivers, but as the rainfall is uncertain, they are generally, during the greater part of the year, bleak and devoid of vegetation. The Karnatic plain, or the country south of the River Krishná, consists of extensive tracts of black or cotton soil in a high state of cultivation.

Rivers.—The chief river of Western India is the Indus, which enters the Presidency from the north of Sindh, and flowing south in a tortuous course, falls into the Arabian Sea by several mouths, such as the Ghizrí creek, Khudí creek, Pitiání creek, Sisá creek, Hajámrí creek, Vatho creek, Mall creek, Wárí creek, Bhitiárá creek, Sir creek, and Khorí creek. In the dry season the bed varies at different places from 480 to 1600 yards. The flood season begins in March and continues till September, the average depth of the river rising from 9 to 24 feet, and the velocity

sea near the head of the Gulf of Kambay. The streams which, rising in the Sáhyádri range, or Western Gháts, flow westward into the Arabian Sea, are of little importance. During the rains they are formidable torrents, but with the return of the fair weather they dwindle away, and during the hot season, with a few exceptions, they almost dry up. Clear and rapid as they descend the hills, on reaching the lowlands of the Konkan they become muddy and brackish creeks. The Kanarese rivers have a larger body of water and a more regular flow than the streams of the Konkan. One of them, the Sheráwati, forcing its way through the western ridge of the Gháts, plunges from the high to the low country by a succession of falls, the principal of which is 890 feet in height. The Sáhyádri, or Western Gháts, also throw off to the eastward the two principal rivers of the Madras Presidency, the Godávarí and the Krishná. These rivers collect countless tributary streams, some of them of considerable size, and drain the entire plain of the Dakhin as they pass eastward towards the Bay of Bengal.

Lakes.—The Manchar Lake is situated on the right bank of the Indus. During inundations it attains a length of 20 miles, and a breadth of 10, covering a total area estimated at 180 square miles. But the most peculiar lacustrine feature of the Presidency is the Ránn or Lake of Kachh (*Cutch*), which, according to the season of the year, is a salt marsh, an inland lake, or an arm of the sea. Its area is estimated at 8000 square miles. It forms the western boundary of the province of Gujarát, and when flooded during the rains, unites the Gulfs of Kachh (Cutch) and Kambay, and converts the territory of Kachh into an island. In the dry season the soil is impregnated with salt, the surface in some places being moist and muddy, and in others, like a dry river bed or sea-beach, strewn with gravel or shingle. The Ránn is now used as the great source of salt supply for the whole Presidency. Its present condition is probably the result of some natural convulsion. But whether the Ránn is an arm of the sea from which the waters have receded, or an inland lake whose seaward barrier has been swept away, still remains a matter of discussion.

Climate.—Great varieties of climate are met with in the Presidency. In its extreme dryness and heat, combined with the aridity of a sandy soil, Upper Sindh resembles the sultry deserts of Africa. The mean maximum temperature at Haidarábád, in Lower Sindh, during the six hottest months of the year, is 98° 5′ in the shade, and the water of the Indus reaches blood heat; in Upper Sindh it is even hotter, and the thermometer has been known to register 130° in the shade. In Kachh and in Gujarát the heat, though less, is still very great. The Konkan is hot and moist, the fall of rain during the monsoon sometimes approaching 300 inches. The table-land of the Dakhin above the Gháts, on the contrary, has an agreeable climate except in the hot months, as has also the southern Marhattá country; and in the hills of Mahábaleshwar, Singarh, and other detached heights, Europeans may go out at all hours with impunity. Bombay Island itself, though in general cooled by the sea breeze, is oppressively hot during May and October. The south-west monsoon generally sets in about the first week in June, and pours down volumes of rain along the coast. From June to October travelling is difficult and unpleasant, except in Sindh, where the monsoon rains exert little influence.

Forests.—Bombay Presidency possesses two great classes of forests—those of the hills and those of the alluvial plains. The hill forests are scattered over a wide area, extending from 23° to 14° N. lat. Most of them lie among the Sáhyádri hills or Western Gháts. The alluvial forests lie in Sindh, on or close to the banks of the Indus, and extend over an area of 550 square miles. The principal timber trees in the forests are—teak; blackwood of two varieties (*Dalbergia Sisu* and *Dalbergia latifolia*), *Dalbergia ujainensis*, *Pterocarpus Marsupium*, *Terminalia glabra*, *Acacia arabica*, *Acacia Catechu*, *Nauclea cordifolia*, *Nauclea parvifolia*, *Bidelia spinosa*, *Hardwickia binata*, *Juga xylocarpa*, *Populus euphratica*, and *Tamarix indica*. The forests contain many trees which, on account of their fruits, nuts, or berries, are valuable, irrespective of the quality of their timber. Among these are the mango (*Mangifera indica*); the jack (*Artocarpus integrifolia*), *Zizyphus Jujuba*, *Ægle Marmelos*, *Terminalia Chebula*, *Calophyllum Inophyllum*, *Bassia latifolia*, and *Pongamia glabra*. The jungle tribes collect gum from several varieties of trees, and in Sindh the Forest Department derives a small revenue from lac. The palms of the Presidency consist of cocoa-nut, date, palmyra, and areca catechu.

Geology.—Geologically the Bombay Presidency is divided into two tracts: the north-western part, consisting of Sindh, Kachh (Cutch), and Gujarát; and the south-western, comprising the Marhattá country. Undulating sandy plains, with scattered craggy hills, are found in Gujarát; the immense alluvial flats to the north being, for the most part, deserts of blown sand, and the fertile country consisting of a belt along the borders of the sea. In Sindh, the country, except on the banks of the Indus, or where reclaimed by irrigation, is an arid tract of gravel and sand, from which rise steep scarps of limestone ranges. The rocks of Gujarát, Kachh, and Sindh, are only partially represented in the more southern peninsula, and are continuous with the formations found in Persia and Arabia. In the Marhattá country the greater portion of the surface is composed of nearly horizontal strata of basalt and similar rocks.

POPULATION.—The census of 1872 returns the total area of the Presidency, including Sindh, at 188,195 square miles, and the total population at 25,624,696 souls. Details, however, are only available for the British part of the Presidency, which contains an area of 124,943 square miles, and a total population of 16,352,623 souls. The average density of population in the British districts is 131 persons per square mile, but it varies from a maximum of 29,291·13 in Bombay city to 14·20 in Thar and Párkar. Total number of houses in the British districts, 2,164,338; and average number of persons per house, 4·99. Of the total population of the British portion, 12,440,659, or 76·08 per cent., are Hindus; 2,847,756, or 17·4 per cent., Muhammadans; 192,245, or 1·17 per cent., Buddhists; 106,133, or 0·65 per cent., Christians; 67,115, or 0·41 per cent., Pársís; 603,836, or 3·69 per cent., aborigines; and 94,879, or 0·58 per cent., of unspecified religion or nationality. The males number 8,547,100, or 52 per cent. of the population; the females, 7,805,523, or 48 per cent. The percentage of the total number of children under twelve years of age is 31·65. The Hindus are most numerous in Satára, and fewest in the Upper Sindh Frontier district. The Muhammadans form nearly the whole population of Sindh, and are least numerous in the Pánch Mahals. Except in Sindh, the Buddhists are widely scattered throughout the whole Presidency. The Christians are chiefly confined to Bombay city, Tánná, the Indo-Portuguese possessions, and the larger cantonments, such as Púna. The British districts of the Presidency contain upwards of 26,800 villages, and 175 towns of upwards of 5000 inhabitants. Besides Bombay city, there are 213 municipalities established under Act 26 of 1850. Of these, 4 have an income of over £10,000; 27 of over £1000; 22 of over £500; 94 of over £100; and 66 of under £100. Exclusive of the town of Bombay, the total municipal revenue realised in 1872–73 amounted to £198,857. Average rate of municipal taxation, 2s. 1½d. per head of the town population. The principal sources of municipal

revenue are the *octroi* duties, house tax, and wheel tax.

Agricultural Products.—The staple crops are as follows:—Joár (*Sorghum vulgare*) and bájrá (*Holcus spicatus*) are the staple food grains in the Dakhin and Khándesh. Rice is the chief product of the Konkan. Wheat, generally grown in the northern part of the Presidency, but specially in Sindh and Gujarát, is exported to Europe in large quantities from Karáchí, and on a smaller scale from Bombay. Barley is principally grown in the northern parts of the Presidency. Náchaní (*Eleusine coracana*) and Kodrá (*Paspalum scrobiculatum*), inferior grains grown on the hill sides, furnish food to the Kulís, Bhils, Wáralis, and other aboriginal tribes. Of the pulses the most important are gram (*Cicer arietinum*), túr (*Cajanus indicus*), kultí (*Dolichos biflorus*), and mug (*Phaseolus Mungo*). Principal oil-seeds: til (*Sesamum orientale*), mustard, castor-oil, safflower, and linseed. Of fibres the most important are cotton, Dakhiní hemp (*Hibiscus cannabinus*), and san or tág (*Crotolaria juncea*). Much has been done of late years to improve the cotton of the Presidency. American varieties have been introduced with much advantage in the Dhárwár collectorate and other parts of the southern Marhattá country. In Khándesh the indigenous plant from which one of the lowest classes of cotton in the Bombay market takes its name, has been almost entirely superseded by the superior Hinganghát variety. Miscellaneous crops:—Sugar-cane, requiring a rich soil and a perennial water supply, and only grown in favoured localities, red pepper, potatoes, turmeric, and tobacco. In 1871–72, 3,379,937 acres were under cotton cultivation; in 1872–73 the area increased to 3,715,945 acres. The total out-turn was 260,444 *candies* (560 lb) in 1872–73, against 221,144 in 1871–72. A legislative enactment has been passed to prevent adulteration of cotton, and in 1872–73, 24 persons were convicted under it. In 1872–73, 2281 steam cotton gins were at work with 158 steam presses. Two model farms have been established in the Presidency—one at Hálá, near Haidarábád, in Sindh, and the other in Khándesh. Experiments have been instituted in the cultivation of fibres and tobacco. Large quantities of Carolina rice seed were distributed over the country, but the results hitherto cannot be deemed to have been successful. The same may be said of the endeavours which have been made to propagate the cinchona tree near Mahábaleshwar. Acreage under principal crops—Joár, 6,552,385 acres; bajrá, 4,560,271; rice, 2,009,115; wheat, 1,322,835; and pulses, 1,167,809 acres. The land system of the Presidency is complicated, each province having a variety of tenures of its own. But the most important, and by far the most universal, is the survey tenure created by the British administration, which gives a right of occupancy to the holder on condition of his paying the Government demand.

Public Works and Railways.—In 1872–73 the sum of £1,180,000 was expended on account of Public Works in the Bombay Presidency; and the allotment under this head tends annually to increase. In the same year there were five railways open—1. The Great Indian Peninsula Railway: total miles open, 1278; total capital invested, £25,569,568; total receipts during the year, £1,872,826; working expenses, £1,203,200; net profit, £669,626. 2. The Bombay, Baroda, and Central India Railway: miles open, 389; capital invested, £8,418,202; receipts, £564,931; working expenses, £338,786; net profit, £226,145. 3. The Khámgáon State Railway: miles open, 8; capital invested, £48,530; receipts, £1241; working expenses, £562; net profit, £679. 4. The Amráoti Railway: miles open, 5½; capital invested, £43,730; receipts, £2302; working expenses, £1241; net profit, £1061. 5. The Sindh section of the Sindh Panjáb and Dehli Railway: miles open, 106; capital invested, £2,646,106; receipts, £157,100; working expenses, £118,934; net profit, £38,166. Total miles open of the above five railways, 1786½; total capital invested, £36,726,136; total receipts in 1872, £2,598,400; total working expenses, £1,662,723; total net profit, £980,667. Besides these, the following railways are either in progress or about to be undertaken:—(1), State line, Southern Marhattá country; (2), Native State line, Viráwal, Junágarh, and Dhoráji; (3), Pátrí Branch (State line, light rail); (4), Anand and Dákor Branch; (5), Migángáon and Dhaboi Railway; (6), Wardhá to Hinganghát and Waroră: (7), Wadi to Haidarábád; (8), Khandwá to Indor. In 1872–73 the Bombay Telegraph Department had 4406 miles of wire in operation.

Post-Offices.—In 1872–73, 447 post-offices were distributed over the Presidency; total mileage of postal lines, 10,208 miles; total number of letters, parcels, &c., despatched and received, 17,601,982.

Mines and Quarries.—The Presidency of Bombay though deficient in mineral wealth, is abundantly supplied with stores of stone fitted for building and road-making purposes. At Teagar, in the Dhárwár district, iron-ore is mined and smelted, but the scarcity of fuel prevents operations being conducted on an extensive scale. There are also large slate quarries in Dhárwár. Mándargé hill is quarried extensively for stone, the right of working it being annually sold by public auction. In Belgám district are quarries, from which building stones, stone bricks, or oblong quadrangular blocks of soft rock are obtained in abundance. Limestone is also found in the river beds of this district. There are a few trap and laterite quarries in the Ratnágiri district. The trap stone is used for tank and well building, and for the plinths of houses; the laterite is used for house-building. Near Karáchí are five quarries containing a species of limestone, largely used in buildings in that town.

Manufactures.—The indigenous manufactures of the country have rapidly declined since the influx of Manchester goods. But cotton weaving is still carried on upon a small scale in every village of any importance. Dyeing is practised in most places where fresh water is procurable. Printed cotton goods are manufactured in all the large towns of Gujarát, and the further the locality is removed from the direct influence of railways the better the work is. This is owing to the competition of European cotton goods, which are sold much cheaper, and are more brilliant in colour, although less strong and durable, than the native manufactures. Most of the lower classes still wear home-spun and woven goods; but the cotton-mills erected in

that number; and the low rates of wage, with the natural aptitude of the native for textile work, enables the Bombay mill-owners to compete with the Lancashire manufacturers, notwithstanding the heavy cost of importing machinery and of European supervision. Several of the mills have a capital of some hundreds of thousands sterling invested in them; and their superior reputation for turning out unglazed and genuine goods has almost driven the lower qualities of Manchester fabrics from the market. In 1873 fifteen mills were at work in the town and island of Bombay, and five in other parts of the Presidency. Most of them have both spindles and looms, and their yarn and piece goods find a ready market. In Ahmadábád, Surat, Yeolá, Násik, and Bombay, considerable quantities of silk goods are made, the silk being imported from China either in the cocoon or in skeins. Gold and silver thread enter largely into the manufacture of silk and cotton fabrics. The *kinkháb* (kincob), the richest kind produced, is either gold thread and silk, or silver, gold, and silk. Embroidery in silk cloth and cotton, and in gold, silver, and silk thread, is carried on to some extent in Haidarábád, in Sindh, principally for European markets. Fibres are used for the manufacture of paper in Ahmadábád, Baroda, Surat, Násik, Bombay, and Kolhápur. Mats, beds, &c., are manufactured from cocoa-nut fibre. Leather is worked into a variety of articles throughout the Presidency. The manufactures of minor importance consist of pottery, brass, and copper utensils, cutlery, and agricultural implements, gold and silver ornaments, carved wood, ivory work, &c.

TRADE.—The total value of the external trade of the Presidency for 1872–73 was as follows:—Bombay Port—imports, £17,388,953; exports, £19,117,081; re-exports, £5,140,924; total, £41,646,958. Minor ports—imports, £395,238; exports, £729,028; re-exports, £13,368; total, £1,137,634. Sindh ports—imports, £1,677,399; exports, £1,991,556; total, £3,668,955. Aden—imports, £1,407,102; exports, £834,087; total, £2,241,189. Total of the Presidency — imports, £20,868,692; exports, £22,671,752; re-exports, £5,154,292; total, £48,694,736. In the same year 5314 ships, having a tonnage of 902,157 tons, cleared from Bombay harbour, and 5208 ships, of 161,907 tons, from the minor ports. Principal articles of commerce—cotton, cotton piece-goods, wool and woollen piece goods, machines and machinery, oils, tea, wines and spirits, metals, coal, candles, jute and gunny cloths, apparel, sugar and sugar-candy, twist, hides and skins, grain and pulse, bullion, &c. In 1872–73 upwards of 55,300 tons of cotton were imported into Bombay in the shape of Manchester goods, and 143,017 tons of raw cotton exported from it.

REVENUE AND EXPENDITURE.—The total revenue of the Presidency for the year 1872–73 amounted to £9,980,043, and the expenditure to £8,027,040. The principal heads of revenue are as follows:—Land revenue, £3,751,050; tributes and contributions from native states, £92,337; forests, £114,640, excise, £418,746; assessed taxes, £110,098; customs, £667,825; salt, £885,013; opium, £2,614,897; stamps, £527,382; law and justice, £29,677; marine, £64,475; interest, £103,209. The settlement of the land revenue is usually made for thirty years. A revision of the thirty years' settlement of Poona, Násik, and Sholápur districts, is now (1874) in progress.

STATISTICS OF PROTECTION.—The military strength of the Bombay Presidency consists of 1250 European commissioned officers, 11,067 European non-commissioned officers and rank and file, 27,002 Native commissioned and non-commissioned officers and rank and file; total, 39,319. The whole are under the control of a separate commander-in-chief for Bombay. Ten ships constitute the strength of the Bombay marine. The regular police of Bombay consisted in 1872–73 of 18,166 officers and men, maintained at a total cost of £305,810; the average being 1 man to every 6·8 square miles of the area, and to 900 of the population.

EDUCATION.—The University of Bombay, established in 1857, is a body corporate, consisting of a chancellor, vice-chancellor, and fellows. The Governor of Bombay is *ex-officio* chancellor. The Educational Department is under a director of public instruction, who is responsible for the administration of the department in accordance with the general educational policy of the state. In 1872–73 the number of schools and colleges aided by the state or under its inspection was as follows:—7 colleges, attended by 544 pupils; 4 professional schools, with 275 pupils; 41 high schools, 7167 pupils; 176 middle class schools, 16,612 pupils; 3595 lower class schools for boys, 182,147 pupils; 253 lower class schools for girls, 10,885 pupils; 12 normal schools, 602 pupils; total, 4088 schools, 218,466 pupils. The total cost for the schools was £285,650, of which the state contributed £99,600; the balance being obtained from school fees, local contributions, private endowments, &c.

HISTORY.—The territories now comprising the Presidency of Bombay formed in ancient times several separate Hindu kingdoms, among which Mahárásthra, Gujarásthra, Sindhu, were the most important. As in other parts of India, the great majority of the people are Hindus, with more recent accretions of Muhammadans, and a sprinkling of hill-tribes practising non-Hindu rites, and representing the pre-Aryan races. The first Muhammadan invasion of which we have authentic accounts is that of Mahmúd of Ghazní, who, in 1024 A.D., invaded Gujarát with a large army, destroyed the national Hindu idol of Somnáth, and carried away an immense booty. Muhammad Ghorí also invaded Gujarát, and left a garrison in its capital. But it was not till after the Musalmán power was firmly established in Northern India that the Muhammadan sovereigns of Dehli attempted the conquest of the south. In 1294 the Emperor Alá-ud-din first invaded the Dakhin (Deccan), and in 1297 he conquered Gujarát. In 1312 the Muhammadan arms were triumphant through the Marhattá country; and seven years later the whole of Malabar fell a prey to the invaders. In the middle of the 14th century the weakness of the Dehli sovereigns tempted the governors of provinces to revolt against their distant master, and to form independent kingdoms. In this way the Báhminí kingdom was established in the Dakhin, and embraced a part of the Bombay Presidency. Ahmadnagar and Gujarát also became the seats of a new kingdom. In 1573 Akbar conquered Gujarát and reannexed it to the empire, and in 1601 he effected the reconquest of Ahmadnagar and Khándesh. From this time the country was never tranquil, and Ahmadnagar became the focus of constant rebellions. During the latter part of the 17th century the Marhattás rose into power, and almost every part of the country now comprising the Presidency of Bombay fell under their sway.

As early as 1532 A.D. the island of Bombay was occupied by the Portuguese. The Dutch and English made an unsuccessful attempt to gain possession of the island in 1627, and in 1653 proposals were suggested for its purchase from the Portuguese. In 1661 it was ceded to the English Crown, as part of the dower of the Infanta Catherina on her marriage with Charles II. So lightly was the acquisition esteemed in England, and so unsuccessful was the administration of the Crown officers, that in 1668 Bombay was transferred to the East India Company for an annual payment of £10. The population at that time did not exceed 10,000 souls, and so unhealthy was the climate, that three years were regarded as the average duration of the life of its European inhabitants. At the time of the

transfer, powers for its defence and for the administration of justice were also conferred; a European regiment was enrolled; and the fortifications erected proved sufficient to deter the Dutch from their intended attack in 1673. In 1687 Bombay was placed at the head of all the Company's possessions in India; but in 1753 the Government of Bombay became subordinate to that of Calcutta. The first English settlement in the Bombay Presidency was in 1618, when the East India Company established a factory at Surat, protected by a charter obtained from the Emperor Jahángír. After the termination of the second Marhattá war in 1803, the East India Company obtained the districts of Surat, Broach, Kairá, &c.; and on the overthrow of the Peshwá in 1818, they annexed Púná, Ahmadnagar, Násik, Sholápur, Belgám, Kálaugí, Dhárwár, &c. Sindh was conquered in 1843, and became a part of the British empire. The native states under the supervision of the Government of Bombay are divided, historically and geographically, into two main groups. The northern or Gujarát group includes the territories of the Gaikwár, with the smaller states which form the administrative divisions of Kachh, Páhlanpur, Rewá Kánta, and Máhi Kánta. These territories, with the exception of Kachh (Cutch), have an historical connection, as being the allies or tributaries of the Gaikwár in 1805, when final engagements were concluded between that prince and the British Government. The southern or Marhattá group includes Kolhápur, Akalkot, Sáwantwárí, and the Sátárá and southern Marhattá Jágírs, and has an historical bond of union in the friendship they showed to the British in their final struggle with the power of the Peshwá in 1818. The remaining territories may conveniently be divided into a small cluster of independent zamíndáris, situated in the wild and hilly tracts at the northern extremity of the Sáhyádri range, and certain principalities which, from their history or geographical position, are to some extent isolated from the rest of the Presidency.

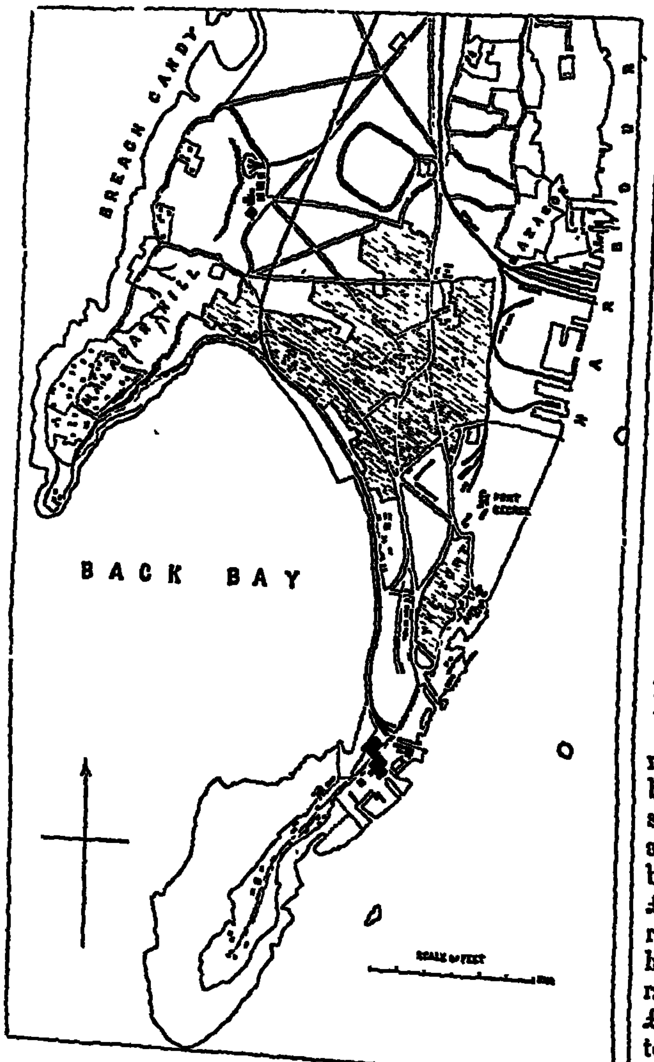
Administration.—The Government of Bombay is administered by a Governor in Council, the latter consisting of the Governor as president, two ordinary civil members, and, as a rule, the commander-in-chief of the Bombay army. These are the executive members of Government. For making laws there is a legislative council, consisting of the Governor and his Executive Council, with certain other persons, not fewer than four or more than eight in number, nominated by the Governor to be members of council for legislative purposes only, and intended to represent the non-official European and Native communities. Each of the members of the Executive Council has in his charge one or two departments of the Government; and each department has a secretary, an under-secretary, and an assistant secretary, with a numerous staff of clerks. The political administration of the native states is under the superintendence of British agents placed at the principal native courts; their position varies in different states according to the relations in which the principalities stand with the paramount power. The administration of justice throughout the regulation districts of the Presidency is conducted by a High Court at Bombay, consisting of a Chief Justice and seven Puisne judges, along with district and assistant judges throughout the districts of the Presidency. The revenue administration of the regulation districts is carried on by two revenue commissioners, seventeen collectors, twenty assistant collectors, and a varying number of supernumerary assistants. (W. W. H.)

Bombay City and Island.

The Island of Bombay, with an area slightly in excess of 22 square miles, is situated in 18° 53' 54" N. lat., and 72° 52' E. long. It consists of a plain about 11 miles long by 3 broad, flanked by two parallel lines of low hills. A neck of land stretching towards the south-west forms the harbour on its eastern side, sheltering it from the force of the open sea, and enclosing an expanse of water from 5 to 7 miles wide. At the south-west of the island, Back Bay, a shallow basin rather more than 2 miles in breadth, runs inland for about 3 miles between the extreme points of the two ranges of hills. On a slightly raised strip of land between the head of Back Bay and the harbour is situated the fort, the nucleus of the city of Bombay. From this point the land slopes westward towards the central plain, a low lying tract, which before the construction of the embankment known as the Hornby Velard, used at high tide to be submerged by the sea. To the north and east, although causeways and railway embankments have now shut out the sea, a large area of salt-marsh land still remains subject to inundation.

In the foregoing article on the Bombay Presidency it is explained that Bombay Island passed to the English Crown as part of the dower of the Infanta Catherina, on her marriage with Charles II., and that although the new acquisition was at first despised, it rose in 1687 to the chief importance in the East India Company's possessions. In the next century it declined before the growth of Calcutta, and sank into a subordinate settlement. The present century has again witnessed a revolution in its fortunes. Its splendid harbour and comparative nearness to the Suez Canal, with the system of railways which now connect Bombay with the other Presidencies, have marked out for it a career scarcely second, if at all second in commercial importance, to that of Calcutta itself. The sudden demand for Indian cotton, which resulted from the American war, gave an unprecedented rapidity to its development. The cotton of Gujarát, Dhárwár, and other parts of Bombay, is much superior to the Bengal fibre. Several years of brilliant prosperity culminated in 1866–67 in a financial crisis, that left the commerce of Bombay in a shattered state. Depending as it does chiefly on the one article of cotton, along with some export of grain and the Government opium, the trade of Bombay rests on a narrower basis than that of Calcutta, which in years of misfortune has a large variety of staples to fall back upon, such as tea, indigo, jute, rice, hides, oil-seeds, &c. Moreover, Bombay has only the costly railway communication with the interior parts of India, while Calcutta commands the confluence of two of the greatest river systems in the world, the Brahmaputra and the Ganges. Nevertheless, Bombay is pressing close upon Calcutta as the commercial capital of India. Its imports are about as great, and its exports not very far short. In 1871–72 its total trade was £50,384,929 against a total of £54,136,829 in Calcutta. In that year the Bombay imports were 22½ millions sterling; the exports, 23½ millions, and the re-exports, 4½ millions: total, 50½ millions sterling.

buildings are on the American scale, and have no rival in any other city of India. The private houses of the European residents lie apart alike from the native and from the mercantile quarters of the town. As a rule, each is built in a large garden or *compound;* and although the style of architecture is less imposing than that of the stately residences in Calcutta, it is well suited to the climate, and has a beauty and comfort of its own. The favourite suburb is Malabar hill, a high ridge running out into the sea, and terraced to the top by handsome houses, which command one of the finest views in the world. To the right of this ridge, looking towards the sea, runs another suburb known as Breach Candy, built close upon the beach and within the refreshing sound of the waves. To the left of Malabar hill the island forms a spacious bay, with a



Ground-Plan of Bombay.

promontory at the other side, which marks the site of the old Bombay Fort. The fort is now a mere garrison, with small pretensions to defensive capabilities. Its walls are demolished, and its area is chiefly devoted to mercantile buildings. Further round the island, beyond the fort, is Mazagon Bay, commanding the harbour, and the centre of maritime activity. The defences of the port consist chiefly in ironclad "Monitors" anchored off the town, with one or two fortified islands, and the guns which still line a portion of the old fort walls that have been left standing towards the sea. The census of 1872 disclosed a population of 644,405 souls; of whom 408,680, or 63·42 per cent., are Hindus; 138,815, or 21·54 per cent., Muhammadans; 44,091, or 6·84 per cent., Pársís; 15,121, Buddhists and Jains; 34,705, or 5·39 per cent., European, African, Eurasian, and Native Christians, with 2993 classified under the head of "others." Dyeing, tanning, and working in metals may be noticed as specially active trades, but the most progressive and important industry is the manufacture of yarn and cotton cloth. In 1873 there were 5 steam spinning and weaving mills in Bombay, giving employment to about 11,000 hands. In these factories 380,000 spindles and 5000 looms were at work. A considerable section of the population is supported by the cultivation of cocoa-nut trees and the preparation of intoxicating drinks from the juice of the different species of palm. Rice is the chief agricultural product, but many varieties of garden vegetables are profitably cultivated. Of these the most common are onions, "bhendis" (*Abelmoschus esculentus*), and gourds of different sorts. The imperial revenue from the town and island of Bombay is derived from two sources,—the one supervised by the collector of Bombay, the other by the commissioner of customs. The total receipts for the past year, under the first head, amounted to £148,287, of which £23,131 was derived from land, £17,250 from excise, and £107,906 from stamps. The total amount collected by the commissioner of customs was £3,252,714, of which the customs yielded £609,630, and the export duty on opium £2,643,084. Owing to the difficulty of procuring colonists in the early days of the settlement, the land is generally held on easy terms,—the payment to Government being in most cases of the nature of a quit rent, free from enhancement or resettlement as long as the land is used for cultivation only. Of the whole area, 13 miles are returned as cultivated, and 9 as unculturable. During the year 1872 there were 101 schools in Bombay, attended by 11,351 scholars, or 1 to every 56 of the entire population. The total strength of the local police force in 1872 was 1402, or 1 policeman to every 459 inhabitants. Of the entire number, 1124 are municipal, and 278 Government police. Of the former, 35 are European, and 13 are mounted Native police. The Government police are employed on harbour duty and as guards for Government offices. Eight of them are Europeans

Municipal Statistics.—The limits of the Bombay municipality extend over the whole of the island of Bombay, including, as stated above, a population of 644,405 souls. The total municipal revenue for the year 1873 amounted to £314,645, of which £223,041 was raised by taxation, £59,958 on account of services rendered, and £31,646 from municipal property and miscellaneous receipts The following are the main items under the head of taxation proper:—House rate, £73,587; police rate, £24,189; lighting rate, £21,179; wheel taxes, £23,197; tobacco and liquor duty and licenses, £28,690; town duties, £45,200; and additional rates from Port Trust, £4000. Under the head, Service rendered, are included the Halálkar cess and the water rate, yielding respectively £20,392 and £39,566. The returns under the third head are chiefly receipts from the Crawford markets. The total expenditure was £312,208. Of this amount £25,325 was spent on general supervision, £36,041 in supporting the police and fire brigade. Under the head of public health, £87,574 was spent, and £84,835 on public works. The interest and sinking fund on the police debt consumed £74,496. The incidence of municipal taxation per head of the population is 6s. 9d. It is estimated that the gross annual income of the city is about 855 lakhs of rupees, or upwards of 8½ millions sterling, on which sum the municipal taxation proper amounts to about 2·57 per cent., and the total municipal income and expenditure to about 3·64 per cent. The municipal debt at present amounts to about £790,000, or nearly 2½ years' income.

(W. W. H.)

BONALD, Louis Gabriel Ambroise, Vicomte de, philosopher and politician, was born at Monna, near Milhaud, in Rouergue, France, on the 2d October 1754. He served for some years in the king's musketeers, and after his marriage was made mayor of his native place. Dissatisfied with the revolutionary principles then being acted upon, he emigrated in 1791, and joined the army of the Prince of Condé. Soon afterwards he settled, with his family, at Heidelberg, where he wrote his first important work, *Théorie du pouvoir politique et réligieux dans la Société civile*, 3 vols., 1796, in which his conservatism and reactionary views are fully expounded and illustrated. In this work, too, he predicted the certain return of the Bourbons to France. The book was condemned by the Directory, and in France very few copies escaped detection. Naturally, on his return to his native country, M. de Bonald found himself an object of suspicion, and was obliged to live in retirement. He still continued to publish works of the same tendencies,—his *Essai analytique sur les Lois naturelles de l'ordre social* appearing in 1800, the *Législation primitive* in 1802, and the treatise *Du Divorce considéré au XIX^me Siècle* shortly after. In 1806 he was associated with Chateaubriand and Fiévée in the conduct of the *Mercure de France;* and two years later, after great persuasion, he allowed himself to be appointed councillor of the Imperial University, which he had often attacked. After the Restoration he was made member of the Council of Public Instruction, and from 1815 to 1822 he sat in the chamber as deputy. His speeches and votes were invariably on the extreme Conservative side; he even advocated a literary censorship. In 1822 he was made minister of state, and presided over the commission in whose hands the censorship rested. In the following year he was raised to the rank of peer, a dignity which he lost through refusing to take the oath in 1830. From 1816 onwards he had been a member of the Academy. He took no part in public affairs after 1830, but retired to his country-seat at Monna, where he died on the 23d November 1840.

Bonald was one of the most able and vigorous writers of the theocratic or reactionary school, which comprehended among its numbers such men as De Maistre, De Lamennais, Ballanche, and D'Eckstein. The great bulk of his writings belong to the department of social or political philosophy; but all the results at which he arrives are deductions from a few principles. The one truth which to him seemed, in fact, all-comprehensive was the divine origin of language. In his own somewhat enigmatic expression, *L'homme pense sa parole avant de parler sa pensée,* words and thoughts are inextricably linked together; the first language contained the essence of all truth. From this premise he draws his proof for the existence of God, and for the divine origin and consequent supreme authority of the Holy Scriptures. The infallibility of the church as the exponent of spiritual truth readily follows. While this thought lies at the root of all his speculations there is a formula of constant and significant application. All relations are by him reduced to the triad of cause, means, and effect, which he sees constantly repeated throughout all nature. Thus, in the universe there are the first cause as mover, movement as the means, and bodies as the result; in the state we have power as the cause, ministers as the means, and subjects as the effects; in the family we have the same relation exemplified by father, mother, and children. It is also to be remarked that these three terms bear specific relations to one another, the first is to the second as the second is to the third. Thus, in the great triad of the religious world,—God, the Mediator, and Man,—God is to the God-Man as the God-Man is to Man. It will be readily apparent how Bonald was able from these principles to construct a complete system of political absolutism, for the sufficiency of which only two things were wanted,—well-grounded premises instead of baseless hypotheses, and the harmony of the scheme with the wills of those who were to be subjected to it. Bonald's style is remarkably fine; ornate, but pure and vigorous. Many fruitful thoughts are scattered among his works, which have been popular with a certain party; but his system scarcely deserves the name of a philosophy.

Besides the above-mentioned works, Bonald published *Recherches Philosophiques sur les premiers objets de Connaissances Morales*, 2 vols., 1818; *Mélanges littéraires et politiques, Démonstration philosophique du principe constitutif de la Société*, 1830. The first collected edition appeared in 12 vols., 1817–19; the latest is that in 3 vols., with introductory notice by the Abbé Migne. See *Notice sur M. le Vicomte de Bonald*, 1841 (by his son), and Damiron, *Phil. en France au XIX^me Siècle.*

BONAPARTE, or, as it was originally spelled, Buonaparte, the name of the Italian family from whom the great Napoleon was descended. The father of the first emperor, Carlo Maria Bonaparte, was born at Ajaccio in 1746. He was a lawyer by profession, and took a vigorous part in Paoli's insurrection. In 1781 he was one of the members of the council of Corsican nobility; he also held the post of assessor of Ajaccio. In 1785 he died of cancer in the stomach at Montpellier, whither he had removed for his health. His wife, Letizia Ramolino, born in 1750, was celebrated for her majestic beauty and resolute courage. She accompanied her husband through the campaigns with Paoli, and in 1793 emigrated with her family to Marseilles, where for a time she lived in great penury. After her son was made first consul she removed to Paris, and, on the establishment of the empire, received the title of Madame Mère. She cared little for display; and her frugal style of living frequently displeased Napoleon. After the battle of Waterloo she took up her abode in Rome, where she continued to reside till her death in 1836. Of her large family of thirteen, eight survived their father and have become known in history. These in order of age are—

I. Joseph, the eldest son, born on the 7th January 1768. He was placed, along with his younger brother Napoleon, at the school of Autun, from which the latter was soon afterwards withdrawn. On completing his education he contemplated a military career, but, on the death of his father, devoted himself to the care of his family. He studied law at the University of Pisa, and was received as an advocate in Corsica. He and his brother eagerly embraced the revolutionary side, and in 1793 the whole family were compelled to emigrate to Marseilles. In the following year he married Mlle, Clary, daughter of a rich merchant, whose younger sister afterwards became the wife of Bernadotte. Two years later, when Napoleon was made general of the army of Italy, Joseph accompanied

useful only in so far as it contributed to the support of his own power. The Neapolitans soon discovered that their king was but a mouth-piece, and learned to despise him; and his rule was disturbed by constant insurrections. In the beginning of 1808 Napoleon began to communicate with his brother regarding the affairs of Spain; and finally, on the 10th May, wrote to him that the Spanish throne was vacant, and that he had destined it for him. Joseph, with many forebodings, was obliged to accept; and for a short time matters seemed sufficiently smooth. But the smouldering discontent soon broke out into open flame over the land, and the Spaniards, assisted by the British and Portuguese, made a struggle for freedom. Joseph's influence in the kingdom was a nullity; the people had never accepted him, and Napoleon, by giving absolute command to his various marshals, robbed his brother of all real power. Thrice the new king was compelled to fly from Madrid, and it was with difficulty that he escaped after the final battle of Vittoria. During the great struggle of 1814 Joseph acted as lieutenant-general of the empire, and as adviser-in-chief to the empress-regent. Under his brother's orders he sent off Maria Louisa and her son to Blois when the allied army approached Paris; and it was on his authority that Marmont treated for the capitulation of the city. For these acts he has sometimes been blamed, but with scant justice. While Napoleon was in Elba Joseph took up his residence in Switzerland; but he rejoined his brother in Paris during the Hundred Days. After the abdication he had an interview with the fallen emperor at the Isle of Aix, and generously offered to give up to him his own means o. escape. The proposal not being accepted, he sailed for America and settled near Philadelphia, at Point-Breeze, on the banks of the Delaware. Here he lived for some years under the title of Comte de Survilliers, endeared to the inhabitants by his liberality and gracious manners. After the July revolution of 1830 he wrote a long and eloquent letter, advocating the claims of his nephew, the duke of Reichstadt, to the French throne. Two years later he visited England, where he resided for some years, and to which he paid a second visit in 1839 In 1841 he was permitted to enter Genoa and Florence where his wife resided. In the latter city he died on the 28th July 1844. Joseph Bonaparte was of a handsome figure and commanding presence; his manners were peculiarly suave and courteous. Of all the brothers he seems to have been the only one personally loved by Napoleon. His wife, the daughter of a Marseilles merchant, died on the 7th April 1845. The elder of his two daughters, Zenaide Charlotte Julie (born 1801, died 1854), was married to her cousin Charles Bonaparte, son of Lucien; the younger, Charlotte (born 1802, died 1839), was married to Napoleon Louis, second son of Louis Bonaparte.

II. Napoleon, born 1769. See Napoleon I.

III. Lucien, Prince of Canino, was born at Ajaccio, 21st March 1775. He was educated at Autun, Brienne, and Aix, and rejoined his family in Corsica in 1792. Already imbued with the principles of the Revolution he turned against Paoli when the latter declared against France, and was spokesman of the deputation sent to Marseilles to solicit aid from the republic. He did not return to Corsica, as the whole Bonaparte family soon afterwards emigrated to France, and he obtained employment in the commissariat at Saint Maximin. Here he married Mlle. Christine Boyer, of poor but good family, and began to take the leading part in the popular meetings of the place. He was elected president of the Republican committee of the town, and, by his moderation and firmness, prevented excesses such as occurred in other parts of the country. After the fall of Robespierre he was in danger of being taken for one of his partisans, but resolutely maintained his ground, and declined to take refuge in flight. In 1795 he left Saint Maximin for Saint Chamans, where he had been appointed inspector of military stores, and where he was arrested and confined for six months. His release was obtained through his brother's influence with Barras, and he retired for a time to Marseilles. In 1795 he was made commissary to the army of the north, and spent some time at Brussels and in Holland; but his heart was in the political warfare of Paris, and in 1796 he obtained permission to resign. He had a short interview with Napoleon in Italy, and spent the two succeeding years in Corsica. In 1798 he was elected deputy to the Council of Five Hundred, and at once set off for Paris. He was an ardent adherent of the constitution of 1795 (the year III.), and sympathized rather with the Abbé Sieyès than with the extreme party. His abilities were soon recognized: he was an able and powerful speaker, with a calm courage that defied all popular tumult. His house, also, was the resort of the best literary society of Paris. It gradually became clear to him that the power of the Directory was divided and broken, and that a *coup d'état* was required to prevent another sanguinary revolution. There was but one man in a position to effect this change—his brother Napoleon, whose unexpected arrival on the 10th October 1799 was received with the utmost joy. A week after, Lucien was elected president of the Council of Five Hundred. Careful preparations were made, and on the 19th Brumaire the principles of the Revolution ceased to have a living power. On that day the coolness, promptitude, and courage of Lucien alone preserved Napoleon from destruction. He took part in preparing the new scheme of government, and was appointed to succeed La Place as minister of the interior. His competency for the post was undoubted, but differences with his brother had already begun, and these were fomented by the treacherous Fouché; so that, in little more than a year, he gave up office, and was sent as ambassador to Spain. He succeeded in his negotiations, though not entirely to Napoleon's satisfaction, and after his return to Paris took an active part in the arrangement of the Concordat and the establishment of a legion of honour. After the consulate had been settled on Napoleon for life Lucien was made a senator, and received the estate of Seppelsdorf. But his marriage in 1803 with the beautiful Mme. Jouberthon was displeasing to the First Consul, who already contemplated royal alliances for his brothers. Lucien, who did not approve the project of making the consulate hereditary, thought it advisable to leave France, and settled first at Milan, but finally at Rome. He lived in great magnificence, indulging his literary tastes, and apparently indifferent to the growth of the imperial power. After the peace of Tilsit Napoleon had an interview with him, and offered him a kingdom provided he would look upon it as in all respects a province of the empire. Lucien refused, and his brother then gave him to understand that he must quit the Continent. He withdrew from Rome, and settled on the estate of Canino, whence he took his title of prince, but soon came to the resolution of sailing for America. He embarked on the 1st August 1810, was captured by an English cruiser, and was carried to England, where for some time he was kept under surveillance in Ludlow Castle. He afterwards purchased a house near London, in which he resided till 1814, when he returned to Rome. In two letters to Elba he offered assistance to his brother; and during the Hundred Days he sat in the Chamber of Peers as a French prince. After Waterloo he advised Napoleon to dissolve the assemblies and proclaim himself dictator, and it was on his recommendation that the second abdication was made in favour of Napoleon's son. All his efforts to obtain a

regency were unavailing, and soon after parting from his brother on the 29th June, he left France. Arrested at Turin he was kept for three months in confinement before he was suffered to settle again at Rome. He passed the remainder of his life in Italy, surrounded by his family and busily engaged in literary and antiquarian labours. The grounds around Canino proved unusually rich in gems and Etruscan curiosities, of which a valuable cabinet was formed. He died at Viterbo, 29th June 1840 Lucien was a man of high abilities, resolute to his purpose, and of great courage and presence of mind He was throughout his whole life a moderate or constitutional republican. As a literary man he enjoys considerable distinction, though his great epic, *Charlemagne* (2 vols. 4to, London, 1814), was a failure. His *Mémoires*, unfortunately, have not been completed. He was twice married. By his first wife he had two daughters; by his second, four daughters and four sons. Of the sons the eldest, Charles Lucien Jules Laurent (born 1803, died 1857), prince of Canino, is distinguished as a naturalist, and takes rank along with Wilson and Audubon. In 1822 he married his cousin, Zenaide, daughter of Joseph Bonaparte, whom he joined in America. He remained there till 1828, and gained high reputation by his works on American ornithology. After his return to Italy he began the publication of a magnificent work, *Iconografia della Fauna Italica*, 3 vols., 1833–41. On his father's death in 1840 he succeeded to the title, and in 1847 began to interest himself in politics. He was ordered to leave the Austrian territories for having introduced political matter into a scientific congress, and in 1848–49 he took part on the Radical side in the disturbances at Rome. Driven from that city by the arrival of French troops he landed at Marseilles, but received an order to quit French territory. Not having paid any attention to this he was seized and conducted under escort to Havre, whence he was compelled to take ship for England. He returned once more to Paris, but did not again interfere in politics. Of the other sons of Lucien, Louis Lucien (born in 1813) has distinguished himself as a philologist, and is known by his writings on the Basque language as well as on the dialects of Italy and England; and Pierre Napoleon, commonly called Prince Pierre (born 1815), has lived a troubled life of adventure in Italy, America, and France. In January 1870 he shot and mortally wounded the journalist Victor Noir, who had called upon him to arrange preliminaries for a duel with M. Paschal Grousset. This unfortunate affair did inconceivable harm to the Napoleonic cause. The prince was found not guilty, but was ordered to indemnify the family of Noir. From that time he took up his residence in London.

IV Marie Anne Elisa, born at Ajaccio on the 3d January 1777. She married in 1797 Felix Bacciochi, captain of infantry, who was poor but of good family. In 1805 Lucca and Piombino were erected into a principality for her, and she gave such proofs of administrative ability as to be named the Semiramis of Lucca. After the fall of Napoleon she lived for some time at Brunn, and latterly at Santo Andrea near Trieste, where she died in 1820.

V. Louis, the father of Napoleon III., was born at Ajaccio in 1778. He received the greater part of his military education at the school of Chalons, and accompanied his brother throughout the famous Italian campaigns. He distinguished himself in various engagements, particularly at the battle of Arcola, but manifested little enthusiasm for a military career. He took part in the Egyptian expedition, and was sent back from Cairo to report the state of affairs and solicit reinforcements. In 1802, with the greatest reluctance, for he was enamoured of another, he was prevailed on to marry Hortense Beauharnais, Josephine's daughter. The forced marriage proved exceedingly unhappy. After the consulate he became general, and in 1804 was raised to the dignity of prince. He was commissioned to organize the army of the north in 1805, and performed his task to the complete satisfaction of Napoleon. Soon afterwards the States-general of Holland sent a deputation to the emperor praying that one of his brothers might be made their king. Louis, who was selected for this dignity, consented with considerable reluctance, and was proclaimed on the 6th June 1806. But when he had assumed the reins of government he manifested the warmest interest in his new subjects. He procured the withdrawal of the French troops from Holland, and formed a cabinet consisting almost entirely of Dutch notables. The decree blockading the British Isles was extremely offensive to him in his new position, and he evaded it so far as possible. In 1807 the death of his eldest son caused him to withdraw for a time to the south of France, and on his return Hortense did not accompany him. The relations of the king with Napoleon were anything but satisfactory. The emperor complained of not receiving due assistance from Holland, and in 1809 sent Bernadotte to take command of the army in that country. At the meeting of the two brothers in December 1809 there was a bitter quarrel; and Louis, who felt that his country was looked on as merely a province of the empire, was detained as a prisoner, while Holland was overrun with French troops. Before obtaining his release he was compelled to sign a new treaty with the emperor, which greatly curtailed his power. Matters were not improved after his return to Amsterdam, and on the 1st July 1810 he abdicated at Haarlem in favour of his elder son Napoleon Louis. He then set out for Töplitz, where he resided with the assumed title of Comte de St Leu. His kingdom was soon united to the empire, and no attention was paid to the arrangement he had made. After the Russian campaign he offered his services to his brother, and tried again, but in vain, to resume his power in Holland. In 1815 he instituted proceedings against his wife to obtain from her the custody of his elder son, and gained his cause. He refused to take any part in the Hundred Days, and settled in Rome, where he passed most of the remainder of his life. His wife was reunited to him, but the death of his elder son, in 1831, was a blow from which he never recovered. The unfortunate attempts of Louis Napoleon at Strasburg and Boulogne also affected him deeply; and he in vain attempted to procure his son's liberation from the prison of Ham. After the escape of the prince his father earnestly desired to see him, but passports for Italy could not be granted. The disappointment was too much for Louis, who was seized with apoplexy, and died on the 25th July 1846. His remains were conveyed to Saint Leu in 1847. Louis was of a somewhat retiring and philosophic disposition, inclined

fond of art, and liberal. In 1810 Napoleon, although he had a great affection for her, banished her from court for her insulting behaviour to Maria Louisa. Yet she joined him in the Isle of Elba in 1814, and would fain have accompanied him in his exile at St Helena. She was reconciled to her husband shortly before her death on 9th June 1825 Pauline was Napoleon's favourite sister. She was extremely beautiful, and her statue as Venus Victrix, by Canova, is a well-known work of art.

VII. Marie Annonciade Caroline, born at Ajaccio 1782. In 1800 she was married to Murat; in 1806 she became grand-duchess of Berg and of Cleves, and in 1808 queen of Naples. In 1815, after the flight of her husband, she was compelled to leave the capital, and surrendered to the Austrians. She was for a short time imprisoned at Trieste, and was then permitted to reside at Haimburg near Vienna. She afterwards obtained leave to take up her abode at Trieste with her sister Elisa. In 1838 she obtained a pension from the French Government, but did not enjoy it long. She died on 18th May 1839.

VIII. Jérôme, the youngest brother of Napoleon, was born at Ajaccio in 1784. In 1800 he entered the navy, and served in the Mediterranean, and under Villaret Joyeuse in the West Indies. In 1802–3 he was recalled; but tne port in which his vessel lay being blockaded by the English cruisers, he made his way to Boston, whence he intended to take a passage to France. He was well received in the United States, and fell violently in love with a beautiful young American, Miss Elizabeth Paterson, daughter of a Baltimore merchant, whom he married on the 24th December 1803. He remained in America till 1805. Meanwhile Napoleon, excessively displeased, had passed a decree annulling the marriage, and declined to allow the lady to enter France Jérôme's submission was rewarded by high command in the navy, in which he showed himself a competent officer. In 1806 he was made brigadier-general in the army, and distinguished himself in Silesia. On the 8th July of the following year he was made king of Westphalia; and, on the 22d August, he married the daughter of Frederick king of Würtemberg. He accompanied Napoleon on the Russian campaign, but was disgraced for apparent want of success in some engagement, and retired to his kingdom. After the first abdication he lived for some time at Trieste, but at once rejoined the emperor in 1815, and took a conspicuous part in the hurried events of the Hundred Days. After Waterloo and the second abdication, Jérôme retired to the kingdom of his father-in-law, where he lived in a species of imprisonment. He moved afterwards to Trieste, Rome, Florence, and Lausanne, and in 1847 was permitted to visit Paris. In the following year he was made governor of the Invalides, and in 1850 marshal of France. In 1852 he was president of the senate, but after that time he took no active part in politics. He died on the 24th June 1860. Of his children the only one famous is Joseph Charles Paul, commonly known as Prince Napoleon, born in 1822.

Besides the vast mass of *mémoires* and treatises relating to the Bonaparte family, the following special works may be noted:—A. du Casse, *Mémoires et correspondance politique et militaire du Roi Joseph*, 10 vols., 1854; Miot de Melito, *Mémoires*, 3 vols., 1858; *Mémoires de Lucien Bonaparte*, 1836, 1845; *Documents historiques et réflexions sur le Gouvernement de la Hollande* (by Louis), 3 vols. 1820; Du Casse, *Mémoires du roi Jerôme*; Wouter's *Les Bonapartes depuis 1815 jusqu'à nos jours*; Jerrold, *Life of Napoleon III.*, vol. i.

BONAVENTURA. John of Fidanza, or Fidenza, more commonly known as St Bonaventura, was born at Bagnarea in the Papal States, in the year 1221. He was at an early age destined by his mother for the church, and is said to have received his cognomen of Bonaventura from St Francis of Assisi, who performed on him a miraculous cure. He entered the Franciscan order in his twenty-second year, and is said to have studied at Paris under Alexander of Hales. This does not seem very probable, but he certainly studied under Alexander's successor, John of Rochelle, to whose chair he succeeded in 1253. Three years before that period his fame had gained for him permission to read upon the *Sentences*, and in 1255 he received the degree of doctor. So high was his reputation both for brilliancy of intellect and purity of mind that, in the following year, he was elected general of his order. He at once set himself to work to introduce better discipline, and by his mild regulations succeeded in effecting much good. He was an advocate of asceticism, and looked upon the monastic life as the surest means of grace. It is worthy of notice that by his orders Roger Bacon was interdicted from lecturing at Oxford, and compelled to put himself under the surveillance of the order at Paris. Bonaventura was instrumental in procuring the election of Gregory X., who rewarded him with the titles of cardinal and bishop of Albano, and insisted on his presence at the great Council of Lyons in the year 1274. At this meeting he died. Bonaventura's character seems not unworthy of the eulogistic title, "Doctor Seraphicus," bestowed on him by his contemporaries, nor of the place assigned to him by Dante in his *Paradiso*. He was formally canonized in 1482 by Sixtus IV.

His works, as arranged in the Lyons editon (7 vols., folio), consist of expositions and sermons, filling the first three volumes; of a commentary on the *Sentences* of Lombardus, in two volumes, celebrated among mediæval theologians as incomparably the best exposition of the third part; and of minor treatises filling the remaining two volumes, and including a life of St Francis. The smaller works are the most important, and of them the best are the famous *Itinerarium Mentis ad Deum*, *Breviloquium*, *De Reductione Artium ad Theologiam*, *Soliloquium*, and *De septem itineribus æternitatis*, in which most of what is individual in his teaching is contained. In philosophy Bonaventura presents a marked contrast to his great contemporaries, Thomas Aquinas and Roger Bacon. While these may be taken as representing respectively physical science yet in its infancy, and Aristotelian scholasticism in its most perfect form, he brings before us the mystical and Platonizing mode of speculation which had already to some extent found expression in Hugo and Richard of St Victor, and in Bernard of Clairvaux. To him the purely intellectual element, though never absent, is of inferior interest when compared with the living power of the affections or the heart. He rejects the authority of Aristotle, to whose influence he ascribes much of the heretical tendency of the age, and some of whose cardinal doctrines—such as the eternity of the world—he combats vigorously. But the Platonism he received was Plato as understood by St Augustine, and as he had been handed down by the Alexandrian school and the authors of the mystical works passing under the name of Dionysius the Areopagite. Bonaventura accepts as Platonic the theory that ideas do not exist *in rerum natura*, but as thoughts of the divine mind, according to which actual things were formed; and this conception has no slight influence upon his philosophy. Like all the great scholastic doctors he starts with the discussion of the relations between reason and faith. All the sciences are but the handmaids of theology; reason can discover some of the moral truths which form the groundwork of the Christian system, but others it can only receive and apprehend through divine illumination. In order to obtain this illumination the soul must employ the proper means, which are prayer, the exercise of the virtues, whereby it is rendered fit to accept the divine light, and meditation which may rise even to ecstatic union with God. The supreme end of life is such union, union in contemplation or intellect

and in intense absorbing love; but it cannot be entirely reached in this life, and remains as a hope for futurity. The mind in contemplating God has three distinct aspects, stages, or grades,—the senses, giving empirical knowledge of what is without and discerning the traces (*vestigia*) of the divine in the world; the reason, which examines the soul itself, the image of the divine Being; and lastly, pure intellect (*intelligentia*) which, in a transcendent act, grasps the Being of the divine cause. To these three correspond the three kinds of theology,—*theologia symbolica, theologia propria*, and *theologia mystica*. Each stage is subdivided, for in contemplating the outer world we may use the senses or the imagination; we may rise to a knowledge of God *per vestigia* or *in vestigiis*. In the first case the three great properties of physical bodies—weight, number, measure,—in the second the division of created things into the classes of those that have merely physical existence, those that have life, and those that have thought, irresistibly lead us to conclude the power, wisdom, and goodness of the Triune God. So in the second stage, we may ascend to the knowledge of God, *per imaginem*, by reason, or *in imagine*, by the pure understanding (*intellectus*); in the one case the triple division—memory, understanding, and will,—in the other the Christian virtues—faith, hope, and charity—leading again to the conception of a Trinity of divine qualities—eternity, truth, and goodness. In the last stage we have first *intelligentia*, pure intellect, contemplating the essential being of God, and finding itself compelled by necessity of thought to hold absolute being as the first notion, for non-being cannot be conceived apart from being, of which it is but the privation. To this notion of absolute being, which is perfect and the greatest of all, objective existence must be ascribed. In its last and highest form of activity the mind rests in the contemplation of the infinite goodness of God, which is apprehended by means of the highest faculty, the *apex mentis*, or *synderesis*. This spark of the divine illumination is common to all forms of mysticism, but Bonaventura adds to it peculiarly Christian elements. The complete yielding up of mind and heart to God is unattainable without divine grace, and nothing renders us so fit to receive this gift as the meditative and ascetic life of the cloister. The monastic life is the best means of grace.

Bonaventura, however, is not merely a meditative thinker, whose works may form good manuals of devotion; he is a dogmatic theologian of high rank, and on all the disputed questions of scholastic thought, such as universals, matter, the principle of individualism, or the *intellectus agens*, he gives weighty and well-reasoned decisions. He agrees with Albert in regarding theology as a practical science; its truths, according to his view, are peculiarly adapted to influence the affections. He discusses very carefully the nature and meaning of the divine attributes; considers universals to be the ideal forms pre-existing in the divine mind according to which things were shaped; holds matter to be pure potentiality which receives individual being and determinateness from the formative power of God, acting according to the ideas; and finally maintains that the *intellectus agens* has no separate existence. On these and on many other points of scholastic philosophy the Seraphic Doctor exhibits a combination of subtilty and moderation which makes his works peculiarly valuable.

Editions of Bonaventura's works are numerous. The most complete early edition was that in 7 vols. fo., Rome, 1588-96. They have also been published at Lyons, 7 vols., 1668, and at Venice, 14 vols., 1751, *sqq*. The best edition is that by A. C. Peltier, begun in 1863. Of detached works the editions and translations are very numerous. The following are perhaps the most important:—*Breviloquium et Itinerarium Mentis ad Deum*, ed. Hefele, 3d ed., 1862; *Théologie Séraphique, extraite et traduite des œuvres de St B.*, by Alix, 2 vols., 1853-56. For Bonaventura's philosophy, see Erdmann, Hauréau, Stöckl; the works on the history of mysticism by Schmid, Görres, Helfferich, Noack, and Preger; and Ozanam, *Dante et la Philosophie Catholique au XIIIme Siècle*. There are two monographs on him,—Margerie (A. de), *Essai sur la philosophie de St Bonaventure*, 1855, and Hollenberg, *Studien zu Bonaventura*, 1862. Notices of his life are given in the Venice edition, and in that of Peltier; also in the *Histoire Litt. de la France*, vol. xix. (R. AD.)

BONDU, a kingdom of Western Africa lying to the W. of Bambouk, from which it is separated by the River Faleme, between 14° and 15° N. lat., and 12° and 13° W. long. The country is an elevated plateau, with hills in the southern and central parts. These are generally unproductive, and covered with stunted wood; but the lower country is fertile, and finely clothed with the baobab, the tamarind, and various valuable fruit-trees. It is traversed by beds of torrents, which flow rapidly during the rains, but are empty in the dry season. Cultivation, though it extends over only a comparatively small proportion of the whole surface, is carried on with a measure of activity. The products consist of grain (four species), rice, cotton, indigo, water-melons, cucumbers, tobacco, and fruits. The workmen in the different parts display considerable dexterity, though they employ very rude and defective tools. The people consist chiefly of Foulahs, though the country is much frequented by Mandingoes and Serawoollies for purposes of trade. The exports consist of provisions and cotton cloth manufactured in the country, and slaves and salt are imported. The caravans, bringing the former from the interior to the coast, pass usually through Bondu. The religion and laws of this country are Mahometan, though the precepts of that faith are not very rigorously observed. There are schools, however, in every town, where the Koran and the reading and writing of Arabic are taught; but the scholar is treated as the menial servant of the teacher. The king is nearly absolute, and commands a considerable body of troops, who are much employed in predatory expeditions, chiefly for the purpose of collecting slaves. His revenues are derived from a tenth part of the produce of the land, and of the salt imported, as also from duties on goods passing through his territories, with numerous presents expected or extorted. Park, who was the first European traveller to visit the country, experienced to his cost the rapacity of the reigning prince, being obliged to give up even the coat which he wore. The royal residence was then at Fatteconda; but when Major Gray visited Bondu it had been removed to Bulibani, a small town, with about 3000 of a population, surrounded by a strong clay wall. The population of the whole country is estimated at 1,500,000.

BÔNE, BONA, BOUNAH, BELED-EL-A'NEB (*the town of jujubes*), or ANNABA, a fortified town and seaport of Algeria, in the province of Constantine, 85 miles N.E. of the city of that name, on a bay of the same name at the mouth of the Seybouse, in lat. 36° 54′ N. and long. 7° 47′ E. The town is surrounded with a modern rampart erected outside of the old Arab wall, the compass of which was found too small for its growth. In other respects also it has been greatly Europeanized; much of the old town has been demolished, and the ground occupied by new buildings. The streets are wide and well laid out, but in some instances are very steep, owing to the formation of the ground. All the ordinary conveniences of a flourishing French city are met with,—bazaars, markets, coffee-houses, hotels, reading-rooms, a bank, a theatre, barracks, hospitals, an orphan asylum, and schools of various kinds. There is also a cathedral dedicated to St Augustine, as well as other Roman Catholic churches, a nunnery for sisters of mercy, handsome mosques, a synagogue, and a Protestant church. Bône is an important seat of the coral fishery, and carries on a considerable trade, the exports consisting chiefly of iron and lead ore, corn, coral, cattle and sheep, olive oil, salt fish, and tobacco. The manufactures comprise native garments,

tapestry, leather, and saddles, and of late its soap has come into repute. In 1872 there entered the port 461 French vessels, with a tonnage of 187,415 tons, and 506 foreign ships with a tonnage of 40,822. The anchorage was long insecure; but about 1870 a harbour, with an area of 195 acres, was constructed by means of two breakwaters, and an inner basin, surrounded with masonry quays, and having an extent of nearly 25 acres. The marshes at the mouth of the river have also been drained by a system of canals, to the great improvement of the sanitary condition of the town, which has the further advantage of an abundant supply of water obtained from the neighbouring hills. There are cork-woods and marble-quarries in the vicinity, and various other resources of the surrounding country are being rapidly developed. The woods, however, suffered severely from a conflagration in 1873; and it will be many years before the production of cork can become as extensive as before. The port will be rendered still more important by the railway in course of construction to various inland towns. Bône is identified with the ancient *Aphrodisium*, the seaport of *Hippo Regius* or *Ubbo*, but it derives its name from the latter city, the ruins of which, consisting principally of large cisterns, and part of the Roman walls, are still to be found about a mile to the south of the town. Hippo, the bishopric of Augustine, was burnt by the Vandals in 430, partially restored by Belisarius, and again sacked by the Arabs in the 7th century. The latter conquerors built the city of Bona, or Annaba, which has since passed through many vicissitudes. From the beginning of the 14th to the middle of the 15th century it was frequented by Italians and Spaniards, and in the 16th it was held for some time by Charles V., who strengthened its *Casbah* or citadel, originally built in 1300. From the time of Louis XIV. to the Revolution the French *Compagnie d'Afrique* maintained a very active trade with the port. The town was finally captured by the French in 1832, and its citadel was defended by a small body of marines for some months against the Turks. Population in 1872, 16,196, about half of whom are European; in 1832 it was only 3000 or 4000.

BONE, HENRY, R.A., the most eminent enamel painter of his time in Great Britain, was born at Truro in 1755. He was much employed by London jewellers for small designs in enamel, before his merits as an artist were well known to the public. In 1800 the beauty of his pieces attracted the notice of the Royal Academy, of which he was then admitted as an associate; in 1811 he was made an academician. From the beginning of the century to 1831, he executed many beautiful pieces of much larger size than had been attempted before in England; among these his eighty-five portraits of the time of Queen Elizabeth, of different sizes, from 5 by 4 to 13 by 8 inches, are most admired. They were disposed of by public sale after his death, which took place in 1834. His Bacchus and Ariadne, after Titian, painted on a plate, brought the great price of 2200 guineas.

BONFIGLI, BENEDETTO, an Italian painter, whose reputation is not equal to his importance. One of the most remarkable circumstances in the history of art in the peninsula is the sudden advance made by the school of the Umbrian province, which, until near the middle of the 15th century, was far behind those of Florence and the North, but which, in the person of Perugino and some of his followers, came into the very first rank. Criticism had been used to overlook the precursors and senior companions of Perugino, whose improvements prepared the way for his signal excellences. But among these none holds a more distinguished place than Benedetto Bonfigli. The most important of his extant works are a series, in fresco, of the life of St Louis of Toulouse, in the communal palace of his native city of Perugia. All his life (the dates of which are not quite certain) was spent in honourable employment by the civic and religious bodies of Perugia and neighbouring towns.

BONGO, a people of Central Africa, who inhabit the country lying between 6° and 8° N. lat., and 27° and 29° E. long., which is watered by five important tributaries of the Bahr-el-Ghazel. The Bongo are a brachycephalous race of medium height, with a red-brown complexion and black hair. The grain most largely cultivated by them is sorghum; but they obtain a considerable part of their food from the fruits, tubers, and fungi with which the country naturally abounds. They also eat every living creature—bird, beast, and reptile—except the dog. Tobacco is universally cultivated and smoked. They have no cotton or flax, and go for the most part with no more clothing than an ornamental girdle about the loins. The domestic animals are goats, dogs, and poultry; sheep and cattle are rare. Iron is abundant, and the people smelt and work it with great skill; it forms the only currency of the country, and is extensively employed for all kinds of useful and ornamental purposes. Their spears, knives, rings, and other articles are frequently fashioned with great artistic elaboration. They have a variety of musical instruments,—drums, stringed instruments, and horns,—in the practice of which they take great delight; and they indulge in a vocal recitative which seems intended to imitate a succession of natural sounds. Marriage is generally by purchase; and a man is allowed to acquire three wives, but not more. After marriage the women extend the under lip by the insertion of a peg of wood or bone, which is gradually increased. Tattooing is partially practised. Their method of sepulture resembles that of the Peruvians, the corpse being bound in a crouching position with the knees drawn up to the chin; and their tombs are frequently ornamented with rough wooden figures intended to represent the deceased. Of the immortality of the soul they have no notion; and their only approach to a knowledge of a deity consists in a vague idea of luck. On the other hand they have a most intense belief in a great variety of petty goblins and witches, which are identified with bats, owls, and other ominous animals. Their language is musical, and abounds in the vowels *o* and *a*; its vocabulary of concrete terms is very rich, but the same word has often great variety of meanings. The grammatical structure is simple. The Bongo are now subject to the people of Khartoom, who have treated them with great injustice, and greatly reduced the numbers of the population, which now hardly exceeds 100,000.

BONI, a kingdom or confederation in the island of Celebes, stretching along a part of the western shores of a great bay of the same name, which indents the south side of the island to the depth of nearly 180 miles. It has an area of 450 square miles at most, and its present population is estimated about 200,000. It was at one time the most powerful state of Celebes, all the other princes being regarded as vassals of its king, but has latterly been practically reduced to a Dutch dependency, though this has not been brought about without trouble. An expedition in 1825, under General van Geen, was not very successful; but the war of 1859 was brought to a more satisfactory termination for the invaders. The inhabitants, called Bugis, are one of the most remarkable of the peoples of the Eastern Archipelago. They speak a language allied to that of the Macassars, and write it with similar characters. It has been studied and its letters reproduced in type by Dr B. F. Matthes of the Netherlands Bible Society. The Bugis are industrious and ingenious; they practise agriculture more extensively than the neighbouring tribes, and manufacture cotton cloth not only for their own use, but also

for export. They likewise carry on a considerable traffic in the mineral and vegetable productions of their country, such as gold dust, tortoise-shell, pearls, nutmegs, camphor, and various medicinal preparations. Their towns are regularly built, and they have schools of their own. The king is elected generally for life, and always from their own number, by the chiefs of the eight petty states that compose the confederation, and he cannot decide upon any public measure without their consent. In some of the states the office of chief is hereditary; in others any member of the privileged classes may aspire to the dignity, and it not unfrequently happens that the state comes to be governed by a woman. The capital, also called Boni, is situated on the coast in 4° 37′ S. lat. and 120° 30′ E. long., and is the residence of the king. Various Dutch settlements have been formed round the bay. Of the history of Boni not much is known. According to Temminck, it first acquired importance in the year 1666, when the rajah Palakkah, whose father and grandfather had been murdered by the family of Hassan, the tyrant of Sumatra, made common cause with the Dutch against that despot. From that date till the beginning of the present century the Dutch influence in the kingdom remained undisputed. In 1814, however, Boni fell into the hands of the British, who retained it for two years; but by the European treaties concluded on the downfall of Napoleon it reverted to its original colonizers. See CELEBES.

BONIFACE, ST, the Apostle of Germany, whose real name was Winfrid, was born at Crediton in Devonshire, in 680. He was of good family, and it was somewhat against his father's wishes that he devoted himself at an early age to the monastic life. He received his theological training in the convents of Exeter and Nutcell, and at the age of thirty became a priest. In 715 he set out on a missionary expedition to Friesland, but his efforts were frustrated by the war then being carried on between Charles Martel and Radbod, king of the Frisians. Despite the wishes of his brethren, who desired to make him their abbot, he again set out in 718, visited Rome, and was commissioned by Gregory II. to preach to the pagans of Germany. For five years he laboured in Thuringia, Hessia, and Friesland, and then returned to Rome to report his success. He again set out for Germany, and, armed with full powers from the Pope, baptized thousands of the heathen, and brought back to the Church of Rome many Christians who had in a measure separated themselves from the fold. After another visit to Rome in 738 he proceeded to Bavaria, and founded there the bishoprics of Salzburg, Regensburg (Ratisbon), Freisingen, and Passau. He then resumed his labours in Germany, where he erected the districts of Würzburg, Erfurt, and Burburg into bishoprics. He also organized provincial synods in the Frankish Church, and obtained great influence over the king, Pepin, whom he crowned at Soissons. Boniface had been created a bishop by Gregory II., and after the deposition of the bishop of Mainz in 745, that bishopric was converted into a metropolis and conferred upon him, much against his own inclinations. He had never relinquished his hope of converting the Frisians, and in 755 he set out with a small retinue for Friesland. He baptized a great number, and summoned a general meeting for confirmation at a place not far from Dokkum, between Franeker and Groningen. Instead of his converts, however, there appeared a mob of armed pagans, who fell upon the aged archbishop and slew him. His remains were finally deposited in the famous abbey of Fulda, founded by himself.

The epistles of Boniface have been published by Serrarius, 1605, and by Würdtwein, 1790; his works by Giles, 2 vols., 1842. On his life and labours see Löffler, *Bonifacius*, 1812; Seiter, *Bonifacius*, 1845; Rettberg, *Kirchengeschichte Deutschlands*, i.; Neander, *Church History*, Bohn's transl., vol. v.

BONIFACE, the name of nine popes.

BONIFACE I., bishop of Rome from 418 to 422, was a contemporary of St Augustine, who dedicated to him some of his works.

BONIFACE II., 530–532, was by birth a Goth, and owed his election to the influence of the Gothic king. He had for some time an anti-pope, Dioscurus.

BONIFACE III., 15th February to 12th November 606, obtained from Phocas recognition of the headship of the Church at Rome.

BONIFACE IV., 608–615, received from Phocas the Pantheon at Rome, which was converted into a Christian church.

BONIFACE V., 619–625, did much for the Christianizing of England.

BONIFACE VI. was elected in April 897, and died fifteen days afterwards.

BONIFACE VII., who attained the Papal chair in 974, is sometimes styled an anti-pope. He is supposed to have put his predecessor, Benedict VI., to death. A popular tumult compelled him to flee to Constantinople; but he carried with him vast treasure, and in 984 he returned and removed, by murder, John XIV., who had been elected in his room. He died in 985 or 986.

BONIFACE VIII., Benedict Cajetan, a man of great ability, was elected in 1294, Celestine V. having been persuaded to resign. He meddled incessantly in foreign affairs, and put forward the strongest claims to temporal as well as spiritual supremacy. His bitterest quarrels were with the emperor, with the powerful family of the Colonnas, and with Philip the Fair of France, whom he excommunicated in 1303. He was about to lay all France under an interdict when he was seized at Agnani by a party of horsemen under Nogaret, an agent of Philip, and Sciarra Colonna. After three days' captivity he was rescued by the town's people, but the agitation he had undergone caused his death soon after, on the 11th October 1303. In 1300 Boniface instituted the *jubilees*, which afterwards became such a source of profit and of scandal to the church.

BONIFACE IX. was elected in 1390 and died in 1404. During his time the so-called Clement V. continued to hold state as pope in Avignon.

BONIFACIO, a town at the southern extremity of Corsica, in the arrondissement of Sartene, near the strait to which it gives its name. It is one of the most picturesque and interesting places in the island, its white houses being built on the top of a white calcareous rock that can only be reached on foot or on horseback. It is well fortified, has a secure harbour, carries on some trade, and has coral fisheries. The rock is hollowed out into vast caves that stretch below the town. Bonifacio was founded in 833 by the Tuscan Marquis whose name it bears, as a defence against the Saracen pirates. At the end of the 11th century it became subject to Pisa, and in 1195 was taken by the Genoese, whose influence continues to affect the character of the population to this day. In 1421 it heroically withstood a protracted siege by Alphonso of Aragon; but in 1553 it fell into the hands of the Franco-Turkish army. Population in 1872, 3402. (See Gregorovius's *Corsica*, vol. ii.; Lear, *Journ. in Corsica*, p. 62.)

BONN, the chief town of a circle of Rhenish Prussia, situated on the left bank of the Rhine, about 16 miles by rail S.S.E. of Cologne. The central part is mostly composed of very narrow streets, but the outskirts contain numerous fine buildings, and the general appearance from the river is rather attractive. There are five Roman Catholic and two Protestant churches, the most important of which is the Minster or St Cassius, an old building in

the Transition style, surmounted by five towers. The town also possesses a "Rathhaus," of modern erection, a court-house, a hospital, a gymnasium, and a theatre. By far the finest of its buildings, however, is its famous university, which occupies the larger part of the southern frontage of the town. The present establishment only dates from 1818, and owes its existence to the king of Prussia; but as early as 1786 the academy which had been founded about nine years before was raised by Archbishop Maximilian Frederick of Cologne to the rank of a university, and continued to exercise its functions till 1794, when it was dissolved by the last elector. The building now occupied was originally the electoral palace, constructed about 1717 out of the materials of the old fortifications. It was remodelled after the town came into Prussian possession. There are five faculties in the university—a legal, a medical, and a philosophic, and one of Catholic and another of Protestant theology; in 1873 it was attended by 752 students, ranking as eighth among the German universities. The library numbers upwards of 200,000 volumes; and the antiquarian museum contains a valuable collection of Roman relics discovered in the neighbourhood. A separate building for anatomical operations is situated in the extensive garden to the south of the university; and an academy of agriculture, with a natural history museum and botanic garden attached, is established in the palace of Clemensruhe at Poppelsdorf, which is reached by a fine avenue about a mile long, bordered on both sides by a double row of chestnut trees. A splendid observatory, long under the charge of Argelander, stands on the south side of the road. Among the numerous men of learning who have taught or teach in Bonn are the theologians Bleek and Lange, Hermes and Achterfeldt; the jurists Walter and Böcking; Harless, Mayer, and Rindfleisch in the medical faculty; and Niebuhr, Welcker, Ritschl, Brandis, Lassen, Simrock, Diez, and Sybel, in various branches of literature and history. Beethoven was born in the town, and a statue was erected to him in the Münsterplatz in 1845. Niebuhr is buried in the cemetery outside of the Sternthor, where a monument was placed to his memory by Frederick William IV. But for its university Bonn would be a place of comparatively little importance, its industry and commerce being of moderate dimensions. Its principal manufactures are cotton and silk, earthenware, soap, vitriol, and tobacco; and its trade, chiefly carried on by the Rhine, consists largely of corn and wine. Population in 1871, 26,030. Bonn (*Bonna* or *Castra Bonnensia*), originally a town of the Ubii, became at an early period the site of a Roman military settlement, and as such is frequently mentioned by Tacitus. It was the scene, in 70 A.D., of a battle, in which the Romans were defeated by Claudius Civilis, the valiant leader of the Batavians. Greatly reduced by successive barbarian inroads it was restored about 359 by the Emperor Julian, but its importance only dates from 1268, when it became the residence of the electors of Cologne. During the various wars that devastated Germany in the 16th, 17th, and 18th centuries, the town was frequently besieged and occupied by the several belligerents, but continued to belong to the electors till 1794, when the French took possession of it. At the peace of Lunéville they were formally recognized in their occupation; but by the Vienna Congress of 1814 the town was made over to Prussia. The fortifications had been dismantled in 1717.

BONNER, or BONER, EDMUND, an English prelate, notorious for his persecutions of the Protestants during the reign of Queen Mary, was born at Hanley in Worcestershire, about the end of the 15th century, and generally passed for the natural son of George Savage, a priest who was the natural son of Sir John Savage of Clifton in the same county. Strype in his *Memorials of Cranmer*, however, says he was positively assured that Bonner was the legitimate offspring of a poor man, who lived in a cottage long afterwards known as Boner's place. About 1512 he entered as a student of Broadgate Hall (now Pembroke College), Oxford; and in 1519 he was admitted as bachelor of the canon and of the civil law. Having been admitted into orders, he obtained some preferment in the diocese of Worcester. In 1525 he took his degree as doctor, and attracted the notice and patronage of Wolsey. Bonner was with the cardinal at Cawood when he was arrested on charge of high treason. After the death of Wolsey he adopted Lutheran sentiments, and insinuated himself into the favour of Henry VIII., who made him one of his chaplains, and employed him in several embassies abroad. In 1532 he was sent to Rome with Sir Edward Carne, to answer for the king, who had been cited to appear in person or by proxy in regard to the divorce of Queen Catharine. In 1533, being again despatched to Pope Clement VII., then at Marseilles, to intimate Henry's appeal to a future general council from the sentence pronounced against his divorce, he threatened the Pope with so much resolution, that his holiness talked of having him burned alive or thrown into a cauldron of melted lead. Clement did not foresee that the man whom he had thus menaced with the flames was destined to burn heretics in England in support of the very faith which, under Henry, he had lent his aid to overthrow. In 1538, being then ambassador at the court of France, he was nominated bishop of Hereford; but before consecration, he was translated to the see of London, and was enthroned in April 1540. When Henry VIII. died in 1547, Bonner was ambassador at the court of the Emperor Charles V. During Henry's reign he was constantly zealous in his opposition to the Pope, and favoured the Reformation in obedience to the king, who exacted rigid compliance with all his caprices. On the accession of Edward, however, Bonner refused to take the oath of supremacy, and was committed to the Fleet, where he remained until he promised obedience to the laws. After his release he assented to the Reformation, but with such manifest reluctance, that he was twice reprimanded by the Privy Council, and in 1549 was, after a long trial, committed to the Marshalsea, and deprived of his bishopric, to which, however, he was restored on the accession of Mary; and soon afterwards he was appointed, in place of Cranmer, vicegerent and president of the Convocation. From this time he became the chief instrument of persecution, and is said to have condemned no less than 200 Protestants to the flames in the space of three years. On the accession of Elizabeth he appeared with the rest of the bishops at Highgate, to congratulate her; but the queen refused to permit him to kiss her hand. Having, in the second year of her reign, refused to take the oath of supremacy, he was again committed to the Marshalsea, where he died, September 5, 1569, after a confinement of ten years. The character of Bonner was remarkable for obstinacy and inflexibility in everything save principle; yet even in this respect it exhibits some striking contrasts. In his early career he accommodated his principles to his convenience and ambition; after his return to Catholicism, he remained steadfast to the church, and, when disgraced, bore his deprivation and imprisonment with apparent resignation. The charge of atheism brought against one so defiled with blood was superfluous. He was constitutionally merciless and austere, fitted by nature for a persecutor, and equally capable of employing the same ardent zeal either against or in favour of any cause that he espoused. Among his works are, *Responsum et Exhortatio in Laudem Sacerdotii*,

a preface in Gardener's treatise *De Vera Obedientia*, and several homilies.

BONNET, Charles, an eminent naturalist and philosophical writer, was born at Geneva on the 13th March 1720. The Bonnets, a French family whom the religious persecution in the 16th century had driven into Switzerland, were accustomed to fill important posts in the Genevese Government; and young Charles Bonnet was expected to qualify himself to make use of the family influence by becoming a lawyer. But dry legal technicalities proved to be anything but attractive to his rich and imaginative mind, all the more that he found in the study of nature an employment which was not also a task. He made law his profession, but he never seems to have permitted it to interfere seriously with his favourite pursuits. The account of the ant-lion in Pluche's *Spectacle de la Nature*, which he chanced to read in his sixteenth year, turned his attention in particular to the wonders of insect life. He procured Réaumur's work on insects, and with the help of live specimens succeeded, after minute and patient investigation, in adding many observations to those of Réaumur and Pluche. The result of two years' labour he made known to Réaumur, who was naturally not a little surprised to find so much sagacity and power of research in a youth of eighteen. In 1740 Bonnet communicated to the Academy of Sciences a paper containing a series of experiments establishing what is now termed parthenogenesis in *aphides* or tree-lice, which obtained for him the honour of being admitted a corresponding member of the academy. In 1741 he instituted a set of experiments respecting the reproduction of worms by fission; and in the following year he discovered that the respiration of caterpillars and butterflies is performed by pores, to which the name of *stigmata* has since been given. In 1743 he was admitted a fellow of the Royal Society; and in the same year he became a doctor of laws,—his last act in connection with a profession which had ever been distasteful to him. His first published work appeared in 1745, entitled *Traité d'Insectologie*, in which were collected his various discoveries regarding insects, along with a preface on the development of germs and the scale of organized beings. Botany, particularly the leaves of plants, next attracted the attention of Bonnet; and after several years of diligent study, rendered irksome by the increasing weakness of his eyesight, he published, in 1754 one of the most original and interesting of his works, *Traité de l'usage des feuilles*; in which among other things he advances many considerations tending to show that plants are endowed with powers of sensation and discernment. But Bonnet's eyesight, which threatened to fail altogether, now caused him to turn his thoughts from investigation to speculation. In 1754 his *Essai de Psychologie* was published anonymously in London. This was followed in 1760 by the *Essai analytique sur les facultés de l'âme*, in which he develops his views regarding the physiological conditions of mental activity. He returned to physical science, but to the speculative side of it, in his *Considérations sur les corps organisés*, Amsterdam, 1762. The principal objects of this work were to give, in an abridged form, all the most interesting and well-ascertained facts respecting the origin, development, and reproduction of organized bodies, to refute the theory of *epigenesis*, and to explain and defend the doctrine of pre-existent germs. In his *Contemplation de la Nature*, which next appeared (1764–5), one of his most popular and delightful works, he sets forth, in eloquent language, the theory that all the beings in nature form a gradual scale rising from lowest to highest, without any break in its continuity. His last important work is entitled *Palingénésie Philosophique*, (Geneva, 1769); in it he treats of the past and future of living beings, and supports the idea of the survival of all animals, and the perfecting of their faculties in a future state. Bonnet's life was singularly uneventful. He seems never to have passed beyond the limits of his native country; nor does he appear to have taken any part in public affairs except for the comparatively short period between 1752 to 1768, during which he was a member of the council of the republic. The last twenty-five years of his life he spent in the country, simple and regular in his mode of life, easy in his circumstances, and happy in a small circle of friends. His wife, whom he married in 1756, was a lady of the family of De la Rive. They had no children, but Madame Bonnet's nephew, the celebrated De Saussure, was brought up as their son. Bonnet died, after a long and painful illness, on the 20th May 1793.

The outlines of Bonnet's philosophical system may be set forth in a few sentences. Man, according to him, is a mixed being, composed of two distinct substances,—mind and body,—the one immaterial and the other material. In what manner the two are connected we do not know, but of this at least we are certain, that bodily activity is a necessary condition of thought. All knowledge originates in sensations; sensations themselves follow (but whether as physical effects or merely as sequents Bonnet will not say) vibrations in the various nerves appropriate to each; and lastly, the nerves are made to vibrate by the action of outward objects upon them. A nerve once set in motion by a particular object contracts a certain tendency to reproduce that motion; so that when it a second time receives an impression from the same object it vibrates with less resistance. It is the sensation accompanying this increased flexibility in the nerve that is, according to Bonnet, the condition of memory. When reflection—that is, the active as distinguished from the merely passive element in mind—is applied to the acquisition and combination of sensations, those abstract ideas are formed which are usually placed in opposition to sensations, but which are thus, no matter how refined they may appear, sensations in combination only. That which puts the mind into activity is pleasure or pain; happiness is the end of human existence. Bonnet's metaphysical theory is based on two principles borrowed from Leibnitz,—first, that there are not successive acts of creation, but that the universe is completed by the original act of the divine will, and thereafter moves on by its own inherent force; and, secondly, that there is no gap in the continuity of existence. The divine Being, according to Bonnet, originally created a multitude of germs in a graduated scale, each with an inherent power of self-development. At every successive step in the progress of the globe, these germs, or what has been developed in their place, advance nearer to perfection; if some advanced and others did not there would be a gap in the continuity of the chain. Thus not man only but all other forms of existence are immortal. Nor is it man's mind merely; his body also will pass into the higher stage, not, indeed, the body he now possesses, but a finer one of which the germ at present exists within him. This is equally true of the other animals, who also possess a germ that will develop itself in the next stage; and every individual begins each successive stage with that amount of perfection and of knowledge which he had when he left the previous stage. It is impossible, however, to reach absolute perfection, because the distance is infinite. It is difficult to reconcile this last proposition with the law of continuity, if that law is to be accepted, as Bonnet seems to accept it, as an absolute principle of the universe, embracing all existence divine and created, for surely the interval between the divine Being and the highest created being, constantly lessening though it be, is a break in the continuity of the chain. It is also difficult to understand whether the constant advance to perfection is performed by every individual on his own account, or only by each race of beings as a

whole. Is a man when he dies at once translated to the next stage, or must he wait until the time comes when the advancement of the whole human race takes place, before he, at any rate consciously, realizes the new state? There seem, in fact, to be two distinct but somewhat analogous doctrines,—that of the constantly increasing advancement of the individual in future stages of existence, and that of the constantly increasing advancement of the race as a whole according to the successive evolutions of the globe.

Bonnet's complete works appeared at Neufchatel in 1779-1785, partly revised by himself. An English translation of certain portions of the *Palingénésie Philosophique* was published in 1787, under the title, *Philosophical and Critical Inquiries concerning Christianity*. (See A. Lemoine, *Charles Bonnet*, Paris, 1850; and the Duc de Caraman's *Charles Bonnet, philosophe et naturaliste*, Paris, 1859.)

BONNEVAL, Claude Alexandre, Comte de, a celebrated French adventurer, known also as Achmet Pasha, was the descendant of an old family of Limousin. He was born on the 14th July 1675 at Coussac, and at the age of thirteen joined the Royal Marine Corps. After three years he entered the Guards, whence he was transferred to the infantry regiment of Latour He served in the Italian campaigns under Catinat, Villeroi, and Vendôme, and in the Netherlands under Luxembourg, giving proofs of indomitable courage and great military ability. His insolent bearing towards Chamillard, minister of war, was made matter for a court-martial. He was condemned to death, but having foreseen this sentence, he saved himself by flight to Germany. Through the influence of Prince Eugene he obtained a command in the Austrian army, and fought with great bravery and distinction against France, and afterwards against Turkey. He was severely wounded at Peterwardein, and after his recovery paid a visit to Paris. The proceedings against him in France had been allowed to drop, and he married a daughter of Marshal de Biron, whom, however, he deserted after a week or two. He returned again to the Austrian army, and fought with distinction at Belgrade. He might now have risen to the highest rank, had he not made himself disagreeable to Prince Eugene, who sent him as master of the ordnance to the Low Countries There his ungovernable temper led him into a quarrel with the Marquis de Prié, governor of the Netherlands, who answered his challenge by placing him in confinement. A court-martial was again held upon him, and he was condemned to death; but the emperor commuted the sentence to one year's imprisonment and banishment from the imperial domains. Bonneval, soon after his release, offered his services to the Turkish Government, professed the Mahometan faith, and took the name of Achmet. He was made a pasha of three tails, and appointed to the command of the artillery. He rendered valuable sevices to the sultan in his war with Russia, and with the famous Kouli Khan. As a reward he received the governorship of Chios, but soon fell under the suspicion of the Porte, and was banished for a time to the shores of the Black Sea. He was meditating a return to Europe and Christianity when he died at Constantinople, 27th March 1747. The *Memoirs* published under his name are spurious. (See Prince de Ligne, *Mémoire sur la Comte de Bonneval*, 1817.)

prisoned for two years at Grolée. On his liberation he returned to his priory. In 1530, when travelling in the service of the republic, he was unfortunate enough to fall into the hands of robbers, who delivered him over once more to the duke of Savoy. His imprisonment in the castle of Chillon, which has been celebrated in Byron's poem, lasted till 1536, when he was liberated by the combined force of the Bernese and Genevese. On his return to Geneva, which had now completely emancipated itself, he received the honours and rewards that were due to his patriotism, being made a member of the Council of Two Hundred, and endowed with a pension. He died about 1570, the precise date being uncertain. Bonnivard was the author of a history of Geneva, and left his books and manuscripts to the town.

BONPLAND, Aimé, French traveller and botanist, was born at Rochelle, August 22, 1773. After serving as a surgeon in the French navy and studying under Corvisart at Paris, he accompanied Humboldt during five years of travel in Mexico, Colombia, and the districts bordering on the Orinoco and Amazon. In these explorations Bonpland collected and classified about 6000 plants till then mostly unknown in Europe, which he afterwards described in *Plantes Equinoxiales*, &c. (Paris, 1808-1816). On returning to Paris he received a pension and the superintendence of the gardens at Malmaison, became acquainted with Gay-Lussac, Arago, and other eminent scientists, and published *Monographie des Mélastomées* (1806), and *Description des plantes rares de Navarre*. After vainly endeavouring to persuade Napoleon to retire to America, he set out, in 1816, with various European plants for Buenos Ayres, where he was elected professor of natural history, an office which he soon quitted in order to explore Central South America. While journeying to Bolivia he was arrested as a spy, in 1821, by command of Dr Francia, who detained him a prisoner at Santa Marta until 1831, during which time he acted with great disinterestedness as a physician to the neighbouring poor. On regaining liberty he resided at San Borje in the province of Corrientes, until his removal in 1853 to Santa Anna, where he occupied himself in scientific research, and in cultivating the orange trees which he had introduced. He was widely respected, and was presented with an estate worth 10,000 piastres by the Government of Corrientes. His intention of revisiting Paris was frustrated by his death at Santa Anna in 1858. (See Humboldt's *Travels*.)

BONSTETTEN, Charles Victor de, was born at Bern in 1745, of a noble and ancient family. He received the elements of his education in his native town, and at fourteen was sent to Yverdun, and soon after to Geneva. There he imbibed many revolutionary doctrines both in religion and politics, which ill fitted him for a career as a Bernese senator of the traditional type; and his father, alarmed at the tone of his son's letters, peremptorily ordered him to return home—a command which the young man, albeit he would acknowledge no authority but reason, was obliged to obey. The change, however, was worse than useless; for the dulness of Bern so preyed upon his mind that he made an attempt on his life, which was frustrated by the somewhat curious accident of a ray of the moon attracting his attention when about to discharge the pistol. His father seeing his condition, sent him to Leyden to finish his studies; but as the climate of the place disagreed with him, he was allowed to exchange it for England, which he reached in 1769. The facility with which he gathered friends around him, which distinguished him, perhaps, as much as anything else, made his stay in England not the least happy period of his life. He went home by way of Paris, where he was introduced to much of the best literary society in France, but on his return

he found that the mournful duty awaited him of nursing his father in his last illness. Immediately after his father's death he again left home, and spent a considerable time in Italy, travelling as far south as Naples. Time and experience had done much to alter the character of Bonstetten since the days of his wild theorizings at Geneva. No longer a Republican, but still a Liberal, he was daily recognizing with greater clearness that the watchwords of revolution meant anything but law and order. On returning to Bern he became a member of the avoyer's council, and soon after was appointed magistrate at Gessenay. Thence he was removed in 1787 to Nyon in the Pays de Vaud, a place attractive to him from its proximity to the intellectual life and society of Geneva and Lausanne, but in other respects unsuitable; for the Pays de Vaud, as well from its nearness to France and to Geneva, as from the weight of the Bernese yoke, was nearly ripe for revolt, and Bonstetten was, as a magistrate, trusted neither by his revolutionary friends and former allies, nor by his fellow-rulers in the government of Bern. He firmly declared that he should stand by his order, a declaration that was not without good effects; but in 1792, when Geneva was threatened by the army of the Convention, he took certain steps to avert the danger, which, as he had not received a military training, were not very judicious. This increased the suspicion which the Bernese Government felt towards him; and, in consequence, he was permitted to exchange his office for one on the Ticino, where he remained until 1797, when political troubles and the French armies compelled him to leave his native country. At the solicitation of Madame Brün he at first repaired to Copenhagen, but he finally determined to settle at Geneva, which proved to be his home for the rest of his life. There, as of old, he enjoyed the society of many distinguished persons; but if this last half of his life is the most brilliant, it is also the least eventful. He died in February 1832.

As a writer Bonstetten cannot be said to occupy a very high place. His works, indeed, show a great power of observation, and an extensive insight into human character; but as a psychologist he is deficient in method, exactness, and depth; and his style, like his thought, wants point and clearness. In psychology he occupies an eclectic position, and urges the necessity of making use of internal observation in the study of mind. It is, however, in his social character, as a conversationalist, and as the friend, often the intimate companion, of many of the leaders of thought and action during his long life, that Bonstetten will be best remembered. The following are the titles of his chief works:—*Recherches sur la nature et les lois de l'imagination*, 1807; *Etudes d'homme, ou Recherches sur les facultés de sentir et de penser*, 1821; *Sur l'éducation nationale*, 1802; *Pensées sur divers objets de bien public*, 1815; *L'Homme du Midi et l'Homme du Nord*, 1814.

BONVICINO, Alessandro. See Moretto.

BOOK, the common name for any literary production of bulk, now applied particularly to a printed composition forming a volume. The name is also used for the literary divisions of a work.

Wachter, with some other writers, derives the word from the same root as the German *biegen*, to bend, as the Latin *volumen* comes from *volvere*. But the more common etymology makes the tree the parent of the book, and refers the origin of the latter (Angl. Sax., *boc;* Germ., *Buch;* Dutch, *boek*) to writing on the bark of the beech tree (Angl. Sax., *boc;* Germ., *Buche;* Icel., *beyke;* Dutch, *beuke*), or perhaps on beach boards. Analogy supports this derivation. The *byblos* of the Greeks—whence their name for a book—refers to the Egyptian papyrus itself, and the Latin *liber* to the pellicle which enclosed its stalk. The *codex* of the Romans meant at first the trunk of a tree; and the *leaves* of a book indicate a similar origin.

The earliest writings were purely monumental, and accordingly those materials were chosen which were supposed to last the longest. The same idea of perpetuity which in architecture found its most striking exposition in the pyramids was repeated, in the case of literary records, in the two columns mentioned by Josephus, the one of stone and the other of brick, on which the children of Seth wrote their inventions and astronomical discoveries; in the pillars in Crete on which, according to Porphyry, the ceremonies of the Corybantes were inscribed; in the leaden tablets containing the works of Hesiod, deposited in the temple of the Muses, in Bœotia; in the ten commandments on stone delivered to Moses; and in the laws of Solon, inscribed on planks of wood. The notion of a literary production surviving the destruction of the materials on which it was first written—the "monumentum ære perennius" of Horace's ambition—was unknown before the discovery of substances for systematic transcription.

Tablets (*tabulæ*) of ivory or metal were in common use Tablets. among the Greeks and Romans. When made of wood—sometimes of citron, but usually of beech or fir—their inner sides were coated with wax, on which the letters were traced with a pointed pen or stiletto (*stylus*), one end of which was used for erasure. It was with his *stylus* that Cæsar stabbed Casca in the arm when attacked by his murderers. Two such tablets, joined together, were called *diptycha*,[1] the earliest specimens of bookbinding. They were fastened together at the back by wires, which acted as hinges; the pages were called *ceræ*, from their waxen coating, and a raised margin was left round each to prevent obliteration by friction. Wax tablets of this kind continued in partial use in Europe during the Middle Ages; the oldest extant specimen, now in the museum at Florence, belongs to the year 1301. The leaves of the palm tree were afterwards used in their stead, as also the inner bark of the lime, the ash, the maple, and the elm. But the earliest, though long obsolete, flexible material of importance was Papyrus. made from the concentric coats which wrapped the stalk of the Egyptian *papyrus*, from which is derived our word *paper*. The time of its introduction has been much disputed; but it was certainly known long before Herodotus. The length of the Greek papyri is said to vary from eight to twelve inches; the Latin often reach sixteen. Some rolls, however, have been found as long as thirty feet. They were written on with reeds dipped in gum-water coloured with charcoal or soot of resin, the writing being readily obliterated with a sponge; and it is conjectured that the surface was sometimes prepared for that purpose with a wash or varnish. Pliny mentions also the ink of the cuttle fish as having been used for writing, as well as a decoction of the lees of wine.[2] Red ink consisted of a preparation from cinnabar. The next material commonly employed after papyrus was parchment, made from the skins of animals, usually of Parchm sheep or lambs. Vellum is a finer substance, consisting of prepared calf-skin. Parchment is commonly ascribed to Eumenes, king of Pergamus, in Asia Minor; but he was, in all probability, not the inventor but the improver. Writing on skins is mentioned by Herodotus as common in his day; and Diodorus and Ctesias speak of ancient Persian records on leather. The word itself (*pergamena*) first occurs, according to Mabillon, in the writings of Tatto, a monk of the 4th century. It appears to have superseded papyrus about the 7th century; but its quality afterwards

---

[1] See Montfaucon, *Pal. Græc.* p. 34. There are several specimens in the British Museum.

[2] For more on this subject see Caneparius, *De Atramentis cujuscunque generis*, London, 1660; Beckmann's *History of Inventions*; and Becker's *Charicles* and *Gallus*.

deteriorated. At first only one side was written on, the back being frequently stained. Parchments written on both sides are called by Pliny *opisthographi*. The term *boc-fell* is found, in early English, to designate this material. Its dearness in classical times led to the practice of erasing the original writing for the purpose of substituting new. Parchments so obliterated are known as *palimpsests*, from a Greek word signifying twice rubbed, or prepared for writing; and they are alluded to under that name by Cicero (*ad Div.* vii. 18). Paper. Paper made from cotton (*charta bombycina*) came into use, according to Montfaucon, towards the end of the 9th or the beginning of the 10th century; and the invention was opportune, as it checked the further use of palimpsests, which, from the scarcity of parchment and the demand for books of devotion, had imperilled the preservation of much classical literature. Cicero's *De Republica* was discovered by Angelo Mai in the Vatican library written under a commentary of St Augustine on the Psalms; and the Institutions of Gaius, in the library of the chapter at Verona, were deciphered in like manner under the works of St Jerome. But the invention of linen paper gave the first real impulse to book production. The precise date of this invention is disputed; Mabillon refers it to the 12th century. Montfaucon, however, found no specimens earlier than 1270, and Maffei none before 1300; the most numerous of them belong to the 14th century. Scaliger ascribes the invention to the Germans, Maffei to the Italians, and others to certain Greek refugees at Basel; while Duhalde refers it to the Chinese, and Prideaux to the Saracens in Spain. For further particulars respecting the various substances of early books, the reader may consult the first volume of the *Nouveau traité de diplomatique*, by the Benedictines of St Maur, and the *Essai sur l'histoire du Parchemin et du Vélin*, by Peignot, who has given a list of authorities on this subject.

Rolls. The form of ancient books differed with the materials of which they were composed. When flexible matter came into use, it was found convenient to make books in the form of rolls, and the two names are synonymous in legal phraseology to this day. The papyrus, and afterwards the parchment, was joined together to form one sheet, and then rolled upon a staff into a volume (*volumen*). When an author divided his work into portions or "books," in the literary sense of the word, each division was usually a *volumen* by itself,—thus Ovid speaks of his fifteen books of the *Metamorphoses* as so many *volumina*; and the same was done when an entire work was too bulky to be rolled on one stick. The staff in the Herculaneum rolls is concealed by the papyrus, but it usually projected, the ends being ornamented with bosses (*umbilici*) of wood and ivory. The title (*titulus index*) was either suspended like a ticket to the roll, or pasted on the outside. These rolls were frequently protected by a parchment cover; they were deposited in a cylindrical box (*capsa* or *scrinium*), or were arranged horizontally in cases round the walls of a library, as at Herculaneum. Many books could probably be stowed away in small compass by this means; and the smallness of the rooms devoted in ancient times to such collections is readily explained in this manner. The *volumen*, however, in most cases, was far from containing as much as our ordinary books, even in an octavo form. The square form, originally applied to the *codices* or wax tablets joined together in the way described above, was resorted to afterwards for separate leaves, the same name being retained with altered materials. Martial speaks of this later kind of *codex* as a novelty in his day. It was common, however, in Greek MSS., among the earliest of which Montfaucon discovered few specimens of rolls. The term *liber* in the 4th century is found applied to both rolls and squared leaves, but the former were discontinued in the Middle Ages, and covers of boards were gradually introduced, the leaves being stitched together as well as folded.

The internal arrangement of books has undergone many modifications, which belong, however, chiefly to the subject of early writing. At first the letters were divided only into lines, then into separate words, and these by degrees were noted with accents, and distributed by points and stops into periods, paragraphs, chapters, and other divisions. In some countries, as among the Orientals, the direction of the characters was from right to left, in others, as among the Northern and Western nations, from left to right. The early Greeks followed the two directions alternately,—a method which was called *boustrophedon*, from its analogy to the path of oxen when ploughing. In most countries the lines run from side to side, but in some, particularly among the Chinese, their direction is vertical. Internal arrangements.

The diffusion of early books concerns especially the literary historian. Their scarcity before printing is illustrated by the conditions attached to purchase or loan; but it must be remembered that a particular book might easily bear a monopoly price, and that this is no test of the cost of those which might be multiplied by transcription. When, however, the small number of copyists in the Dark Ages and even later is considered, the high prices recorded in many instances do not appear surprising. A curious collection of scattered notices of this kind is given in the first volume of Warton's *History of English Poetry*. A catalogue of the books in the Sorbonne in 1292, consisting of upwards of 1000 volumes, is mentioned by Chevillier[1] as having been valued at 3812 livres, equivalent, according to an English writer, to as many pounds sterling of the present day. In 1425, when the English became masters of Paris, the duke of Bedford, regent of France, sent the whole of the royal library into England; and the collection, which amounted to only 853 volumes, was valued at 2223 livres.

The characteristics of early printed books are noticed under the head of BIBLIOGRAPHY (*q. v.*) The folio and quarto sizes, originally adopted from the largeness of the types in the infancy of printing, are now generally restricted to works of bulk, as dictionaries and other books of reference. The size of a printed book is named from the dimensions of the paper and the number of leaves into which it is folded. The ordinary sizes for a long time were royal, demy, and crown; and the demy 8vo is now the commonest size in use. Post and foolscap are frequently but inaccurately described in catalogues as duodecimo. "Paper-moulds," says Mr W. Blades,[2] a competent authority on this subject, "have fixed conventional sizes; but since the introduction of machines for making paper, and the consequent disuse of moulds, makers work more by a given number of inches than by names of sizes. Consequently, the correct description of book sizes has become impossible, and the trade describe the new by the names of the old size they most resemble. To determine the real size of a bound book," he adds, "find the signature (a letter or figure at the bottom of the page), and count the *leaves* (not pages) to the next. A further test is the binder's thread in the middle of the sheet; the number of leaves from each thread to the next will give the same result. But these rules do not apply to old black-letter books and those of the 15th and 16th centuries, in which the most satisfactory test is the water-mark. The rule is:—a folio volume will have all the water-marks in the middle of the page; a quarto has the water-mark folded in half in the back of the book, still midway between the top and bottom; in an octavo it is at the back, but at the top, and often Printed books.

[1] *Origines de l'imprimerie de Paris*, p. 370.
[2] *Notes and Queries*, 3d series, ix. 83.

considerably cropped by the binder's plough; and a 12mo and 16mo have the water-mark on the fore-edge." For further information regarding MS. books see PALÆOGRAPHY, and for printed books BIBLIOGRAPHY. (E. F. T.)

Bookselling.

The trade in books is of a very ancient date. The early poets and orators recited their effusions in public to induce their hearers to possess written copies of their poems or orations. Frequently they were taken down *viva voce*, and transcripts sold to such as were wealthy enough to purchase. In the book of Jeremiah the prophet is represented as dictating to Baruch the scribe, who, when questioned, described the mode in which his book was written. These scribes were, in fact, the earliest booksellers, and supplied copies as they were demanded. Aristotle, we are told, possessed a somewhat extensive library; and Plato is recorded to have paid the large sum of one hundred minæ for three small treatises of Philolaus the Pythagorean. When the Alexandrian library was founded about 300 B.C., various expedients were resorted to for the purpose of procuring books, and this appears to have stimulated the energies of the Athenian booksellers, who were termed βιβλίων κάπηλοι. In Rome, towards the end of the Republic, it became the fashion to have a library as part of the household furniture; and the booksellers, *librarii* (Cic., *De Leg.*, iii. 20) or *bibliopolæ* (Martial, iv. 71, xiii. 3), carried on a flourishing trade. Their shops (*taberna librarii*, Cicero, *Phil.*, ii. 9) were chiefly in the Argiletum, and in the Vicus Sandalarius. On the door, or on the side posts, was a list of the books on sale; and Martial (i. 118), who mentions this also, says that a copy of his First Book of Epigrams might be purchased for five denarii. In the time of Augustus the great booksellers were the Sosii. According to Justinian (ii. 1, 33), a law was passed securing to the scribes the property in the materials used; and in this may, perhaps, be traced the first germ of the modern law of copyright.

The spread of Christianity naturally created a great demand for copies of the Gospels and other sacred books, and later on for Missals and other devotional volumes for church and private use. Benedict Biscop, the founder of the abbey at Wearmouth in England, brought home with him from France (671) a whole cargo of books, part of which he had "bought," but from whom is not mentioned. Passing by the intermediate ages we find that, previous to the Reformation, the text writers or stationers (*stacyoneres*), who sold copies of the books then in use,—the A B C, the Paternoster, Creed, Ave Maria, and other MS. copies of prayers, in the neighbourhood of St Paul's, London,—were, in 1403, formed into a guild. Some of these "stacyoneres" had stalls or stations built against the very walls of the cathedral itself, in the same manner as they are still to be found in some of the older Continental cities. In Mr Anstey's *Munimenta Academica*, published under the direction of the Master of the Rolls, we catch a glimpse of the "sworn" university bookseller or stationer, John More of Oxford, who apparently first supplied pupils with their books, and then acted the part of a pawnbroker. Mr Anstey says (p. 77), "The fact is that they (the students) mostly could not afford to buy books, and had they been able, would not have found the advantage so considerable as might be supposed, the instruction given being almost wholly oral. The chief source of supplying books was by purchase from the university sworn stationers, who had to a great extent a monopoly Of such books there were plainly very large numbers constantly changing hands." Besides the sworn stationers there were many booksellers in Oxford who were not sworn; for one of the statutes, passed in the year 1373, expressly recites that, in consequence of their presence, "books of great value are sold and carried away from Oxford, the owners of them are cheated, and the sworn stationers are deprived of their lawful business." It was therefore enacted that no bookseller except two sworn stationers, or their deputies, should sell any book being either his own property or that of another, exceeding half a mark in value, under pain of imprisonment, or, if the offence was repeated, of abjuring his trade within the university.

"The trade in bookselling seems," says Hallam, "to have been established at Paris and Bologna in the 12th century; the lawyers and universities called it into life. It is very improbable that it existed in what we properly call the Dark Ages. Peter of Blois mentions a book which he had bought of a public dealer (*a quodam publico mangone librorum*); but we do not find many distinct accounts of them till the next age. These dealers were denominated *stationarii*, perhaps from the open stalls at which they carried on their business, though *statio* is a general word for a shop in low Latin. They appear, by the old statutes of the University of Paris, and by those of Bologna, to have sold books upon commission, and are sometimes, though not uniformly, distinguished from the *librarii*, a word which, having originally been confined to the copyists of books, was afterwards applied to those who traded in them. They sold parchment and other materials of writing, which have retained the name of stationery, and they naturally exercised the kindred occupations of binding and decorating. They probably employed transcribers; we find at least that there was a profession of copyists in the universities and in large cities."

The modern system of bookselling dates from soon after the introduction of printing. The earliest printers were also editors and booksellers; but being unable to sell every copy of the works they printed, they had agents at most of the seats of learning. Antony Koburger, who introduced the art of printing into Nuremberg in 1470, although a printer, was more of a bookseller; for, besides his own sixteen shops, we are informed by his biographers that he had agents for the sale of his books in every city of Christendom. Wynkin de Worde, who succeeded to Caxton's press in Westminster, had a shop in Fleet Street.

The religious dissensions of the Continent, and the Reformation in England under Henry VIII. and Edward VI., created a great demand for books; but in England neither Tudor nor Stuart could tolerate a free press, and various efforts were made to curb it. The first patent for the office of king's printer was granted to Thomas Berthelet by Henry VIII. in 1529, but only such books as were first licensed were to be printed. At that time even the purchase or possession of an unlicensed book was a punishable offence. In 1556 (3 and 4 Philip and Mary) the London Company of Stationers was incorporated, and very extensive powers were granted in order that obnoxious books might be repressed. In the following reigns the Star Chamber exercised a pretty effectual censorship; but in spite of all precaution, such was the demand for books of a polemical nature, that many were printed abroad and surreptitiously introduced into England. Queen Elizabeth interfered but little with books except when they emanated from Roman Catholics, or touched upon her royal prerogatives; and towards the end of her reign, and during that of her pedantic successor, James, bookselling flourished. Archbishop Laud, who was no friend to booksellers, introduced many arbitrary restrictions; but they were all, or nearly all, removed during the time of the Commonwealth. So much had bookselling increased during the Protectorate that, in 1658, was published *A Catalogue of the most Vendible Books in England, digested under the heads of Divinity, History, Physic, &c., with School Books, Hebrew, Greek, and Latin, and an Introduction, for the use of*

Schools, by W. London. A bad time immediately followed. The Restoration also restored the office of Licenser of the Press, which continued till 1694.

In the first Copyright Act (8 Anne, c. 19), which specially relates to booksellers, it is enacted that, if any person shall think the published price of a book unreasonably high, he may thereupon make complaint to the archbishop of Canterbury, and to certain other persons named, who shall thereupon examine into his complaint, and if well founded reduce the price; and any bookseller charging more than the price so fixed shall be fined £5 for every copy sold. Apparently this enactment remained a dead letter.

The modern bookselling trade divides itself into the several branches of publishing and *wholesale bookselling*, and *the retail*, *the old or second-hand*, and the periodical trades. Publishing is confined to a few of the larger cities, London naturally taking the lead, followed by Edinburgh, Glasgow, Oxford, Manchester, Liverpool, Cambridge, Dublin, and a few other places; while purely wholesale dealers are to be found in the large towns only. In Great Britain, and especially in Scotland, booksellers are located in every small town; but in Ireland there are very few, except in the chief cities. Formerly the retail booksellers were expected to demand the full retail price of a book, and make no greater reduction than discount for ready money; but this restriction has been discontinued as contrary to the spirit of free trade. The trade in old or (they are sometimes called) second-hand books is in a sense a higher class of business, requiring a knowledge of bibliography, while the transactions are with individual books rather than with numbers of copies. Occasionally dealers in this class of books replenish their stocks by purchasing remainders of books, which, having ceased from one cause or another to sell with the publisher, they offer to the public as bargains. The periodical trade is entirely the growth of the present century, and was in its infancy when the *Penny Magazine*, *Chambers's Journal*, and similar publications first appeared. The growth of this important part of the business has been greatly promoted by the abolition of the newspaper stamp and of the duty upon paper, the introduction of attractive illustrations, and the facilities offered for purchasing books by instalments.

The history of bookselling in the New World has yet to be written. The Spanish settlements in America drew away from the old country much of its enterprise and best talent, and the presses of Mexico and other cities teemed with publications mostly of a religious character, but many others, especially linguistic and historical, were also published. Bookselling in the United States was of a somewhat later growth, although printing was introduced into New York as early as 1673, Boston in 1674, and Philadelphia in 1683. Franklin had served to make the trade illustrious, yet few persons were engaged in it at the commencement of the present century. Books chiefly for scholars and libraries were imported from Europe; but after the second war printing-presses multiplied rapidly, and with the spread of newspapers and education there also arose a demand for books, and publishers set to work to secure the advantages offered by the wide field of English literature, the whole of which they had the liberty of reaping free of all cost beyond that of production. The works of Scott, Byron, Moore, Southey, Wordsworth, and indeed of every author of note, were reprinted without the smallest payment to author or proprietor. Half the names of the authors in the so called "American" catalogue of books printed between 1820 and 1852 are British. By this means the works of the best authors have been brought to the doors of all classes in the cheapest variety of forms. In consequence of the war with the Southern States, the high price of labour, and the restrictive duties laid on in order to protect native industry, coupled with the frequent intercourse between the two countries, a great change has taken place during the last few years. Books printed and bound in Britain are greatly appreciated, and American publishers, in the absence of an international copyright, make liberal offers for early sheets of new publications. Boston, New York, and Philadelphia still retain their old supremacy as bookselling centres.

In Australia the sale of books is not large at present; there are, however, indications of a great increase. The booksellers there as in Canada, although supposed to be bound by the copyright law restricting the sale of any but genuine editions, avail themselves of American and other reprints, in which the authors have little or no interest.

In the course of the 16th and 17th centuries the Low Countries for a time became the chief centre of the bookselling world, and many of the finest folios and quartos in our libraries bear the names of Jansen, Blauw, or Plantin, with the imprint of Amsterdam, Utrecht, Leyden, or Antwerp, while the Elzevirs besides other works produced their charming little pocket classics. The southern towns of Douai and St Omer at the same time furnished polemical works in English.

Germany, the birthplace of the art of printing, is still the first bookselling country in the world. There, distributed over 786 towns, are 3473 publishers and booksellers, Leipsic being the centre to which they all look, all of any consequence having an agency there, where their books are collected, and their own publications distributed. In Leipsic there are 105 commission-agents for 4202 booksellers, of whom 1143 carry on business in Austria, France, Russia, Holland, America, and England. The book exchange has 115 members who transact business there. The other centres of the German book trade are Stuttgart, with 16 agents for 542 booksellers; Vienna, with 31 agents for 475; Berlin, with 29 agents for 305; and Prague, with 18 agents for 98. The great book fair at Leipsic is held every year immediately after Easter, and is attended by booksellers from every part of the world.

In France the press is still shackled, and every book and pamphlet must be registered before publication; but notwithstanding this booksellers flourish, especially in all the large towns, and some of the finest illustrated works of the day are issued from the French press. In Italy booksellers are few, and in Spain they can hardly be said to have any existence at all.

From the *English Catalogue of Books for* 1874 it appears that there were about 4500 books published in Great Britain and Ireland during that year. This number includes new editions of works previously issued, as well as the principal books published in the United States.

The values of books exported and imported during 1874 are given in the official returns as follows:—

Exports.

To United States	£274,373
„ Australia	267,658
„ British India and Ceylon	83,259
„ British N. America	69,127
„ France	41,622
„ South Africa	35,986
„ Holland	21,912
„ Germany	19,894
„ Belgium	16,953
„ British West Indies and Guiana	14,469
„ Other countries	59,539
Total	£904,792

Imports.

From France	£57,680
„ Germany	36,494
„ Holland	31,837
„ United States	17,807
„ Belgium	16,254
„ Spain	4,177
„ Italy	1,328
„ Other countries	13,359
Total	£178,956

Much interesting information on the book trade will be found in Charles Knight's *Biography of William Caxton*,

and in the same author's *Shadows of the Old Booksellers*, 1865. See also *History of Booksellers*, by Henry Curwen, 1873, and *Bilder-Hefte zur Geschichte des Bücherhandels*, by Heinrich Lempertz, Cologne, 1854.

BOOKBINDING is the art of fastening together the sheets of paper composing a book, and enclosing them in cases of pasteboard covered with leather, cloth, or other materials,—the object being the preservation of the book, and its protection from injury while in use.

At the time when books were rarities, being either manuscripts produced by patient secluded labour or the productions of the printing-press during the infancy of typography, they were naturally very highly prized; and as much labour and expense were bestowed upon the protection and embellishment of a cherished folio as would suffice at the present day for the building of a house. The wooden cover of a book, with its metal hinges, bosses, guards, and clasps, seems, in all but dimensions, fit for a church door; but the great improvement in all the mechanical arts, together with the extension of education to all classes, and the consequent diffusion of knowledge, has led to the multiplication of books, and the gradual but radical changes witnessed during the present century in the art of bookbinding.

For a period of one thousand years—from the end of the 5th to the 15th century—books were excessively rare and costly, and comparatively few bindings illustrative of the art during the Dark Ages have been preserved to the present day. From being the task of slaves during the Roman empire, the transcribing of books came to be the duty of monks, who copied and bound the works which were among the chief treasures of religious establishments. Numerous documents exist indicating the attention which was given by all grades of the priestly order to the binding and preservation of their literary treasures. The general aspect of monastic bindings was thick, heavy, and solid, and according to modern ideas somewhat clumsy. Books for common use were enclosed in boards of hard wood covered with leather, with the binding protected by metallic bosses, corner plates, and clasps. The literary treasures, on the other hand, of kings and ecclesiastical dignitaries, and the sacred volumes of churches and monasteries, were encased in ivory sides, with appropriate subjects artistically carved on them, in silver and sometimes even gold *plaques*, or in the enamels of Limoges, &c.; and these bindings were frequently enriched besides with gems and jewels. Often these precious volumes were, in keeping with ancient customs, further preserved in boxes or cases no less rich and costly than the bindings they were meant to preserve. As the period of the Renaissance approached, silk and velvet came into use for ornamental bindings.

The most ancient binding in the British Museum is the St Cuthbert gospels and manuscript, written about the beginning of the 8th century, bound in velvet intermixed with silver, with a broad silver border, enriched with inlaid gems. One of the most ancient and remarkable of bindings, a *Lectionarium*, which was formerly in the collection of M. Libri, that eminent bibliophile thus describes in his *Monuments inédits*: "Manuscript upon vellum of the 11th or 12th century in an ornamented cover (forming a diptych), both sides being gilt and silvered metal, with ivory carvings, figures in *alto rilievo*, and enamels *en taille d'épargne*. The borders contain thirty-two large ivory medallions (sixteen on each side), representing the old prophets and saints, with their symbols, and having inscriptions in ancient uncial letters, the whole surrounded with a foliage of ivory work in the Greek style, and with baguettes carved in compartments. The ivory medallions are very early, probably as old as the 6th century, whilst the enamels and metal ornamentation are specimens of the handiwork of a rather later period. . . . This *Lectionarium* has evidently been inserted in the present cover at a later period, the original one having most probably been damaged or destroyed by use." Referring to this work, M. Libri, in the introduction to the volume above quoted, says: "Whether the enamels contained in this binding are Byzantine and contemporary with the ivory sculptures, or were introduced later (as we have shown was frequently the case) into an older covering, the medallions and other workmanship in ivory, adorning the sides of this coating, appear, from the character of the heads, from the inscriptions, and from the workmanship itself, to date back to the earliest period of the Byzantine school."

With the invention of printing, and the consequent multiplication of books in a portable shape, came the modern style of bookbinding. The old massive boards, with their bosses, corner plates, and heavy clasps disappeared, and thin sides covered with leather, parchment, and vellum came into use. Bindings in which enamels, precious metals, or gems were employed almost entirely disappeared, and were followed by bindings in richly-coloured leather or vellum, with elaborate designs, blind-tooled or worked in gold and colour, and gilt gauffré edges. By the wealthy and powerful families of Italy this style of binding and ornamentation was first encouraged towards the end of the 15th century, and skilful artists were employed to design appropriate decorations to be worked out by the bookbinders. Among the most famous early patrons of the bibliopegic art in Italy were Michael and Thomas Maioli, the books of the latter being the models on which were fashioned the bindings of later collectors and of other countries. More rare and artistically valuable still are the works of another Italian collector of the 16th century, Demetrio Canevari, commonly called Mecenate, physician to Pope Urban. They are distinguished by a medallion executed in gold, silver, and colour, with the device of a charioteer driving towards Pegasus on an elevation, and the motto, ΟΡΘΩΣ. ΚΑΙ. ΜΗ. ΛΟΞΙΩΣ. These elegantly gilt bindings have, in the opinion of M. Libri, never been surpassed.

Artistic bindings of Italy and Italian binders were brought to France by Charles VIII. and Louis XII.; but it was not till the time of Francis I.—himself a lover of books and bindings—that Grolier, his military treasurer and the governor of Milan, brought the French school of binding suddenly to the front, and placed it, where it long remained, at the head of the art in Europe. The bindings executed for Grolier usually contain on their obverse the inscription, IO. GROLIERII ET AMICORUM, and on the reverse his usual motto was PORTIO MEA DOMINE SIT IN TERRA VIVENTIUM. Of Grolier's bindings the learned De Thou, a later and little less famous French bibliophile, remarked "that his books partook of the elegance and polish of their owner." The Grolier style is yet recognized as the most chaste, elegant, and appropriate method of book ornamentation, and it immediately attained an enormous reputation in France. "The very tools used by his binders," remarks M. Libri, "were employed for contemporary collectors, and his admirable patterns have been imitated and copied by other French bibliophiles. The gradual change in those patterns is very perceptible. At first they were formed by a simple and chaste combination of various links only; but afterwards Grolier successively introduced into the designs more rich ornaments, such as small flowers, wreaths, &c." Some of his later covers were resplendent with gold and coloured ornament, most elaborately tooled.

After the period of Grolier the taste for magnificent bindings in France grew into a passion, and the sumptuous bindings in which the famous Diana of Poitiers indulged

are almost without parallel. The designs for many of her bindings are said to have been prepared by order of her royal lover Henry II., under the superintendence of the celebrated artist Le Petit Bernard. Her books are marked with her favourite symbols, the lunar crescent and the bow, and the monogram D ɑ, sometimes (probably in the case of love-gifts) with the H of Henry interlaced, and surmounted by the crown. It would be a useless and almost endless task to name the patrons of artistic bindings up to near the period of the revolutionary outbreak, during which long time French binders stood at the head of their craft. Such outstanding names among many bibliophiles as those of the historian De Thou (Jacobus Augustus Thuanus) and Colbert, the minister of Louis XIV., cannot be passed over. Such was Colbert's care for artistic bookbinding that, in a treaty with Marocco, he inserted a stipulation for a certain number of skins annually to be used for bindings in the *Bibliothèque Royale*. Much less is known concerning the bookbinders themselves than of their patrons and the works they executed; but prominent among the bibliopegic artists of all times stand the chief French *relieurs* of the 17th and 18th centuries—Le Gascon, Abbé Dusseuil, Padeloup, and Derome. Bindings by these artists are among the esteemed prizes of modern collectors.

Although during the 16th and 17th centuries bindings were produced in England which suffer no disgrace by comparison with contemporary masterpieces of French, Italian, and German bibliopegy, it was not till well into the 18th century that England took the leading place in the workmanlike forwarding and artistic finishing of books. Silk and velvet long remained the favourite coverings for the more costly bound books in the royal library, and down to the time of James I. we find very elaborately worked bindings in these substances. But, at the same time, there are not wanting magnificent examples of work in calf, morocco, and vellum, with blind and gold toolings, and gilt gauffré edges. The bindings of John Reynes, bookbinder to Henry VIII., had embossed on them the curious heraldic conceit of a shield, supported by a pair of unicorns, charged with the emblems of the passion, and along with his monogram the inscription *Redemptoris mundi arma*. Before James VI. of Scotland came as James I to the English throne, he was, as became his literary character, a collector of books and a lover of bindings. John Gibson of Edinburgh held, under James, the office of royal binder, with an annual salary of £20 Scots. A detailed list of bindings, with the prices charged by Gibson, is printed by the Bannatyne Club in *The Library of Mary Queen of Scots and James VI.* Mr J. T. Gibson-Craig of Edinburgh has in his excellent collection an original Scotch binding from the library of Queen Mary, the *Cronique de Savoye*, a small folio in brown calf, richly tooled in silver, with the Scottish arms, and the initial M. The same collector also possesses a Scotch binding in brown calf, with blind and gold panelling, gilt and gauffré edges, with the name and arms of the Earl of Bothwell, the third husband of Queen Mary. De Quincey, in a paper on "Secret Societies," ranks a Bible bound by Mr Farrer in 1635 above the *chefs d'œuvre* of British and Continental artists.

The acknowledged supremacy attained by English bookbinding in the latter half of last century is due in large measure to the work of Roger Payne, a man gifted with extraordinary skill, dexterity, and taste, but unfortunately also of the most erratic and dissolute habits. Payne's work was, as he himself expressed it, "very carefully and honestly done;" his tooling especially was very beautiful, and his ornaments, many of which he fashioned with his own hands, were at once highly appropriate and artistic. In his bills he was in the habit of taking his patrons into his confidence in an unusual manner, and one of these may be worth copying.

"*Aeschylus Glasguæ MDCCXCV Flaxman illustravit.* Bound in the very best manner, sew'd with strong Silk, every Sheet round every Band, not false bands: the Back lined with Russia Leather, Cut Exceeding large; Finished in the most magnificent manner. Embordered with ERMINE expressive of The High Rank of the Noble Patroness of The Designs, The other Parts Finished in the most Elegant Taste with small Tool Gold Borders Studded with Gold; and small Tool Panes of the most exact Work. Measured with the Compasses. It takes a great deal of Time making out the different measurements, preparing the Tools, and making out new Patterns. The Back Finished in Compartments with parts of Gold studded work and open Work to relieve the Rich close studded work. All the Tools except studded points are obliged to be worked off plain first, and afterwards the Gold laid on and Worked off again. And this Gold Work requires double Gold being on Rough Grained Morocco. The impressions of the Tools must be fitted and cover'd at the bottom with Gold to prevent flaws and cracks."

Payne, in poverty and distress, came prematurely to a drunkard's grave in 1797. His style of binding has still many admirers, and the Roger Payne style is one of the established methods of finishing in bookbinders' establishments at the present day. After Payne, Charles Lewis was the next famous English binder flourishing in London in the early part of the present century, and his bindings come down to and connect with the work of bibliopegistic artists who still exercise their calling.

The operations of bookbinding are now carried on upon a scale which could not have been dreamt of even at the beginning of the present century, and the millions of volumes which annually issue from the press could not possibly be put into the hands of the reading public in the form and at the price at which they are sold without the aid of machinery. In Great Britain nearly all books are first issued in cloth cases, and while the greatest variety of grain and colouring has been reached in the preparation of the cloth for such cases, their gilding, embossing, and lettering, all accomplished by machinery, leave almost no improvement to be desired, and the most handsome and fairly durable bindings can thus be supplied at an incredibly small cost. At the same time, it is practicable to prepare, emboss, and gild cheap leather covers by the same processes and machinery adopted for cloth cases, and the bindings of cheap family and pocket Bibles are thus produced. But although the old solid and substantial handiwork of the craft is thus fairly eclipsed, there is still employment—and more employment than ever—for binders in leather, who chiefly rely on manual dexterity for the forwarding of their work, and individual taste and skill for its artistic finishing.

Modern bookbinding thus divides itself into two principal branches—1st, Leather work, and all kinds in which manual labour and skill are chiefly employed; and 2d, Cloth-casing, or such work as is largely executed by the aid of machinery.

It may be convenient first to notice the various operations through which a book passes in ordinary or leather binding. These operations are grouped under two main divisions—"forwarding" and "finishing." Under the first is comprehended everything necessary to the preservation of a book; the second concerns merely the embellishment.

Forwarding.—In the first place, the sheets of a book are *folded* in such a manner that the pages follow each other in consecutive order. In this operation the binder is guided by the "signatures," which indicate the part of a sheet to be superimposed upon another. This labour is performed by women and girls, who acquire incredible dexterity by continued practice. The sheets, after being folded, are loose and bulky. The next operation has for its object the bringing them into a more compact form, which was formerly accomplished by beating them with a broad-faced hammer upon a smooth flat stone. The condensing or compacting is now generally accomplished by passing the sheets between the cylinders of a rolling-machine. A quantity of sheets, called a "section," is gathered and arranged between two pieces of tin plate and passed through

between the powerful cast-iron rollers of the machine. After rolling, the sections composing a volume, supposing it to have been necessary to press it in more than one division, are brought together and carefully collated. The whole of the sheets to compose the volume being found in their proper place and order, they are taken in sections to the standing-press, in which a number of them are piled up between boards. The form of standing-press generally used is what is termed the Atholl or Isle of Man press, on account of the three arms, or rather legs, by which the compound screw of the press is worked.

The volumes are then adjusted and clamped up in the laying or cutting-press for the operation of *sawing the back*. Two or three grooves are, in this operation, sawn straight across the back of the volume, according to the number of bands on which the book is to be sewed. In these grooves the bands are lodged, so that when the sewing of the book is complete, the bands are "flush" with the rest of the back, instead of projecting out as they did in old times. A slight cut is made near each end for holding the "kettle stitch," or stitch by which the sewer fastens her thread each time she passes up and down. The *sewing* is done at an apparatus called the sewing-press or frame, upon which the number of cords to be employed are fastened at proper distances, in accordance with the saw-marks in the back of the volume. The method of sewing varies according as the sewer is working one or two "sheets on;" and the number of bands employed may be from two to six, according to the size of sheet, weight of the book, &c. When taken out of the sewing-frame the fly-leaves are pasted on, and the volume being neatly squared, the back is covered with a coating of thin glue; it is then laid on a board and allowed gradually to dry. When the glue is quite dry the back is *rounded* by beating with a hammer, and subsequently the volume is placed between two feather-edged boards, above which the back slightly projects. These are then placed together in a lying-press, for the *backing* process, that is, the back of the book is well beaten until it projects a little over each side of the bevelled board, so as to form a groove or place for the millboard covers to lie in. The book is now ready for the *boarding*. The boards were formerly, as the name indicates, really of wood, but now of millboard of various thicknesses, according to the size of the book. They are cut a little larger than the book itself, and are attached by the ends of the bands, left for that purpose, being passed through holes in the sides of the boards. The ends of the slips or bands are then frayed out, pasted down, and hammered flat and smooth. The volume is next placed between pressing boards, and put with others into the standing-press, where it is submitted to a powerful pressure for several hours. Thereafter it is again fastened into a lying-press for cutting or *ploughing* the edges with a knife-edged instrument called the plough. The object of the binder in this operation is to make every page of uniform size, presenting a smooth and equal "head," "tail," and "fore-edge." The binder is careful to leave as broad a margin as practicable; but the size of the smallest sheet is the real gauge of the whole book. The head is first cut, next the tail, and before the face is cut it is necessary to have the back flattened by passing "trindles" through between the cords and the boards. After the face has been ploughed the back springs back into its rounded form, and thus the face presents the appearance of having been cut in the round.

The book is now ready to have its edges either *sprinkled*, *coloured*, *marbled*, or *gilt*. *Sprinkling* is accomplished by merely mixing the colour or colours with paste or size, and throwing the mixture from a brush violently on the edges. The uniform *colouring* of the edges is done by screwing the volume up in the lying-press and applying the colour with a sponge. *Marbling* is usually carried on as a separate trade, and requires considerable adroitness. The colours to be used are thrown into a square shallow trough containing prepared gum water, and as they float on the top they are dexterously mixed and combed through each other so as to produce the kind of marble pattern desired. In this the edges to be marbled are dipped, and when they are withdrawn it is found that the marbled colours have adhered to them. In the *gilding* the fore-edge or face is first operated on; and to level it the back must again be flattened, as in ploughing. The book is then firmly fixed in the lying-press, and the edges are scraped and smoothed with a steel scraper. The edges are next coloured, the gold size, consisting of white of egg mixed with water, called glaire, is laid on with a camel's-hair brush, and immediately covered with gold leaf. When dry, it is burnished by rubbing with an agate burnisher, and the head and tail are put through the same processes. Gilt edges in early bound books were usually *gauffré*, *i.e.*, had designs impressed on them; but scarcely any such work is now done.

The head-bands, which are next attached to the back head and tail, are ornamental appendages, which partly conceal the folded-in edges of the leather, and give a finished aspect to the book. They consist of strips of vellum or parchment worked over with coloured silk or cotton, and are partly glued to the backs and partly fastened by threads passing through the kettle stitches. The back is then lined with strong paper glued on it, two or three thicknesses being used according to the weight of the book. Nearly all books are now bound with open or elastic backs, that is, with the leather of the cover not attached to the back of the sheets. The elastic back is composed of a strip of thin cardboard as long as the volume and a little broader than the back, so that it covers the whole back, and is glued in the joint at the edge of the millboards. Across this elastic back false bands are glued to imitate the projections produced by the cords of ancient bindings; and when these are dry, the book is ready for covering.

The materials used for *covering* are very various; but for the greater part of modern books calf-skin dyed of various colours is employed; while kid-skin, and its imitation in sheep-skin or roan, and sheep-skin acknowledged as such, in which school-books and many law-books are bound, are also used in great quantities. The piece of leather, cut to a proper size, is moistened with water, next covered on the inner side with paste or glue, and then applied evenly to the millboard sides. The superfluous edge of the leather, first pared to reduce its thickness, is turned over on the inside, and concealed from view by the end papers attached to the sheets forming the book, which are subsequently pasted down upon the millboards. As a last operation in forwarding, but one now frequently omitted, the book is "corded," that is, firmly tied between two boards until it is dry, so as to insure perfect smoothness in the cover. A book is *half-bound* when only the back and corners are protected with leather, the rest of the boards being covered with prepared paper or cloth.

Finishing.—Finishing processes are so varied and numerous, according to the material under treatment and the effect to be produced, that a lengthy treatise would be required to detail the operations. It will suffice here to notice the operations in finishing an ordinary white-calf binding. The whole of the leather is first washed over with a thin paste of the consistency of cream and allowed to dry. The colouring is then done by brushing over it a solution of "salts of tartar" (tartrate of potash), which produces the brown tint of ordinary bindings. If the sides are to be further ornamented, as, for example, by forming "tree-calf," they are washed over with glaire (white of egg). Each board when dry is separately bent convex, and water is sprinkled on till it runs downwards from the central ridge in a great number of separate branching runlets. As the water is so running, a solution of copperas is sprinkled on and carried along and out by every tricklet, and thus the dark-coloured branched markings are produced. The appearance of "French calf" is produced by dabbing copperas from a sponge on the brown covers. The back is next *pieced for title*, by pasting a piece of coloured morocco into the space between the first and second bands. The points at which lines either blind or in gold are to cross the back are then marked, the whole back is washed with thin paste, and two coatings of glaire are applied to it. When dry the gold leaf is laid on, the lines and ornaments are tooled, and the title lettered with tools and letters which have been heated at a gas stove. The superfluous gold is cleaned off, and after polishing the whole with a hot iron tool the back is finished. The same processes are followed with the sides and the "squares" when any ornamentation is tooled upon them. In the case of finishing of a high class, in morocco, &c., the ornaments are first tooled blind, glaire is pencilled into the lines, and allowed to dry, and gold leaf is then laid on and tooled in. A book is said to be bound *extra* when well forwarded, lined with superior paper, and gilt round the sides and inside the squares.

Casing.—Previous to the year 1825, new books were generally issued in *boards*, that is, in millboards covered with drab paper, upon which the title, printed on a white label, was pasted. Although this was greatly superior to the Continental mode of covering new books with thin paper, something more elegant and durable was needed, and Mr Archibald Leighton of London endeavoured to meet this want by introducing coloured cloth (glazed calico). One of the first books of importance bound in this material was the edition of Lord Byron's works in seventeen volumes. The covering of books in cloth cases can be done profitably only in a factory where there is much division of labour and many labour-saving machines. In cloth binding the preparation and ornamentation of the cases are throughout distinct from the preparation of the sheets, and it is only in the very last stage that the volume and its case are brought together. The first process in the preparation of the cloth cases is cutting the millboard. This is now effected by a rotary cutting-machine or "ripper," an invention introduced from America, whence indeed comes most of the machinery used in this species of binding. The machine consists essentially of a pair of strong spindles placed above each other, on which are mounted circular scissor-edged discs, which cut in pairs like the blades of a pair of scissors. The cutting discs can be arranged on the spindles to cut any desired size of board, and the gauge-frame on the feeding table pushes the pieces of millboard into the machine by a motion communicated by a cam-wheel. Such a machine will cut 50,000 pairs of boards in the working hours of a week. When the boards are to be bevelled this is done in a kind of planing-machine. The cloth for the covers being cut to the required size and covered with glue, a pair of boards are laid on with the help of a brass gauge,

which keeps them parallel, and regulates the width of the space to be left for the back. A strip of paper is pasted into the back, the edges of the cloth are laid in, and the boards are passed between a pair of india-rubber rollers, by the pressure of which any air-spaces between the cloth and the millboards are squeezed out. They are then hung up to dry previous to receiving title and ornamentation. The ornamentation on book cases consists of embossing or blind tooling, black or colour printing, and gilding; and the machines in which the work is done are the same in principle. They are powerful presses, worked either by long lever handles or by power with heavy fly-wheels. Blind patterns, or gilded work and titling, are done at one operation, the dies containing the pattern being heated either with steam or gas. In the case of ornaments to be printed in ink, the pattern is first blocked in the blind with a heated die, and subsequently ink-printed in the same press with the die cold.

The gathering, collating, and stitching of the sheets differ in no way from the same processes already described for leather work. Machinery has been adapted for folding, but, for the working of folding-machines, guide points require to be printed on the sheets, as books must be folded by the type and not by the edge of the sheet. A machine of American origin, besides folding 8vo sheets, will cut, fold, and insert the half sheet of a 12mo. This machine, attended by a single girl, is sufficient to fold from 1200 to 1500 sheets in an hour. The folded sheets are sometimes condensed in another American machine called "The Smasher," which is similar in its action to the embossing press. After stitching, books which are to be cased up with uncut edges have their face and tail cut square by means of a trimming-machine. The principle of this machine consists in a revolving circular knife driven with a treadle or handle; a table (containing the gauge, press bar, and rest), upon which the books are placed, glides across the axis of the knife, and the parts requiring cutting off, coming in contact with the revolving knife, are cut away. When the edges are to be gilt they are cut in some of the numerous forms of guillotine cutting-machines. The commonest form of guillotine is a heavy knife fixed in a strong framework, and having a diagonal motion in its descent by which it cuts with a kind of shearing action. In another machine the knife acts with a punching motion, and cuts the three edges in one descent; and there is in use a most ingenious American machine, with a revolving table, in which each edge of the book is in succession drawn in a slanting direction up against a fixed cutter. The edges are gilt as in ordinary binding, but instead of each volume being operated on singly, a number are placed evenly in a lying press and gilt simultaneously.

After trimming or gilding, as the case may be, the backs are glued up, and when dry they are rounded, generally with the hammer. Several machines have been devised to perform this operation, and one patented in 1865 by Messrs Cope and Bradbrook has come into extensive use. In this machine the book is clamped up between a pair of horizontal cheeks on a table which moves backwards and forwards under a heavy roller adjusted in a frame over the table. The pressure of the roller against the back gives the required "round," which can be varied by raising or lowering the pitch of the roller. From the rounding process the volume goes to the backing-machine, by which the joint or groove along the back in which the boards lie is formed. The backing-machine is worked by the hand, and its action is somewhat similar to that of the rounding-machine. The book is seized between a pair of jaws, which only leave about a quarter of an inch projecting above them. The workman brings down a roller on this projecting part of the volume, and its pressure forces the free portion of end sheets over the sides of the jaws, thus forming the joint to receive the boards. With the backing the part of the work done by machinery ends. The backs are next coated with glue, pieces of calico for pasting down are laid on, and the entire back is covered with paper. When dry, the volume is fitted into its cases and "pasted up," and the operations are finished by piling the cased books in a hydraulic press between boards, so as to leave only the backs projecting.

A kind of binding in which the process of sewing is dispensed with, and the backs coated with a rapidly-drying solution of india-rubber, was patented by Mr William Hancock in 1836, and is still used to some extent. The sheets in this binding must either be cut into single leaves or folded as folios, as they all require to be agglutinated by repeated coatings of the india-rubber solution. The india-rubber backing is convenient for volumes of plates, music books, and any volumes made up of large separate sheets.

Although cloth casing is found sufficient for the greater proportion of the literature which now circulates so extensively, books of reference and works in public libraries require the more secure and workmanlike binding accomplished by hand. At the same time, while ornaments stamped from dies may be very pretty and effective, they have no claim to rank as works of art, and for the collections of bibliophiles the hand-tooling of bibliopegic artists is in as great demand and as handsomely remunerated as was the art of the most accomplished binders of the 16th century. (J. PA.)

BOOK-KEEPING.—The object of book-keeping is to exhibit a distinct and correct state of one's affairs, and to enable companies, firms, and individuals in trade, or otherwise occupied, to ascertain at any time the nature and extent of their business, the amount of their profits or available income, or, as the case may be, the extent of their losses.

To those engaged in trade or commercial pursuits book-keeping is absolutely necessary, as by it all transactions should be regulated, and their results exhibited. The more simple the system the better; but care must be taken that the plan adopted is sufficiently comprehensive and explanatory, to satisfy not only the person keeping the books, but those who may have occasion to refer to them; for, however satisfactory it may be to a trader to follow a system which is intelligible to himself alone, circumstances might arise to render the inspection of others necessary, and from their inability to follow out transactions in the books, suspicions would probably be engendered for which there was no real foundation. Hence the necessity for the adoption of certain recognized and approved systems, which, being plain and easily understood, must prove satisfactory to all concerned.

Book-keeping, when conducted upon sound principles, is invaluable; it not only shows the general result of a commercial career, but admits of analysis, by which the success or failure, the value or utter worthlessness of its component parts, or each particular transaction, can be easily ascertained. In a word, on the one hand it promotes order, regularity, fair dealing, and honourable enterprise; on the other, it defeats dishonesty, and preserves the integrity of man when dealing with his fellows.

It would be difficult, and perhaps of little importance, to trace the origin of book-keeping. It was certainly known to the ancients (see Pliny, lib. ii. cap. 7); and Cicero seems to have had bill transactions between Rome and Athens when he arranged for his son's education without the necessity of having to remit money (see *Epis. ad Att.* xii. 24; xv. 25), which infers some kind of book-keeping. Kelly, however, who wrote on the subject in 1805, asserts, and it is not disputed, that a friar, named Lucas di Borgo, whose work on algebra was the first to appear in print, was the first to write a treatise upon book-keeping, and this was published at Venice in 1495.

This work was followed by many others, possessing considerable merit, but so complex as to make them useless. After a time the mercantile community became alive to the fact that a practical system would be preferable to the theoretical suggestions of writers who were utterly ignorant of commercial matters; and men, more or less connected with trade, began to write on the subject. The incubus of prolixity, however, still clung to them, conciseness of style seeming an impossibility, and the great fundamental principles of the art were so smothered by rules and explanations—the volumes sometimes containing 500 or 600 pages—that the difficulty was how to apply them; hence the need of still greater simplicity and improvement.

In 1796 Mr E. T. Jones of Bristol devised a plan "for keeping books correctly," breaking the ice with a treatise which is still held in very high estimation. After that a great improvement is visible in the writings of authors on this important subject, as in those of Benjamin Booth (1789), Hamilton (1820), Jones (2d treatise, 1821, 3d treatise, 1831), C. Morrison (1823), W. and R. Chambers, Edinburgh,—the most of them, those of Jones excepted, being elementary works, more particularly adapted to schools, and illustrating the principles of the science by the example of one set of books adapted to foreign trade. In F. H. Carter's *Practical Book-keeping, adapted to Commercial and Judicial Accounting* (3d ed. 1875), which gives a great variety of forms and sets of books, the recognized

systems of book-keeping are practically applied, so as to enable any one, without difficulty, to acquire a thorough knowledge of the science.

The questions to which a satisfactory system of book-keeping gives the trader ready and conclusive answers are such as relate—1. To the extent to which his capital and credit will entitle him to transact business; 2. To the assurance he has that all his obligations are honestly fulfilled; 3. To the ascertainment of the success or failure of his commercial dealings, and the position of his affairs from time to time.

There are three recognized systems of book-keeping, namely, by "single entry," "double entry," and the "mixed method."

I. Single Entry.—This system is denoted by its name, transactions being posted singly, or only once, in the ledger. Three books are generally kept—the cash book, day book, and ledger, although the first-named is not essential, the cash entries being passed through the day book. Its only use is to check the balance of cash in hand. In the day book are entered daily all the purchases and sales, whether for cash or credit; and all the credit entries are then transferred to accounts opened in the ledger, that is, all goods sold on credit are charged against the customers, and what are purchased are carried to the credit of parties supplying them. In the same way, when cash is received from a customer for goods sold on credit, it is posted to his account, and the reverse entry is made when a trader pays for the goods he has bought. Thus it will be seen that only personal accounts are entered in the ledger.

To frame a balance sheet, or state of affairs, on this system, the book-keeper brings down the balances due by customers to him, also his stock of goods as valued, and the cash he may have in hand, on the *left-hand side* of the sheet; whilst on the *right-hand side* he enters the balances still due by him for goods supplied, or money lent to him, and the capital, if any, with which he commenced business. The difference between the amounts of the two columns is either profit or loss; if profit, the merchant's capital is increased to that extent, and if loss, then he is so much the poorer.

The following skeleton balance sheet will give a better idea of the working and ultimate results of the system:—

Balance Sheet by Single Entry.

Assets.	£	s.	d.	*Liabilities.*	£	s.	d.
To Sundry Customers for Goods sold, per List......	216	10	0	By sundry Tradesmen for Goods supplied, per List.	184	7	8
,, Goods in Stock, per Inventory and Valuation..	314	9	6	,, Capital put into the Business........................	300	0	0
,, Cash in hand..	3	4	9				
					484	7	8
				,, Profit on Business to date	49	16	7
	534	4	3		534	4	3

It will be observed that as the assets exceed the liabilities (including capital) by £49, 16s. 7d., that sum, being profit, must be added to capital; if, in the next or following years, any loss should emerge, as a matter of course such deficiency must be deducted from the trader's capital. The advantages of single entry are simplicity and easy adaptation to small retail trades, as the ledger contains only outstanding debts due to or by the trader. The disadvantage is in the difficulty of ascertaining the profits or losses on various goods, or on the several departments of a business.

II. Double Entry.—It is now universally admitted that this system is the best adapted for heavy, responsible, or speculative trades, for foreign trade especially, and for extensive mercantile concerns. As its name implies, it so far differs from the system already described, that every transaction must be recorded doubly in the ledger, that is to say, accounts must be opened in that book, to which all entries in the subsidiary books, after being journalized, are twice carried, to the debit of one account and the credit of another. To illustrate this, let us assume that a merchant speculates in cotton, and purchases so many bales from John Bevan and Co. upon credit; he debits "Cotton account," and credits "John Bevan and Co." He does not pay for it in cash, but gives his bill at three months for the amount; John Bevan and Co. are debited with the bill, and "Bills Payable" are credited. He then sells the whole lot of cotton for cash to Cairns, Brown, and Co., debiting "Cash" and crediting "Cotton account." Lastly, he retires or pays the bill granted to John Bevan and Co., debits "Bills Payable," and credits "Cash." We will now put all these transactions into a "journal," posting therefrom to a "ledger," and so illustrate book-keeping by double entry.

	To Cash in hand..........................	851	0	0		By P. and L................................	851	0	0

It may be alleged that there are many unnecessary entries, involving too much trouble and waste of time, in bringing out the above results; but upon examination of the several accounts the great simplicity and utility of double entry is evident. For instance, "Cotton" account shows the actual result of the speculation per "Mary Jane;" "John Bevan and Co.'s" account exhibits the whole transaction with them, and how it was settled; "Bills Payable" account at once shows that the cotton bill is retired or paid; and "Cash" account declares a balance of £851 in cashier's hands, being the actual profit on the cotton, as further shown in "Profit and Loss" account.

An infinity of examples might be *given*, but the above will be a sufficient illustration. A *brief* outline, however, of the principal books required in this system may be introduced.

1. The CASH BOOK.—In this most important book *every cash* transaction must be entered of its proper date, and under its distinctive ledger heading, so as to give facility in journalizing; any balance thereon must be *cash* in hand, and should agree with the balance on "Cash account" in the ledger.

2. The DAY *or* WASTE BOOK.—This book records the daily transactions of every description in the rough, which, when properly arranged and *classified*, are written into the journal, and posted from thence to the ledgers.

3. The JOURNAL.—This may be called the mainspring of the system, and is *sometimes* called the "*posting medium*," as in it every transaction of *the* business is properly *recorded* before being again distributed *into* the ledger. There are *several* forms of journal, but the simplest and best is that of which a specimen has been given, with the addition of a column for the *insertion* of ledger folios when posted. *It* will be observed that the *debit* entries are in one column and the *credit* entries in *another*; if, therefore, the summations of these agree, and the entries *therein* embraced are correctly posted to the debit and credit *of accounts* in the ledger, the double entry is correct, and the books of the concern, no matter how multitudinous the entries may be, must come to a true balance.

4. The LEDGERS.—These are important books, as they are the final recipients of every transaction of the concern, branched out or distributed into certain heads or accounts which tell their own history; and if unbalanced, must exhibit a difference either in favour of the business as an "Asset," or against it as a "Liability." The usual plan is to have only *one* ledger, embracing every account, but in large concerns there are debit and credit ledgers, and generally a private ledger, which is accessible to partners only.

The advantages of double entry are many—(1.) Unless the debit balances exactly correspond with the credits the books are wrong, and the error must be discovered by comparison; (2.) The discovery of such errors is more easily *accomplished* than in any other system; (3.) Accounts can be readily analyzed; and (4.) The profit or loss on *distinct* transactions can be ascertained without difficulty. The disadvantages are—(1.) More *manual* labour required in transcribing the journal and posting therefrom than *in* other systems; and (2.) There is not the same privacy, as profits and losses can be seen at a glance by any one having access to the ledger. Nevertheless, no other system as yet devised can at all compare with that by double entry.

III. MIXED METHOD.—This system is now extensively adopted by such *companies* and firms as begrudge the time expended in journalizing, and are of opinion that double entry is too elaborate, when the same results can be arrived at by a more direct and less laborious *plan*. There is this identity, however, between the systems, that every transaction must be recorded *somewhere*, and eventually twice posted, as in double entry, *but* without the medium of a journal; moreover, the entries are fewer, summations and not specific items being *posted*, and what would be the daily labour under one system is reserved under this for a monthly or perhaps *longer* period. There are only three books required for this system to which we need draw attention, and in doing so we will point out in what respect they differ from those kept in single and double entries.

1. Cash Book.—Every entry is posted from this book, but not all to the ledger as in double entry—"Charges" being posted to the day book. It is not journalized, and is in itself a ledger, as it contains the bank account, and reports its own cash balance. On the other hand, it is unlike the "Cash" of single entry, because every entry is posted somewhere, whereas by the latter system only personal accounts are carried to the ledger.

2. Day Book.—This book also exhibits a marked difference between the journal of double entry and the day book of single entry. The journal is simply a posting medium, and when its use is served is almost valueless. The single entry day book, on the other hand, is only a posting medium to a certain extent, as it does not embrace all transactions; but in this system the day book unites the characteristics of journal and ledger, and also becomes in itself a profit and loss account, as by deducting the amount of charges from the amount of the business fees (say for solicitors' books) *the profit on said business is shown.*

3. The Ledgers.—These books also lose their completeness under the mixed method. It has already been shown that in double entry every amount must appear in the ledger, and in single entry that only personal accounts are posted in it. By this system not only are all personal accounts included, but those applicable to "Capital," to "Banks," "Bills," &c.; whilst, on the other hand, such accounts as "Profit and Loss," "Charges," and "Cash" are excluded.

It would be out of place here to dwell on the many intricacies of this subject, or on the difficulties which are constantly presenting themselves even to the most practical men. With a thorough knowledge of the art, however, and that patience and perseverance so essential to the calling of a book-keeper, the gravest impediments are overcome, and everything becomes simple and plain. Our sole object having been to show the utility of book-keeping as a science, and the peculiar features of existing systems with their advantages and disadvantages, it is unnecessary to enter more minutely into details by describing subsidiary books or forms of accounts, as these are only so many materials out of which the fabric of book-keeping is erected, and can be seen in any counting-house or mercantile establishment where regular systems are adopted. (F. H. C.)

BOOLE, George, one of the most original logicians and mathematicians whom England has produced, was born in Lincoln on the 2d of November 1815. His father was a tradesman of limited means, but of studious character and active mind. Being especially interested in mathematical science the father gave his son early instruction in the rudiments of the science he was so greatly to advance; but it is remarkable that the extraordinary mathematical powers of George Boole did not manifest themselves in early life. The classical languages formed at first the favourite subject of his studies. Not until the age of seventeen years did he attack the higher mathematics, and his progress was much retarded by the want of efficient help.

When about sixteen years of age he became assistant-master in a private school at Doncaster, and he maintained himself to the end of his life in one grade or other of the scholastic profession. Few distinguished men, indeed, have had a less eventful life. Almost the only changes which can be called events are his successful establishment of a school at Lincoln, its removal to Waddington, his appointment in 1849 as professor of mathematics in the Queen's College at Cork, and his marriage in 1855 to Miss Mary Everest.

To the public Boole was known only as the author of numerous abstruse papers on mathematical topics, and of three or four distinct publications which have become standard works. His earliest published paper was one upon the "Theory of Analytical Transformations," printed in the *Cambridge Mathematical Journal* for 1839, and it led to a friendship between Boole and D. F. Gregory, the editor of the journal, which lasted until the premature death of the latter in 1844. A long list of Boole's memoirs and detached papers, both on logical and mathematical topics, will be found in the *Catalogue of Scientific Memoirs* published by the Royal Society, and in the supplementary volume on *Differential Equations*, edited by Mr Todhunter. To the *Cambridge Mathematical Journal* and its successor, the *Cambridge and Dublin Mathematical Journal*, Boole contributed in all twenty-two articles. In the third and fourth series of the *Philosophical Magazine* will be found sixteen papers. The Royal Society printed six important memoirs in the *Philosophical Transactions*, and a few other memoirs are to be found in the *Transactions of the Royal Society of Edinburgh* and of the *Royal Irish Academy*, in the *Bulletin de l'Académie de St Pétersbourg* for 1862 (under the name G. Boldt, vol. iv. pp. 198–215), and in *Crelle's Journal*. To these lists should be added a paper on the mathematical basis of logic, published in the *Mechanic's Magazine* for 1848. The works of Boole are thus contained in about fifty scattered articles and a few separate publications.

Only two systematic treatises on mathematical subjects were completed by Boole during his lifetime. The well-known *Treatise on Differential Equations* appeared in 1859, and was followed, the next year, by a *Treatise on the Calculus of Finite Differences*, designed to serve as a sequel to the former work. These treatises have become the standard text-books on the important branches of mathematics in question, and Boole, in composing them, seems to have combined elementary exposition with the profound investigation of the philosophy of the subject in a manner hardly admitting of improvement. To a certain extent these works embody the more important discoveries of their author. In the 16th and 17th chapters of the *Differential Equations* we find, for instance, a lucid account of the general symbolic method, the bold and skilful employment of which led to Boole's chief discoveries, and of a general method in analysis, originally described in his famous memoir printed in the *Philosophical Transactions* for 1844. Boole was one of the most eminent of those who perceived that the symbols of operation could be separated from those of quantity and treated as distinct objects of calculation. His principal characteristic was perfect confidence in any result obtained by the treatment of symbols in accordance with their primary laws and conditions, and an almost unrivalled skill and power in tracing out these results.

During the last few years of his life Boole was constantly engaged in extending his researches with the object of producing a second edition of his *Differential Equations* much more complete than the first edition; and part of his last vacation was spent in arduous study in the libraries of the Royal Society and the British Museum for the purpose of acquiring a complete knowledge of the less accessible original memoirs on the subject. It must be always a matter of regret that this new edition was never completed. Even the manuscripts left at his death were so incomplete that Mr Todhunter, into whose hands they were put, found it impossible to use them in the publication of a second edition of the original treatise, and wisely printed them, in 1865, in a supplementary volume.

Profound and important as were Boole's discoveries in pure mathematics, his writings on logic may be considered as still more original. With the exception of De Morgan, he was probably the first English mathematician since the time of Wallis who had also written upon logic; and his wholly novel views of logical method were due to the same profound confidence in symbolic reasoning to which he had successfully trusted in mathematical investigation. From the preface to his *Mathematical Analysis of Logic*, printed as a separate tract in 1847, we learn that speculations concerning a calculus of reasoning had at different times occupied Boole's thoughts, but it was not till the spring of 1847 that a memorable logical controversy led him to put his ideas into a definite form. Boole afterwards regarded this pamphlet as a hasty and imperfect exposition of his

logical system, and he desired that his much larger work, *An Investigation of the Laws of Thought, on which are founded the Mathematical Theories of Logic and Probabilities*, published in 1854, should alone be considered as containing a mature statement of his views. Nevertheless, there is a charm of originality about his earlier logical work which no competent reader can fail to appreciate, and the introduction gives striking evidence of his profound views and wide reading.

It is not easy to give in a few words a correct notion of Boole's logical system, and only those who are conversant with the principles of symbolical reasoning can exactly apprehend his position. He did not regard logic as a branch of mathematics, as the title of his earlier pamphlet might be taken to imply, but he pointed out such a deep analogy between the symbols of algebra and those which can be made, in his opinion, to represent logical forms and syllogisms, that we can hardly help saying that logic is mathematics restricted to the two quantities, 0 and 1. By unity Boole denoted the universe of thinkable objects; literal symbols, such as x, y, z, v, u, &c., were used with the elective meaning attaching to common adjectives and substantives. Thus, if x = horned, and y = sheep, then the successive acts of election represented by x and y, if performed on unity, give the whole of the class *horned sheep*. Boole showed that elective symbols of this kind obey the same primary laws of combination as algebraical symbols, whence it followed that they could be added, subtracted, multiplied, and even divided, almost exactly in the same manner as numbers. Thus, $1-x$ would represent the operation of selecting all things in the world except *horned things*, that is, *all not horned things*, and $(1-x)(1-y)$ would give us *all things neither horned nor sheep*. By the use of such symbols propositions could be reduced to the form of equations, and the syllogistic conclusion from two premises was obtained by eliminating the middle term according to ordinary algebraic rules.

Still more original and remarkable, however, was that part of his system, fully stated in his *Laws of Thought*, which formed a general symbolic method of logical inference. Given any propositions involving any number of terms, Boole showed how, by the purely symbolic treatment of the premises, to draw any conclusion logically contained in those premises. The second part of the *Laws of Thought* contained a corresponding attempt to discover a general method in probabilities, which should enable us from the given probabilities of any system of events to determine the consequent probability of any other event logically connected with the given events. Soon after its publication this method was the subject of a controversy in the *Philosophical Magazine*; but it cannot be said that the exact value of this part of his works has ever been clearly ascertained.

It is often supposed that mathematicians are deficient in judgment and knowledge of other matters. In Boole this was not the case; for though he published little except the mathematical and logical works already mentioned, his acquaintance with general literature was wide and deep. Dante was his favourite poet, and he preferred the *Paradiso* to the *Inferno*. The metaphysics of Aristotle, the ethics of Spinoza, the philosophical works of Cicero, and many less celebrated works of a kindred character, were also frequent subjects of study. His reflections upon scientific, philosophical, and religious questions are to be mainly gathered from four addresses upon *The Genius of Sir Isaac Newton*, *The Right Use of Leisure*, *The Claims of Science*, and *The Social Aspect of Intellectual Culture*, which he delivered and printed at different times.

The personal character of Boole inspired all his friends with the deepest esteem. He was marked by the modesty of true genius, and his life was given to the single-minded pursuit of truth. Though he received a royal medal for his memoir of 1844, and the honorary degree of LL.D. from the University of Dublin, it may be said that he neither sought nor received the ordinary rewards to which his discoveries would entitle him.

On the 8th of December 1864, in the full vigour of his intellectual powers, Boole died of an attack of fever, ending in suffusion on the lungs An excellent sketch of his life and works, by the Rev. R. Harley, F.R.S., to which the present writer is indebted for many particulars, is to be found in the *British Quarterly Review* for July 1866, No. 87. (W. S. J.)

BOOM, a town of Belgium, in the province of Antwerp, and 12 miles S. of that city, at the junction of the Brussels Canal with the River Rupel. It is an active industrial town, possessing tanneries, salt-works, starch-factories, breweries, and brick and tile works, and carries on a considerable trade. Population of the commune, 10,064.

BOOMERANG, a missile instrument of the Australian aborigines, in the use of which they are very dexterous. It consists of a piece of hard wood, with the curve of a parabola, and is about 2 feet long, $2\frac{1}{2}$ inches broad, $\frac{1}{3}$ inch thick, and rounded at the extremities. One side is flat, the other is rounded, and it is brought to a bluntish edge. It is discharged with the hand by one end, the convex edge being forward and the flat side upwards. After advancing some distance, and ascending slowly in the air with a quick rotatory motion, it begins to retrograde, and finally falls to the ground behind the thrower. A weapon of similar form, but wanting the return flight, has been found in use among savage tribes both in India and Africa. A very full comparative account of the boomerang is contained in Colonel A. H. Lane Fox's lecture on "Primitive Warfare" (*Jour. of the Royal United Service Institution*, vol. xii. No. 51).

BOOTH, BARTON, an English tragedian, descended from an ancient family in Lancashire, was born in 1681. He was educated at Westminster school under the celebrated Dr Busby, and his success in the Latin plays, customarily performed there by the scholars, gave him an inclination for the stage. He was intended for the church; but at seventeen years of age he ran away from school, and after some vicissitudes obtained employment in a theatrical company in Dublin. His first appearance was hailed with applause; and he continued to improve daily. After two successful campaigns in Ireland he returned to his native country, having first reconciled himself to his friends. Betterton, to whom he had an introduction, received him with great cordiality, and gave him all the assistance in his power. His success at London was complete, and he established his reputation as only second to his great instructor. He was indebted to a happy coincidence of merit and chance for the celebrity which he at length attained in the character of Cato. The Whigs, in favour of whose principles Addison's tragedy had been written, thought it their duty to support it strongly; while the Tories, at every passage susceptible of a popular turn, were no less vehement in their approbation, and at the close the actor was presented by Lord Bolingbroke with a purse of fifty guineas, "as a slight acknowledgment of his honest opposition to a perpetual dictator, and his dying so bravely in the cause of duty." Booth was twice married,—first to a daughter of Sir William Barkham, Bart., and afterwards to Miss Hester Santlow, an actress of great merit. During the twenty years of his management the theatre was in the greatest credit; and his death, which happened on the 10th of May 1733, contributed not a little to its decline. Booth was a man of excellent character, and greatly esteemed for his amiability and goodness of heart.

(*See Memoirs of the Life of Barton Booth*, 1733; Cibber, *Lives and Characters of the most Eminent Actors*, &c., pt. i., 1753.)

BOOTHIA FELIX, a peninsula of British North America, between lat. 69° and 72° N., and long. 92° and 97° W. It was discovered by Captain (afterwards Sir James) Ross, in 1830, and was named after Sir Felix Booth, who had fitted out the expedition. It forms the western side of the gulf of the same name into which Prince Regent's Inlet leads from Baffin's Bay. From the American shore it is almost separated by lakes and inlets; and a narrow channel known as Bellot Strait intervenes between it and North Somerset Island, which was discovered by Sir E. Parry in 1819. The peninsula is not only interesting for its connection with the Franklin expedition and the Franklin search, but is of scientific importance from the north magnetic pole having been first distinctly localized there by Ross.

BOPP, Francis, glottologist, was born at Mainz on the Rhine, September 14, 1791. In consequence of the political troubles of that time, his parents removed to Aschaffenburg, in Bavaria, where Francis received a liberal education at the Lyceum. It was here that his attention was drawn to the languages and literature of the East by the eloquent lectures of Carl J. Windischmann, who, with Creuzer, Görres, and the brothers Schlegel, was full of enthusiasm for Indian wisdom and philosophy. And further, Fr. Schlegel's book, *Ueber die Sprache und Weisheit der Inder* (Heidelberg, 1808), which was just then exerting a powerful influence on the minds of German philosophers and historians, could not fail to stimulate also Bopp's interest in the sacred language of the Hindus. He was, however, too strictly trained in grammatical and philological studies, and too eager for the scientific analysis of language, to allow the clearness of his judgment to be warped by the romantic and speculative predilections of Windischmann and Fr. Schlegel. In 1812 he went to Paris at the expense of the Bavarian Government, with a view to devote himself vigorously to the study of Sanskrit. There he enjoyed the society of such eminent men as Chézy, S. de Sacy, Langlès, and, above all, Al. Hamilton, who had acquired, when in India, a respectable acquaintance with Sanskrit, and had brought out, conjointly with Langlès, a descriptive catalogue of the Sanskrit manuscripts of the Imperial library. At that library Bopp had access not only to the rich collection of Sanskrit manuscripts, most of which had been brought from India by Father Pons early in the 18th century, but also to the Sanskrit books which had up to that time issued from the Calcutta and Serampore presses.

The first fruit of his four years' study in Paris appeared at Frankfort-on-the-Main in 1816, under the title *Ueber das Conjugationssystem der Sanskritsprache in Vergleichung mit jenem der Griechischen, Lateinischen, Persischen, und Germanischen Sprache*, and it was accompanied with a preface from the pen of Windischmann, bearing date 16th May of that year. In this first book, Bopp entered at once on the path on which the philological researches of his whole subsequent life were concentrated. It was not that he wished to prove the common parentage of Sanskrit with Persian, Greek, Latin, and German, for that had long been established; but his object was to trace the common origin of their grammatical forms, of their inflexions from composition,—a task which had never been attempted. By a historical analysis of those forms, as applied to the verb, he furnished the first trustworthy materials for a history of the languages compared.

After a brief sojourn in Germany, Bopp came to London, where he made the acquaintance of Wilkins and Colebrooke, and became the friend of Wilhelm von Humboldt, then Prussian ambassador at the court of St James's, to whom he gave instruction in Sanskrit. He brought out, in the *Annals of Oriental Literature* (London, 1820, pp. 1-65), an essay entitled "Analytical Comparison of the Sanskrit, Greek, Latin, and Teutonic Languages," in which he extended to all parts of the grammar what he had done in his first book for the verb alone. He had previously published a critical edition, with a Latin translation and notes, of the story of *Nala and Damayanti* (London, 1819), the most beautiful episode of the Mahâbhârata, which he had with genial tact culled from the tangled labyrinth of that gigantic epic. Other episodes of the Mahâbhârata—*Indralokâgamanam*, and three others, Berlin, 1824; *Diluvium*, and three others, Berlin, 1829; and a new edition of *Nala*, Berlin, 1832—followed in due course, all of which, with A. W. Schlegel's edition of the *Bhagavadgîtâ*, 1823, proved excellent aids in initiating the early student into the reading of Sanskrit texts. On the publication, in Calcutta, of the whole Mahâbhârata, Bopp discontinued editing Sanskrit texts, and confined himself thenceforth exclusively to grammatical investigations.

After a short residence at Göttingen, Bopp was, on the recommendation of W. von Humboldt, appointed to the chair of Sanskrit and comparative grammar at Berlin in 1821, and was elected member of the Royal Prussian Academy in the following year, both which posts he held up to his death, Oct. 23, 1867. In his quality as Sanskrit professor he brought out, in 1827, his *Ausführliches Lehrgebäude der Sanskrita-Sprache*, on which he had been engaged since 1821. A new edition, in Latin, was commenced in the following year, and completed in 1832. A shorter grammar (*Kritische Grammatik der Sanskrita-Sprache in kürzerer Fassung*) has run through three editions (Berlin, 1834, 1845, 1863). At the same time he compiled a Sanskrit and Latin glossary (1830) in which, more especially in the second and third editions (1847 and 1867), account has also been taken of the cognate languages. His chief activity, however, centred on the elaboration of his *Comparative Grammar*, which appeared in six parts at considerable intervals (Berlin, 1833, 1835, 1842, 1847, 1849, 1852; 1511 pages in small 4to), under the title *Vergleichende Grammatik des Sanskrit, Zend, Griechischen, Lateinischen, Litthauischen, Altslavischen, Gothischen, und Deutschen.* How carefully this work was matured may be gathered from the series of monographs printed in the *Transactions of the Berlin Academy* (1824 to 1831), by which it was preceded. They bear the general title, *Vergleichende Zergliederung des Sanskrits und der mit ihm verwandten Sprachen.* Two other essays (on the "Numerals," 1835) followed the publication of the first part of the *Comparative Grammar.* The Old-Slavonian began to take its stand among the languages compared from the second part onwards. At the instance of the earl of Ellesmere (then Lord Francis Egerton) the work was translated into English by Mr E. B. Eastwick (3 vols., 1845; second edition, 1854). A second German edition, thoroughly revised (3 vols., 1856–1861), comprised also the Old-Armenian. From this edition an excellent French translation was made by Professor Michel Bréal, which came out in 5 vols. in 1866, *ff.* A third German edition has been published since the author's death, in 1871, *ff.*

The task which Bopp endeavoured to carry out in his *Comparative Grammar* was threefold,—to give a description of the original grammatical structure of the languages as deduced from their intercomparison, to trace their phonetic laws, and to investigate the origin of their grammatical forms. The first and second points were subservient to the third. As Bopp's researches were based on the best available sources, and incorporated every new item of information that came to light, so they continued to widen and deepen in their progress. Witness his monographs on the vowel system in the Teutonic languages (1836), on the Celtic

languages (1839), on the Old-Prussian (1853) and Albanian languages (1854), on the accent in Sanskrit and Greek (1854), on the relationship of the Malayo-Polynesian with the Indo-European languages (1840), and on the Caucasian languages (1846). In the two last-mentioned the impetus of his genius had led him on a wrong track. They show the rocks against which the student of comparative philology has to guard.

As for the charge that has been made against Bopp of neglecting the study of the native Sanskrit grammars, every excuse ought to be made in his favour. In those early days of Sanskrit studies the requisite materials were not accessible in the great libraries of Europe; and if they had been, they would have absorbed his exclusive attention for years, while the grammars of Forster, Wilkins, and Colebrooke, from which his grammatical knowledge was derived, were all based on native grammars. The further charge that Bopp, in his *Comparative Grammar*, gave undue prominence to Sanskrit may be disproved by his own words; for, as early as the year 1820, he gave it as his opinion that frequently the cognate languages serve to elucidate grammatical forms lost in Sanskrit (*Annals of Or. Lit.*, i. 3),—an opinion which he has further developed in all his subsequent writings. In his translations from the Sanskrit Bopp was not successful. He seems to have felt this himself; for, after the publication, in 1838, of his metrical translation of the *Story of Nala*, he resigned that task to more skilful hands.

The method of tracing the life and growth of language, so successfully applied by Bopp in the case of the Indo-European languages, has become the corner stone on which all modern linguistic science rests. His researches, carried with wonderful penetration into the most minute and almost microscopical details of linguistic phenomena, have led to the opening up of a wide and distant view into the original seats, the closer or more distant affinity, and the tenets, practices, and domestic usages of the ancient Indo-European nations, and form the only safe basis on which further investigations in each direction are possible. The outlines of his great work had been distinctly traced by him in his very first publication, from which the science of comparative grammar may truly be said to date. In grateful recognition of that fact, on the fiftieth anniversary of the date of Windischmann's preface to that work, a fund called *Die Bopp-Stiftung*, for the promotion of the study of Sanskrit and comparative grammar, was established at Berlin, to which liberal contributions were made by his numerous pupils and admirers in all parts of the globe.

Bopp was specially favoured by fortune in living to see the results of his labours everywhere accepted, and his name justly celebrated. But the sun that gilds the writer's pen did not shine upon him, and he died a poor man,—by his genuine kindliness and unselfishness, his devotion to his family and friends, and his rare modesty, endeared to all who knew him. (*Bréal's Translation of Bopp's Comp. Gr.*, vol. i., introduction; Th. Benfey, *Geschichte der Sprachwissenschaft*, 1869; A. Kuhn in *Unsere Zeit*, Neue Folge, iv. 1, 1868.)

BORAX, the biborate of sodium ($Na_2B_4O_7$), a substance found in commerce under the two different forms of ordinary or prismatic borax, which contains ten equivalents of water of crystallization, and octahedral or jeweller's borax, which has only five molecules of water in its composition. The former, which is the variety commonly met with, occurs as a natural product in various parts of the world. In former times crude borax was procured chiefly from Thibet, whence it came by way of India under the name of tincal. It also is found in other parts of Central Asia, at Halberstadt in Transylvania, in Canada, and in Peru; and in recent years an important source of the mineral has been discovered near the Clear Lake in California, in a body of water now called the Borax Lake. In very dry seasons the water almost entirely disappears from the basin of the Borax Lake, which is situated in a region containing hot springs and the remains of volcanic action. In 1863, when the lake measured 4000 feet long, 1800 feet across at its widest part, and about 3 feet deep, the water was found to contain 2401·56 grains of solid matter per gallon, of which 535·08 grains represented crystallized borax. The bed of the lake is occupied with a deposit of borax crystals, which are obtained by sinking caissons, pumping out the water, and digging up the deposit. Californian crude borax is fit for use by assayers and others without undergoing any purification; but that obtained from Thibet contains a greenish encrusting matter of a soapy consistence which has to be separated before the material is fit for use under the name of refined borax.

The supply of borax is, however, more largely derived by artificial means from boracic or boric acid, or from salts in which that acid occurs, than from these natural sources. Boracic acid is found among the ejecta around the craters of some volcanoes, and it is found in jets of vapour which stream forth from fissures in the earth in regions of volcanic disturbance. The chief source of boracic acid at the present day is found in the Maremma of Tuscany, an extensive and desolate track of country embracing an area of about forty miles, over which jets of vapour and heated gases (*soffioni*) and springs of boiling water spurt out from numerous chasms and fissures. The Maremma is disturbed by frequent volcanic shocks; at some points the mouths of the fissures open direct into the air, at others they are covered by small muddy lakes (*lagoni*). In addition to a small impregnation of boracic acid the soffioni contain ammoniacal vapour, to fix and obtain which the gases at some works are led through sulphuric acid. For obtaining the boracic acid a series of basins or artificial lagoni are formed over the soffioni, so arranged that water to be charged with the acid is conveyed by gravitation from the first to the last of the series. Water is led into the highest and by the action of the heated gases it is soon in a state of ebullition. After being so left for about a day it is drawn off into the second, where it remains under like circumstances for the same period, and so to the end of the series, when the water should contain nearly 2 per cent. of boracic acid. The mechanical impurities being allowed to subside, the liquor is then run into evaporating pans, shallow lead-lined vessels, heated by the gases from the soffioni themselves. The evaporating pans are worked on a continuous system, similar to the lagoons; the liquor placed in the upper being concentrated down to half its original bulk is run into the second, and so on till it reaches a degree of concentration fit for crystallizing out the acid. In recent years artificial soffioni have been formed by boring through the rock till some of the numerous chasms or chambers, with which the interior is honey-combed, are reached, when immediately all the phenomena of a boracic soffione are established. From some of these artificial soffioni issues water of sufficient richness in acid to be led there direct to the evaporating pans. Similar emanations of volcanic vapours and boracic acid have been discovered in Nevada, United States. Boracic acid is also obtained from boronatrocalcite (Ulexite or Hayesine), a double salt of sodium and calcium, of which extensive deposits exist in the neighbourhood of the nitrate of soda beds of Chili and Peru. It is very variable in constitution and condition of purity. Similar deposits are found in California, Nevada, and Nova Scotia, and from the West Coast of Africa is received a borate of lime bearing the name of rhodizite. The boronatrocalcite, or borate of lime, as it is called in commerce, is applied in its unrefined condition

to many uses for which borax is employed. In 1855 Dr T. Richardson patented a process for using the picked and washed boronatrocalcite as a substitute for borax in the glass manufacture and preparation of pottery glazes. It is, however, chiefly employed as a source of boracic acid, and there are also several methods of obtaining borax direct from the compound salt.

Commercial boracic acid usually contains a considerable percentage of sulphates of ammonium, magnesium, and calcium besides other impurities. To prepare borax from this acid, from 110 to 120 parts of crystallized sodium carbonate are required for 100 parts of boracic acid. The soda is dissolved in a lead-lined vessel heated with steam, to which the boracic acid is added in repeated charges. The vessel is covered and the carbonate of ammonia given off is led into a solution of sulphuric acid and fixed. For the production of ordinary or prismatic borax the solution is brought to a strength of 20° to 22° Baumé (1·161 to 1·180 sp. gr.) and allowed to cool down as slowly as possible, so that the crystals may assume the large size demanded in commerce. Octahedral borax is deposited when a solution indicating 30° Baume (sp. gr. 1·264) is slowly cooling down from 79° to 56° C. Below this point the formation of ordinary borax takes place.

Under the blowpipe borax parts with its water, and melts into a clear-glass which has the peculiar property of dissolving many metallic oxides, and thereby exhibiting characteristic colours, on which account it is of great value in blowpipe analysis. The same property also renders it a valuable material for pottery glazes and enamels, and as it adheres closely to clean surfaces of metal and prevents their oxidation under high heat, it is indispensable for use in hard soldering, and is largely employed in brass manufactures. It is also one of the ingredients employed in glass-making. Borax forms with oils and fats a soap which has been proposed as a detergent; but experiments conducted by the late Professor Thomas Anderson of Glasgow show that it has a more corrosive influence on fibres than common soap. In Belgium powdered borax is used in domestic washing, with the object of economizing soap. Borax is used in medicine as an external application in skin diseases, and the preparation known as *mel boracis* is a useful gargle in ulceration of the mouth and throat. In Sweden boracic acid is extensively employed for the preservation of meat and milk; and while it forms an efficient antiseptic, food prepared with it is said to be perfectly fit for use. A very beautiful pigment, now much used in calico-printing, under the name of Guignet's green, is a borate of chromium.

BORDA, JEAN CHARLES, mathematician and nautical astronomer, was born at Dax on the 4th May 1733. He studied at La Flèche, and at an early age obtained a commission in the cavalry. In 1756 he presented a valuable paper to the Academy of Sciences, who elected him a member. He was present at the battle of Hastembeck, and soon afterwards joined the naval service. He visited the Azores and the Canary Islands, of which he constructed an admirable map. In 1782 his frigate was taken by a British squadron; he himself was carried to England, but was almost immediately released on parole, and returned to France. He died on the 20th February 1799. Borda was an admirable mathematician, and contributed a long series of valuable memoirs to the Academy of Sciences. His researches in hydrodynamics were highly useful for marine engineering, while the reflecting and repeating circles, as improved by him, were of great service in nautical astronomy. He was associated with Delambre and Méchain in the attempt to determine an arc of the meridian, and the greater number of the instruments employed in the task were invented by him. (See Biot, "Notice sur Borda" in the *Mém. de l'Acad. des Sciences*, iv.)

BORDEAUX, one of the finest and wealthiest commercial cities of France, formerly the capital of Guienne and Bordelais, and now the chief town of the department of Gironde. It is situated 370 miles S.E. of Paris, in 44° 50′ N. lat. and 0° 25′ W. long., on the left bank of the Garonne, about 60 or 70 miles from its mouth, and in the midst of an extensive plain which comprises the district of Médoc, well-known for its red wines. Opposite the town the river makes a semicircular curve, and widens out into an extensive basin, which serves as a harbour, and is lined with quays on both sides for a distance of three miles. Vessels of 800 tons can come up to the town, and ships of the greatest ordinary tonnage have depth enough as far as Pauillac, about 35 miles from the mouth of the river. The basin is crossed by a magnificent stone bridge of 17 arches, 1534 feet long, which was built in 1821, and remained in the hands of a company till 1861 when it was declared free. A short distance further up the river is spanned by a railway bridge. Few cities in Europe can show such a striking water-front as Bordeaux; and though the streets of the older part are narrow and mean, those of the newer portions are wide and well paved, and contain handsome houses and public buildings. The principal square is the Place des Quinconces, which is adorned with statues of Montaigne and Montesquieu. Among the ecclesiastical buildings the most important are the cathedral of Saint André, a fine Gothic structure with two spires 160 feet high; the church of Saint Michel, founded in 1160, and formerly remarkable for a spire 319 feet in height, destroyed by a storm in 1768; Saint Croix, probably in existence before the 7th century, restored in 1864–5; Saint Paul, built by the Jesuits in 1676; and the church of the Collége Royal, in which is the tomb of Montaigne. The great intellectual activity of the city may be seen from the fact that it possesses an academy (with faculties of theology, law, science, and literature), a medico-pharmaceutical school, a lyceum, a school for deaf-mutes, a normal school, and a school of navigation; numbers among its societies an academy of sciences, arts, and belles lettres, a medical society (founded in 1798), an agricultural society, a philomathic, a Linnæan, a horticultural, and an archæological society; and maintains nine daily papers, about as many weeklies, and two or three monthly periodicals, besides the official publications of several of the above-mentioned societies. Its communal library, which dates from 1566, contains about 200,000 volumes; and it has also an antiquarian museum, a museum of natural history, and a picture gallery. Among its benevolent institutions are the hospital of Saint André, founded in 1825 to replace an older building of the same name, which dated from 1390, a children's hospital, originated in 1619, a hospital for incurables, a maternity and a military hospital, the lock hospital of Saint Jean, and a magnificent deaf and dumb asylum. Of theatres there are five,—the Grand Théâtre, finished in 1780 and seated for 1300; the Théâtre Louit, opened in 1868, for 2500; the Théâtre Français, dating from 1857, for 1300; the Théâtre National, opened in 1866, for 1000; and the Théâtre des Folies Bordelaises built in 1872. A few buildings are of merely antiquarian interest, the most important being the Palais Gallien, which is really an old Roman amphitheatre of the 3d century, and the tower of Pey Berland. Bordeaux is the seat of an archbishop, and has a court of appeal, a court of assize, and tribunals of primary instance and commerce. It has also a mint, the coinage of which is marked by the letter K. Its commercial institutions are necessarily numerous and varied; comprising an exchange, banks, insurance-offices, custom-

houses, public warehouses, and consulships of some forty different countries. The trade is very extensive, particularly in wines, and has undergone a remarkable development since the introduction of railways and steamships. For a long time Bordeaux was greatly indebted to the Languedoc canal, but this means of communication is now of minor importance. The total value of the export and import trade is annually about £16,500,000, about a third belonging to Britain. In 1872 the value of Bordeaux wines exported from France was upwards of £5,600,000, and the brandy and liqueurs from Bordeaux itself annually produce about £1,000,000. The other articles exported

comprise corn, fruits, sugar, wood, resin, rags, madder, tartar, gums, indigo, and native manufactures. Shipbuilding is a leading industry, the number of firms in that department being about twenty in 1875. In the same year 220 vessels belonged to the port, with a total tonnage of upwards of 92,000 English tons.

Bordeaux, or *Burdigala*, was originally the chief town of the Bituriges Vivisci. Under the Roman empire it became a flourishing commercial city, and in the 3d century it was made the capital of Aquitania Secunda. Ausonius, a writer of the 4th century, who was a native of the place, describes it as four-square and surrounded with walls and lofty towers, and celebrates its importance as one of the greatest educational centres of Gaul. In the evils that resulted from the disintegration of the empire Bordeaux had its full share, and did not recover its prosperity till the beginning of the 10th century. Along with Guienne it belonged to the English kings for nearly three hundred years (1154–1452), and was for a time the seat of the brilliant court of the Black Prince, whose son Richard was born in the city. An extensive commerce was gradually developed between the Bordeaux merchants and their fellow-subjects in England,—London, Hull, Exeter, Dartmouth, Bristol, and Chester being the principal ports with which they traded. For full details regarding the character of the traffic and its influence on the destinies of the city the reader may consult Francisque Michel's *Histoire du Commerce et de la Navigation de Bordeaux*, 1867. In 1548 the inhabitants resisted the imposition of the salt-tax by force of arms, a pardonable rebellion for which they were punished by Montmorency with merciless severity. At a later period they held out for the Frondeurs against the royal army under Louis XIV. and Richelieu, with an obstinacy that brought the monarch and his minister to a humbler mood. During the Reign of Terror the city suffered almost as severely as Lyons and Marseilles, and its commerce was greatly reduced under Napoleon I. In 1814 it declared for the House of Bourbon; and Louis XVIII. afterwards gave the title of duke of Bordeaux to his grandnephew, better known as the Count de

Chambord. In 1870 the French Government was transferred to Bordeaux from Tours on the approach of the Germans to the latter city. Population in 1872, 190,682.

Dupré de Saint Maur, *Hist. Curieuse de Bordeaux*, 1760; Devienne, *Hist. de la ville de Bordeaux*, 1771 and 1862; Bernadau, *Hist. de Bordeaux*, 1838–40; O'Reilly, *Hist. complète de Bordeaux*, 1853–60.

BOREAS, in Greek Mythology, was a personification of the north wind, and to be like it he was represented as rough, powerful, and accustomed to gain his ends by irresistible force. A favourite instance of this was the story of his carrying off the beautiful Oreithyia, a daughter of Erechtheus, king of Athens, when he found her gathering flowers by the banks of the Ilissus, or at the sources of the Cephisus,—others said the Areopagus, and others, again, the Citadel. He had sought before to woo her in vain, and now carried her to Mount Hæmus in Thrace, where they lived as king and queen of the winds, and had two sons, Zetes and Calaïs, and two daughters, Cleopatra and Chione. For the loss of Oreithyia the Athenians in after times counted on Boreas's friendliness, and were assured of it when he sent storms which wrecked the Persian fleet at Athos and at Sepias. For this they erected to him a sanctuary, or, as others said, an altar near the Ilissus, and held a festival in his honour. Thurii also, which was a colony of Athens, offered a sacrifice to him every year, because he had destroyed the hostile fleet of Dionysius the elder. Boreas was described as a son of Astræus and Aurora. In works of art he was represented as bearded, powerful, draped against cold, and winged. On the Tower of the Winds at Athens he is figured holding a shell, such as is blown by Tritons. Boreas carrying off Oreithyia is the subject of a beautiful bronze relief in the British Museum, found in the island of Calymna. The same subject occurs frequently on the painted Greek vases.

BORELLI, GIOVANNI ALFONSO, the head of what has been called the iatro-mathematical sect, or that which, misled by the great progress which the application of mathematics had produced in the physical sciences, attempted to secure the same advantage for medicine, by subjecting to calculation the phenomena of the living economy. He was born at Naples, January 28, 1608, taught mathematics for some time at Pisa, and seems afterwards to have held the professorship of medicine at Florence. He was greatly favoured by the princes of the house of Medici; but having been engaged in the revolt of Messina, he was obliged to retire to Rome, where he spent the remainder of his life under the protection of Christina, queen of Sweden, who honoured him with her friendship, and by her liberality softened the rigour of his fortune. He died of pleurisy on the 31st December 1679. Borelli, more judicious than Bellini, restricted the application of his system chiefly to muscular motions, or to those phenomena of the animal economy which are in certain points subject to the laws of mechanics, and was led to the discovery of some principles new in themselves, and directly opposed to the received beliefs of his time. His followers, less cautious, wishing to generalize the application he had made, by hypotheses, to which the return to a sound medical philosophy has done justice, greatly retarded the restoration of the science.

The works of Borelli are,—1. *Della Causa delle Febri maligni*, Pisa, 1658, 4to; 2. *De Renum usu Judicium*, Strasburg, 1664, 8vo; 3. *Euclides Restitutus*, 1628, 4to; 4. *Apollonii Pergæi Conicorum libri* v. vi. *et* vii., Florence, 1661; 5. *Theoriæ Medicæorum Planetarum ex Causis Physicis deductæ*, Florence, 1666, 4to; 6. *Tractatus de Vi Percussionis*, Bologna, 1667, 4to; 7. *Historia et Meteorologia incendii Æthnei*, Reggio, 1669, 4to; 8. *De Motionibus naturalibus a gravitate pendentibus*, Bologna, 1670, 4to; and 9. *De Motu Animalium, opus posthumum*, Rome, 1680, 1681, 4to.

BORGA, or BORGO, a seaport town of the Russian Grand Duchy of Finland, situated in the province of Nyland, at the entrance of the River Borga into the Gulf of Finland, about 25 miles N.W. of Helsingfors, in 60° 22′ N. lat. and 25° 45′ E. long. It was at one time a wealthy and handsome city, but has greatly decayed. It is still the seat of a Lutheran bishopric which extends over a large part of Finland; and it possesses a beautiful cathedral, a gymnasium (where the well-known Swedish poet Runeberg lectured for many years), and a theatre. The weaving of sail-cloth and the manufacture of tobacco are the principal industries, and the chief articles of trade are wood, butter, and meal. In 1873 the value of the imports, mainly from Germany, England, and Russia, was upwards of £141,000, while that of the exports was rather under £50,000. Borga was the seat of the Finnish diet in 1809. Population, which is mostly Swedish, in 1867, 3420.

BORGERHOUT, a flourishing township of Belgium, in the arrondissement of Antwerp, and on the road from that city to Turnhout. It has bleachfields, dye-works, woollen factories, and corn-mills. Population, 10,787.

BORGHESE, a noble Sienese family, one of whom, on being elected pope in 1605, assumed the name of Paul V., after which the family became among the most powerful of the Roman nobility by their union with the Aldobrandini. Camillo Filippo Ludovico, Prince Borghese (born 1775), married in 1803 Pauline, sister of the Emperor Napoleon, and widow of General Leclerc. In 1806 he was made duke of Guastalla, and for some years acted as governor of the Piedmontese and Genoese provinces. After the fall of Napoleon he fixed his residence at Florence, where he died in 1832. The Borghese palace at Rome is one of the most magnificent buildings in the city, and contains a splendid gallery of pictures.

BORGIA, CÆSAR and LUCRETIA. The history of Cæsar and Lucretia Borgia up to the death of their father has been related under ALEXANDER VI. (vol. i. p. 487). Alexander's sudden decease at an unfavourable conjuncture proved the ruin of Cæsar, who, as he subsequently told Machiavelli, had provided for every contingency except that of his father and himself being disabled at the same time. Though suffering from a dangerous illness, popularly believed to be the effect of poison, he possessed himself of his father's treasures, and exerted sufficient influence in the conclave to procure the election of a friendly pope. The pontificate of Pius III., however, only endured for a few weeks, and his successor, Julius II., the hereditary enemy of the Borgias, threw Cæsar into the prison of St Angelo, where he was detained until he had consented to deliver up all his fortresses. He was then sent to Naples, where the Spanish viceroy, Gonsalvo de Cordova, in violation of his pledge, caused him to be arrested and sent to Spain. After two years' confinement in the castle of Medina del Campo, he escaped and took refuge with his brother-in-law, the king of Navarre, in whose service he was slain before Viana, March 12, 1507. Cæsar possessed considerable abilities, but these are in general much overrated by historians, especially by Lord Macaulay in his essay on Machiavelli. His extraordinary success was not so much owing to the superiority of his qualities as to his utter emancipation from every restraint of conscience and honour. As a ruler he was intelligent and sagacious; his subjects regretted him, and his mercenaries served him with remarkable fidelity. Lucretia Borgia's life, after her marriage to the duke of Ferrara's son, was prosperous and uneventful, or at most only troubled by the not very well attested homage of Cardinal Bembo. She obtained universal respect by her piety and prudence, and her patronage of men of letters, and died in 1520. In fact, although intelligent and highly educated she was essentially a common-place woman, incapable from every point of view of the atrocities imputed to her by libellers in her own

day, and by poets and romancers ever since. She has suffered vicariously for her father and brother. See especially her latest historian, Gregorovius (*Lucrezia Borgia*, 1874), whose volumes contain a mass of most interesting information, especially relating to Lucretia's early years, but whose vindication of his heroine might have been much more decided. The English biography by Gilbert is well intended, but devoid of literary or historical value. (R. G.)

BORGO SAN DONNINO, a walled town of Italy, in the province of Parma, and capital of a circondario, is situated on the Stirone, a sub-tributary of the Po, about 15 miles W. of Parma on the railway to Milan. Besides its cathedral, a building of the 13th century, in the Lombard style, adorned with rude sculptures, it possesses a castle and fort, a theological seminary, a college, a music school, and a remarkable institution for mendicants. The spinning of hemp and silk and the manufacture of glass are its principal industries. Borgo is identified with *Fidentia*, memorable in ancient history for the siege sustained by M. Lucullus, one of Sulla's generals, against the forces of Carbo. It is mentioned as a *municipium* by Pliny, but seems afterwards to have sunk to a mere village. In 304 it was the scene of the martyrdom of Saint Domninus, from whom it has derived the distinctive part of its modern name. During the Hohenstauffen dynasty it was an imperial possession, and in 1501 it became the seat of a bishop. Population, 10,855.

BORGOGNONE, AMBROGIO. See FOSSANO.

BORGU, or BARBA, a large district in the interior of Africa, bounded on the E. by the Niger, on the S. by Yoruba, on the W. by Dahomey, and on the N. by Gurma. It is about thirty days' journey in length and eleven in breadth. It has generally a level surface, though crossed by a considerable range of mountains. The soil is mostly fertile, and tolerably cultivated, producing in abundance corn, yams, plantains, and limes. The cattle are numerous and of excellent breed, and there is a copious supply of all the species of game that prevail in Africa. A considerable inland trade between Haussa and the coast passes through this territory. When Clapperton entered it from Eyeo, he was warned to be on his guard, as the people were the greatest robbers and plunderers in all Africa, but he found this bad report altogether unjust. The people were honest, cheerful, obliging, good-humoured, and communicative. The district of Borgu is divided into a number of states, of which the smaller, such as Boussa, Wawa, Kiama, and Lugu, are dependent on the Fellatah kingdom of Gondo, while Kiti is ruled by a powerful and independent chief, who is frequently spoken of as sultan of Borgu. Wawa and Kiama are important commercial cities. Boussa was the scene of the disastrous fate of Mungo Park in 1805.

BORING. The methods and apparatus of boring will be found noticed under the different industries in which it is employed. See ARTESIAN WELLS, BLASTING, COAL, GUNS, &c.

BORISSOGLIEBSK, a town of Russia, in the government of Tamboff, 11½ miles S.E. of that city, in 51° 22′ N. lat. and 41° 4′ E. long., on the left bank of the River Vorona. It was founded in 1646 to defend the southern frontiers from the incursions of the Crim Tatars, and in 1696 was surrounded by wooden fortifications by command of Peter I. The public buildings include four churches, a hospital, and two schools; the principal industries are the preparation of wool, the manufacture of cast-iron, soap-boiling, tallow-melting, and brick-making; and the trade, which is decidedly important, consists in grain, wool, cattle, and leather. There are two annual fairs, and markets twice a week. Population in 1867, 12,254.

BÖRKU, or BORGU, a country in the interior of Africa, situated between the 17th and 20th parallels of N. lat., and between 18° and 21° E. long., and forming part of the great Soudan region. It is bounded northwards by the Tibesti Mountains, and is in great measure occupied by lesser elevations belonging to the same system; to the south or rather south-west lies the Bodele basin, from which it is separated by a narrow stretch of higher ground. The climate is much better than that of the neighbouring countries to the south and east; but the eastern trade-winds blow persistently with great violence, being strongest from early morning till about three P.M. The light sand that covers a large part of the country is drifted by it into countless heaps, that change their shape and position from day to day. It is plain, from the fish-skeletons still strewing the ground, that a considerable portion of the south of Borku has at no very distant day been like Bodele and other districts under water. At present the irrigated and fertile portions consist mainly of a number of valleys separated from each other by low and irregular limestone rocks. Of these the most important are Jin, Nguro, Elleboë, and Kirdi in the south, and Bodo, Tiggi, and Jarda in the north. They furnish excellent dates, of about twelve different sorts. The northern valleys and Jin are inhabited by a settled population of about 5000 people, known as the Donosa or Dosa; the others are mainly visited by nomadic tribes. The Uelad Sliman, a powerful Arab tribe, claim the lordship of the land, but have to share their authority with another tribe known as Mgharba which immigrated from Barca about 1860. They do not inhabit the country of Borku, but give proof of their claim to possession by plundering the valleys every three or four years. In the end of 1851 Dr Barth and Dr Oberweg joined an army despatched by the sultan of Bornu for the conquest of the region east of Lake Chad; but the army was defeated and put to flight, and the travellers were disappointed in their expectation of reaching Borku. Dr Nachtigal spent some time in the country in the year 1871, and gives an account of his sojourn in the *Zeitschrift der Gesellschaft für Erdkunde zu Berlin*, 1873.

BORLASE, WILLIAM, a learned antiquary and naturalist, was born at Pendeen in Cornwall, of an ancient family, February 2, 1696. He was educated at Exeter College, Oxford, where he took his degree as master of arts. In 1720 he was ordained as priest; he was instituted in 1722 to the rectory of Ludgvan, and in 1732 was presented to the vicarage of St Just, his native parish. In the parish of Ludgvan are rich copper works, abounding with mineral and metallic fossils, of which he made a collection, and thus was led to study somewhat minutely the natural history of the county. In 1750 he was admitted a fellow of the Royal Society; and in 1753 he published, in folio, at Oxford, his *Antiquities of Cornwall*, a second edition of which was published at London, 1769, with the title of *Antiquities, Historical and Monumental, of the County of Cornwall; consisting of several Essays on the Ancient Inhabitants, Druid Superstition, Customs, and Remains of the most remote Antiquity in Britain and the British Isles, exemplified and proved by Monuments now extant in Cornwall and the Scilly Islands; with a Vocabulary of the Cornu-British Language.* His next publication was *Observations on the Ancient and Present State of the Islands of Scilly, and their importance to the trade of Great Britain*, Oxford, 1756, 4to, which had previously been printed in the *Phil. Trans.* In 1758 appeared his *Natural History of Cornwall*, Oxford, folio. He presented to the Ashmolean Museum a variety of fossils and antiquities, which he had described in his works, and for his benefactions received the thanks of the university, and the degree of LL.D. He died August 31, 1772. Borlase was well acquainted with

most of the leading literary men of the time, more particularly with Pope, with whom he kept up a long correspondence, and for whose grotto at Twickenham he furnished the greater proportion of the fossils and minerals. His letters to Pope, St Aubyn, and others, with answers, fill several volumes of MS. There are also MS. notes on Cornwall, and a complete unpublished treatise *Concerning the Creation and Deluge.* Some account of these MSS., with extracts from them, will be found in the *Quarterly Review*, October, 1875. Borlase's memoirs of his own life were published in Nichol's *Literary Anecdotes*, vol. v.

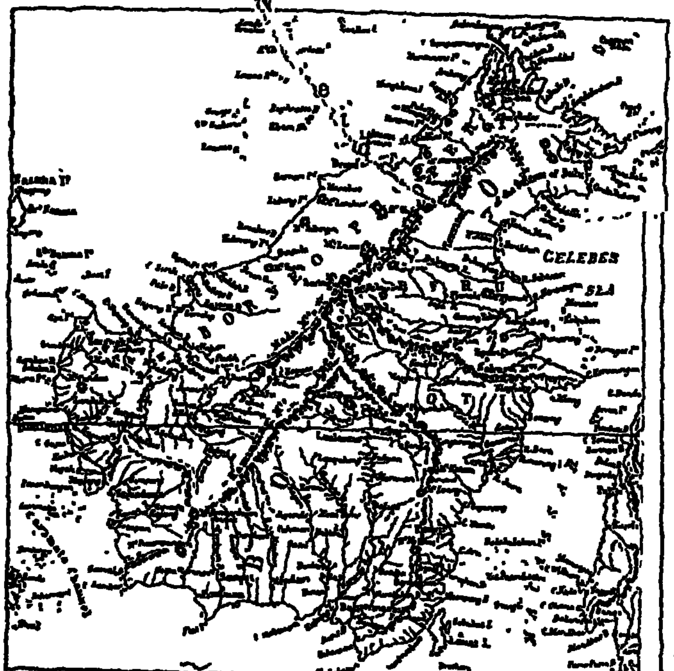
BORN, Ignatius, Baron von, an eminent mineralogist and metallurgist, was born of a noble family, at Karlsburg in Transylvania, in 1742 He was educated in a Jesuit college at Vienna, and entered that order, which, however, after sixteen months, he quitted. After studying law at Prague he travelled into Germany, Holland, and France. On his return to Prague he engaged in the study of mineralogy. Austria produces various metals in considerable abundance, and the administration of the revenue arising to Government from this source is conducted by local boards, under the control of the chamber of mines at Vienna. This administration offers a field of some preferment; and Von Born was received into the department of the mines and mint at Prague in 1770. About this time he met with an accident which nearly proved fatal, in the course of a journey through Transylvania. Having entered a mine at Felso-Banya, whilst the air was charged with arsenical vapour, he was stupified for fifteen hours, and long afterwards suffered from a cough and general pain. Some time after this accident he was affected with violent colics, and in the latter part of his life was deprived of the use of both legs. These calamities, however, did not repress the activity of his mind. He had to give up his assessorship of the mining council, but continued to produce works on mineralogy which won him a European reputation. He met with much opposition in attempting to introduce amalgamation in Hungary, in place of smelting and cupellation, for extracting silver from the ores. His opponents endeavoured to prove his process inferior to that already in use; and, after it had been tried successfully, pronounced it to be merely the old Spanish process of amalgamation. The emperor, however, ordered that his method should be employed in mines belonging to Government, and that he should receive a third part of the savings arising from the improvement during the first ten years, and 4 per cent. of this third part for the next twenty years. In 1766 he was appointed by Maria Theresa to arrange the imperial museum at Vienna, where he was made councillor of state, and continued to reside until his death. Von Born attempted satire with no great success. The *Staats Perucke*, a tale published without his knowledge in 1772, and an attack on Father Hell, the Jesuit, and king's astronomer at Vienna, are two of his satirical works. Part of a satire, entitled *Monachologia*, in which the monks are described in the technical language of natural history, is also ascribed to him. Von Born was well acquainted with Latin and the principal modern languages of Europe, and with many branches of science not immediately connected with metallurgy and mineralogy. He took an active part in the political changes in Hungary. After the death of Joseph, the diet of the states of Hungary rescinded many innovations of that scheming ruler, and conferred the rights of denizen on several persons who had been favourable to the cause of the Hungarians, and, amongst others, on Von Born. At the time of his death in 1791, he was employed in writing a work entitled *Fasti Leopoldini*, probably relating to the prudent conduct of Leopold II., the successor of Joseph, towards the Hungarians.

BÖRNE, Ludwig, German political writer and satirist, of Jewish family, was born 18th May 1786, at Frankfurt-on-the-Main, where his father, Jakob Baruch, carried on the business of a banker. He studied first at Berlin, where he became acquainted with Schleiermacher and the famous Henrietta Herz, and afterwards at Halle, intending to enter the medical profession. His inclinations for pure literature proved too powerful to allow him to carry out this design, and in 1806 he removed to Heidelberg in order to study financial and political economy. Two years later he took his degree at Giessen, and in 1811 he received an appointment in the bureau of police in his native town. The reconstitution of Frankfurt as a free city after the fall of Napoleon's power in Germany soon deprived him of a situation which was but little suited to his tastes or abilities. He then devoted himself to literature, and for a time edited a newspaper entitled *Staats-Ristretto*, which was quickly suppressed by the Government on account of its liberal tone and the boldness of its criticisms. The same fate attended his next venture, *Die Zeitschwingen*, which appeared for only four months. In 1817 he renounced his Jewish faith and took the name of Börne, by which he is always known. From 1818 to 1821 he edited *Die Wage*, a paper particularly distinguished by its lively political articles, and by its powerful but sarcastic theatrical criticisms. For some years after the suppression of his paper, Börne resided principally in Paris, Hamburg, and Frankfurt. After the July revolution (1830) he hurried to Paris, expecting to find the newly constituted state of society somewhat in accordance with his own philosophic views; but in this hope he was completely disappointed, and the bitterness of his anger lent additional force to the satirical letters he began to publish in his last literary venture, *La Balance.* While advocating his favourite scheme of a closer union between France and Germany, he assailed with unsparing sarcasm and polished wit the German dynasties, whom he looked upon as the great opponents of liberalism. He died at Paris in 1837. Börne's works are remarkable for brilliancy of style and for a thoroughly French vein of satire. His most elevated piece of criticism is the *Denkrede auf Jean Paul*, in which he shows himself fully able to appreciate the great German humourist. The *Menzel der Franzosenfresser* may be taken as a specimen of his unrivalled powers of sarcasm. There have been several complete editions of his writings, the latest being that of 1862, 12 vols., Leipsic; his life has been written by Gutzkow, 1840.

BORNEO, one of the largest islands of the world, is situated about the middle of the East Indian Archipelago, and lies immediately under the equator, between 7° N. and 4° 20' S. lat., and between 109° and 118° E. long. It forms a kind of irregular hexagon, and its area is estimated by Engelhardt at 289,000 Eng. square miles (more than double the area of the United Kingdom). Its coast-line is much less broken than that of most of the neighbouring islands; and though there are some extensive bays, such as Maludu in the north and Sarawak in the west, none of them are so deep as greatly to interfere with the regularity of its contour. A large proportion of the seaboard is of alluvial formation; and in various districts the deposition of new land is very perceptibly going on. The whole of the ground, for example, to the west of the Kandang Mountains in the kingdom of Landak has been gained from the sea during the last four centuries, and it is evident that many smaller islands which fringed the coast in former times have been incorporated with the mainland. This process of extension goes on all the more rapidly, because the neighbouring sea is very shallow, except on the eastern side.

Of the interior of the island a considerable part has been only partially explored, so that the physical features can

hardly be given with sufficient precision and detail. The general character of the country is mountainous, though none of the ranges and few of the individual peaks attain to any greatest elevation. The centre of the island seems to be occupied by a kind of table-land, with which the principal chains connect themselves more or less directly. Of these the most extensive may be traced from Cape Datu, on the west coast, in 2° 5′ 24″ N. lat., northwards through the length of the island, which it divides as water-



Sketch-Map of Borneo.

shed into two portions, a north-western of comparatively narrow dimensions, and a south-eastern comprising the rest of the island. The different parts of the chain are known by various local names, as the Krimbang or Bayang-Mint, the Batang-Lupar, the Madi, and the Anga-Anga Mountains. In the north-west corner of the island it attains its highest elevation in Kini-balu, or St Pietersberg, which is generally supposed to be the highest peak in the whole island. According to the trigonometrical measurement of Capt. Belcher the summit is 13,698 feet above the level of the sea, but this was in 1851 reduced to 9500 by Messrs Low and St John, who were the first to ascend the mountain. A second great chain, known as the Kaminting Mountains, stretches south-west from the Anga-Anga, and fills the south-west corner of the island with numerous offshoots and underfalls; and a third starting from the same quarter strikes first south-east and then south along the southern part of the eastern coast, and is known as the Meratu Mountains. A fourth chain, of which the most important part bears the name of Sakuru, runs almost due east to Cape Kamiungun.

Unlike the most of the larger islands of the archipelago, and in remarkable contrast with Java, Borneo seems to possess no active volcanoes. Many of the peaks, however, bear distinct evidence of former activity in regular craters, now in some cases forming lakes of salt water. The prevailing rocks are limestone, slate, sandstones, conglomerates, and on the mountain tops syenitic granite. The limestone hills are remarkable for the number of their caves, many of which, such as those of Rumbary, are a source of wealth to the natives, as they afford shelter to swallows that build edible nests.

Rivers. The island, which is abundantly supplied with rivers and streams, may be hydrographically divided into five principal versants. Of these the shortest lies along the north-western slope of the Krimbang and Kini-balu range, and discharges its waters into the Chinese Sea. The most important of its rivers are the Sarawak, the Batang-Lupar, the Seribas, the Rejang (which is navigable for 140 miles), the Baram (about half a mile wide at its mouth), the Limbang or Bruni River, the Tewaran, the Bintulu, and the Tampasuk, the last two having their sources in Mount Kini-balu itself. In the south-western versant the largest river is the Kapuas, which, rising towards the centre of the island, in about 114° E. long., falls, after a long and winding course, into the sea between Mempawa and Sukkadana. It has eight navigable mouths, and at Sintang, where it receives the Melawi, its principal tributary, it has a breadth of 1072 feet and a varying depth of 6 to 11 fathoms. The Banjermassin or Barito, which is the master stream of the southern versant, rises in the Kuti-Lama Lake, and reaches the Sea of Java in 114° 30′ E. long. Its upper channel is greatly interrupted by rocks and waterfalls, but the lower part of its course is wide and navigable, and traverses a rich alluvial district. Cross branches unite it with two rivers of considerable size towards the west, the Little Dayak or Murung and the Great Dayak or Kahayan, and still further west are the independent rivers Mendawi, Sampit, Pembuang or Surian, and Kota-Waringin. Passing over the south-east corner of the island, which is watered by a large number of short mountain streams, we reach the one great river of the eastern versant, the Kuti (Coti) or Mahakkan, which, rising in Mount Lassan-Tula, flows east, with a rapid and sinuous course, and falls by numerous mouths into the Strait of Macassar. Most of the rivers of the northern versant are comparatively small, as the island narrows into a kind of promontory. Besides the Sebuku, which rises in Mount Pentyieangan and falls into the sea at Temelingan, the Berou, the Gunong-Tebur, and the Bulungan are all worthy of mention.

Lakes. Among the lakes of Borneo that of Kini-balu, near the mountain of the same name, is regarded as the largest, but many others are of considerable size. The Danau Sriang, for example, on the Kapuas River, is, according to Dr E. van Martens, larger than the Lake of Constance. In the valley of the Banjermassin are the Babi and the Pamingir (or Telaga) lakes, the latter of which supplies nearly all the inhabitants of the kingdom with fish; and in the district of Sintang there is an extensive sheet of water, on the Kapuas-Tawang, which was discovered in 1825, and is known by the various names of the Luar, Sumbah, Malayu, or van Capellan Lake.

In spite of the equatorial position of the island its climate is nowhere oppressive, and in many places might almost be called temperate. At Pontianak, for example, which is almost under the equator, the mean reading of the thermometer is 82°, while it varies from 76° to 79° at sunrise, and hardly ever, even at noon, exceeds 92°. The difference between the rainy season and the dry is not rigidly marked; the atmosphere is moist all the year round, and while, on the one hand, there is hardly a day of continuous downpour, there is hardly, on the other hand, a day without a shower. During the rainy season, which extends from November to May inclusive, the torrents, while they last, are tremendous, and the wind is frequently violent. Over such an extensive area there is, of course, great variety in the climatic character of different districts, especially when viewed in relation to health. Some places, as Bidi, for example, are notoriously unhealthy; but from the statistics of the Dutch Government it appears that the European has in general no more to fear in Borneo than in the island of Java. Among the native races the prevailing diseases are principally those that arise from bad food or want of cleanliness. Scrofula is common throughout the

country, and elephantiasis is frequently met with on the coast. Small-pox, dysentery, and fevers are the usual epidemics; and ophthalmia sometimes attacks whole tribes. About a sixth of the native population in some quarters suffer from a kind of ringworm, called kurab, which is identified with *herpes farinosus.* Consumption is not uncommon.

The mineral wealth of Borneo is great and varied, including diamonds, gold, platina, quicksilver, cinnabar, copper, iron, tin, antimony, petroleum, sulphur, rock-salt, marble, and coal. Landak and Pontianak are the best diamond districts, and Sambas, Landak, Montrado, and Borneo Proper furnish the greatest quantity of gold. The annual amount of gold collected in the island cannot be ascertained; but the amount exported from Bruni in 1870 was 5789 dollars. Coal of excellent quality is found in the valleys of the Banjermassin, the Kuti, the Gunong-Tebur, and the Melawi, as well as in Sarawak, and in the island of Labuan. The Kuti deposit was discovered in 1845 or 1846 above Samarinda, and has since been struck in a number of places along the main river and several of the tributaries. A mine was opened at Pelarang, but does not seem to be at present worked. Another, however, at Pengaron, on the Riam Kiva, yields annually about 9000 or 10,000 tons. The coal-fields in Borneo Proper were conceded to Sir James Brooke in 1846, and since 1868 have been in the hands of the Oriental Coal Company, which has as yet taken no advantage of its rights. Antimony was discovered to be a Bornean product by Mr J. Craufurd, the well-known geographer, who, in 1825, learned that a quantity had been brought to Singapore by a native trader as ballast. The supply is practically unlimited, and the chief mine is at Bidi in Sarawak.

The fauna of Borneo comprises a large variety of species, many of which are numerically of great importance. Among the Quadrumana, which are very well represented, the most remarkable is the orang-outan (or *mias*, as it is called by the natives), an animal only to be found elsewhere in the Island of Sumatra. It frequents the low-lying districts, especially in the neighbourhood of the Dyak plantations. The wawah, a kind of gibbon, several *Semnopitheci* (as the longnosed ape and the golden-black or chrysomelas), and the large-eyed *Stenops tardigradus* are also worthy of mention. The larger beasts of prey seem to be altogether wanting, so that little check is put on the natural fecundity of the graminivorous species. A small panther and the *Felis macrocelis* are the largest animals of the cat-kind known; for though the tiger has sometimes been reported to occur in the mountains, its presence has never been verified. The Malay or honey bear is very common. The rhinoceros is found on the north-west coast, and the elephant, introduced by the Chinese or Portuguese, in the neighbourhood of Cape Unsang. Wild oxen of the Sunda race are not uncommon; and the whole island swarms with droves of wild pigs, which are distinguished by a curious protuberance of hair on each side of the head. These furnish food not only to the Dyaks, who are very fond of the flesh, but also to the crocodiles that abound in the principal rivers. Three or four species of deer are enumerated, one of which, the pelandok of the Malays, is remarkable for its smallness and beauty. Squirrels, porcupines, civet-cats, rats, bats, and lizards are well represented, and snakes of various kinds, from the boa constrictor downwards, are abundant, while the marshy districts swarm with frogs and leeches. The latter attach themselves in a most troublesome manner to the passing traveller. A remarkable flying-frog was discovered by Mr Wallace. Birds are comparatively rare in many quarters; the most important being eagles, vultures, falcons, owls, horn-bills, cranes, pheasants,—notably the Argus-pheasant,—partridges, ravens, crows, parrots, woodpeckers, doves, and swallows. The *Cypselus esculentus*, or edible-nest swallow, is very common. Mosquitoes and sandflies are the chief insect pests, and in some districts are very troublesome. There is also a kind of ant called the *sumpit-api* or fire-ant, the sting of which is very painful. The lepidopterous insects are remarkable for their number, variety, beauty, and size. In one favourable situation Mr Wallace caught 120 different species of moths in one night. The Coleoptera are no less numerously represented, as, indeed, might be expected in so richly-wooded a region. The lakes and rivers, as well as the surrounding sea, abound with fish. Dr Bleeker in his "Bijdragen tot de Kennis der Ichthyologische Fauna van Borneo," in the *Natuurkundig Tijdschrift van Nederl. Ind.*, describes 176 species which he obtained during his residence in the island.

The domestic animals of Borneo are few both in number of species and for the most part in number of individuals. The character of the country has prevented the development of pastoral modes of life. In some districts, as in the neighbourhood of Ambong, there are bullocks of the Brahmin breed, about thirteen hands high; the buffalo is sometimes employed in agriculture; and sheep and goats occur. The cat and dog are both domesticated. A few horses, introduced by Europeans, and only possessed by the wealthier classes, are found in Banjermassin and Sarawak.

The flora of Borneo is very rich, the whole surface of Pl
the island being clothed in luxuriant vegetation. The king of the forest is the *tappan*, which, rising to a great height with a single branchless stem, is crowned with a splendid dome of foliage. From the wood of this tree the chiefs construct their official seats. The iron-wood, so remarkable for the durability of its timber, is abundant; it is used by the natives for the pillars of their houses, and forms an article of export to China. It is almost rivalled by the *kayu temesu* in hardness. In all about sixty kinds of timber are furnished in more or less profusion. Palm-trees are abundant in great variety, including the *nipa*, cabbage, fan, cocoa-nut, and sago palms; the two last afford large supplies of food to the natives. Gutta-percha, camphor, cinnamon, cloves, nutmegs, gambir, and betel-nuts are all produced in the island; most of the tropical fruits flourish, such as the mangosteen, the lansat, rambutan, jack, jambon, and blimbang; nor must the wonderful durian be forgotten, of which Mr Wallace enthusiastically declares that it is worth a voyage from Europe to taste it. It is a large fruit with an exceedingly strong spiked outer covering, and not unfrequently inflicts severe wounds by falling on the passers by. Yams, potatoes (an indigenous sort), melons, pumpkins, cucumbers, pine-apples, and bananas, sugar, pepper, cotton, and tobacco are cultivated, though not as yet on a very extensive scale. In the south-eastern division of the Dutch territory the export of cotton was in 1854 1795 picols. The product of the wild plant is very good, and is exported from Borneo Proper. Among the more beautiful of the flowering plants are rhododendrons, orchids, and pitcher-plants,—the last reaching a most extraordinary development, especially in the northern districts about Kinibalu. Epiphytous plants are very common, many that are usually independent assuming here the parasitic character. The *Vanda Lowii*, for example, "grows on the lower branches of trees, and its strange pendent flower-stalks often hang down so as almost to reach the ground." Ferns are abundant, but are not so varied as in Java; Mr Wallace collected fifty species.

The population of Borneo consists of a considerable Inhal
variety of races, of very different origin, and of different tants
degrees of civilization. The most important numerically are the Dyaks, the Malays, the Chinese, and the Bugineso:

and, from their political influence, the Arabs and the Dutch.

Dyaks. The Dyaks, Dayaks, or Dayakkers are generally regarded as the most aboriginal. For themselves they have no general designation; but, broken as they are into numerous tribes, they are distinguished by separate tribal names, many of which seem to be merely the names of the rivers on which their settlements are situated. Though regarded by the Malays as aliens, and looked down upon as almost beneath humanity, they belong to the same race. Separation, however, must have taken place at a very early date. Kessel, who has attempted to form a classification of the Dyaks according to their ethnographical affinity, divides them into five principal branches. The first of these, which he calls the north-western, includes the natives of Sadong, Sarawak, Sambas, Landak, Tayan, Melionow, and Sangow. They all speak the same language, and are remarkable for their dependence on the Malay princes. The second branch, which is called emphatically the Malayan from its greater retention of Malay characteristics, occupies the north coast in Banting, Batang-Lupar, Rejang, and part of the valley of the Kapuas. To the third or Parian branch belong the Dyaks of the rivers Kuti and Passir, who are said to speak a language like that of Macassar. The fourth consists of the Beyadjoes, who are settled in the valley of the Banjermassin; and the fifth and lowest comprises the Manketans and Punans, who are still nomadic and ignorant of agriculture. In stature the Dyak is rather above the Malay, while still considerably shorter than the average European. He is rather slightly built, but is active and capable of enduring great fatigue. His features are distinctly marked and often well-formed, though the cheekbones are higher and the nose more *retroussé* than agrees with the European standard. The forehead is generally high, and the eyes are dark; the hair is black, and the colour of the skin a pure reddish brown, that frequently, in the female, approaches to a Chinese complexion. In general neither beard nor whiskers are present, but this does not hold of all the tribes. In dress there is considerable variety, great alterations having resulted from foreign influence. The original and still prevailing style is very simple, consisting of a mere *chawat* or waistcloth, generally of blue cotton, for the men, and a tight-fitting petticoat for the women, who acquire a peculiar mincing gait from its interference with their walking. The favourite ornaments of both sexes are brass rings for the legs and arms, hoops of rattan decorated in various ways, necklaces of white and black beads, and crescent-shaped ear-rings of a large size. Tattooing is commonly practised by most of the tribes. The men usually go bare-headed, or wear a bright-coloured kerchief. The custom of betel-chewing being almost universal, the betel-pouch worn at the side is a necessary part of the equipment. The weapons in use are a *klewary* or curved sword and a long spear. The bow is unknown, but its place among some tribes is partly supplied by the *sumpitan*, or blowpipe, in the boring of which they show great skill. When going to war the Dyak invests himself with a strong padded jacket, which proves no bad defence. Not only is it a custom with many tribes to preserve the skulls of their slaughtered enemies as trophies of their success in war; but, as the possession of a certain number of human heads is necessary before a man can be admitted to some of the most important of his social privileges, it is usual for the young men to go out on private head-hunting excursions. The custom, however, is dying out before the influence of civilization.

The Dyak is decidedly intelligent; his memory is tenacious, and his powers of observation good. Unacquainted in his natural state with both reading and writing, his aptitude for acquiring these arts is greatly praised by missionaries. In moral character he is far superior to the civilized Malay, being unsuspicious and hospitable, and honest and truthful in a striking degree. The various tribes differ greatly in religious ceremonies and beliefs, and it is hard to give a satisfactory idea of them. They have no temples, priests, or regular recurrence of worship; but the father of each family performs such rites as the exigencies of each day demand. A supreme god seems generally acknowledged, but subordinate deities are supposed to watch over special departments of the world and human affairs. Sacrifices both of animals and fruits—and in some cases even of human beings—are offered to appease or invoke the gods; divination of various kinds is resorted to for the purpose of deciding the course to be pursued in any emergency; and criminals are subjected to the ordeal by poison or otherwise. There is a very strong belief in the existence of evil spirits, and all kinds of calamities and diseases are ascribed to their malignity. Thus almost the whole medical system of the Dyaks consists in the application of appropriate charms or the offering of conciliatory sacrifices. Many of those natives who have had much intercourse with the Malays have adopted a kind of mongrel Mahometanism, with a mixture of Hindu elements. The transmigration of souls seems to be believed in by some tribes; and some have a system of successive heavens rising one above the other very much in the style of the Hindu cosmogony. In the treatment of their dead the same variety prevails as in other things—they are sometimes buried, sometimes burned, and sometimes elevated on lofty framework. The Dyaks have no exact calculation of the year, and simply name the months first month, second month, and so on. They calculate the time of day by the height of the sun, and if asked how far distant a place is can only reply by showing how high the sun would be when you reached it if you set out in the morning. In agriculture, navigation, and manufactures they have made some progress. In a few districts a slight sort of plough is used, but the usual instrument of tillage is a kind of cleaver. Two crops, one of rice and the other of maize or vegetables, are taken, and then the ground is allowed to fallow for eight or ten years. They spin and weave their own cotton, and dye the cloth with indigo of their own growing. Their iron and steel instruments are excellent, the latter far surpassing European wares in strength and fineness of edge. Their houses are neatly built of bamboos, and raised on piles a considerable height from the ground; but perhaps their most remarkable constructive effort is the erection of suspension bridges and paths over rivers and along the front of precipices, in which they display a boldness and ingenuity that surprise the European traveller.

The Dyaks speak a variety of dialects, most of which are still very slightly known. The tribes on the coast have adopted a great number of pure Malay words into common use, and it is often hard to ascertain their own proper synonyms. The American missionaries have investigated the dialects of the west coast (Landak, &c.), and their Rhenish brethren have devoted their attention to those of the south, into one of which (that of Pulu Petak) a complete translation of the Bible has been made. Mr Hardeland, the translator, has also published a Dyak-German dictionary. (See Vocabularies in St John's *Life in the Forests.*) On the authority of the sultan of Bruni, who in 1824 visited Singapore, Crawfurd asserts that of the forty wild tribes that inhabit Bruni, eight had completely, and five partially, adopted the Malay speech. The dialect of the Kayans seems to be one of the purest,—nine-tenths of its words having no cognates in the other languages of the archipelago.

For an account of the Malays the reader must be referred to a separate article, but the Chinese require more particular notice. They seem to have been the Chinese inhabitants.

first civilized people who had dealings with Borneo: their own annals speak of tribute paid to the empire by Pha-la on the north-east coast of the island as early as the 7th century, and later documents mention a Chinese colonization in the 15th. The traditions of the Malays and Dyaks support these statements,—the people of Bruni regarding themselves as partly of Chinese descent, and the annals of Sulu recording an extensive Chinese immigration about 1575. Be this as it may, the flourishing condition of Borneo in the 16th and 17th centuries was largely due to trade with China. The Chinese founded in the 18th century an important colony in Bruni; but their numbers were lessened by the bad treatment of the princes. The Malay chiefs of other districts invited them to come and develop the mineral wealth of the country, and before long they were to be found in considerable numbers in Sambas, Montrado, Pontianak, and elsewhere. They were at first forbidden to engage in commerce or agriculture, and prevented from wearing fire-arms or possessing gunpowder. About 1779 the Dutch acquired immediate authority over all strangers, and thus had the means of controlling the new colonists, who soon proved themselves rather troublesome. Their numbers continually increased, and they pushed inland to new mineral districts, forming friendships and contracting marriages with the Dyaks. For the better management of their affairs they entered into extensive associations, which gradually assumed more and more of a political character until they were almost regular confederacies. This rendered them at once more disposed and more able to assert their claims to independence; and it cost both the Dutch Government and the Rajah of Sarawak several severe contests to bring them to terms. They form at the same time one of the most valuable elements in Bornean civilization, and are an industrious, intelligent, and well-educated race. It would be hard to find a man among them who cannot read and write; and their first care in a new settlement is to found a school. The greater part of those on the west coast are emigrants, originally from the northern boundaries of Quang-tung and Quang-si. They are rough, stern, and quarrelsome. A more polished class come from the coast district of Amoy, and look down on their ruder fellow-countrymen, from whom they keep themselves markedly distinct. The former class are called Kehs by the Borneans, and the latter Ollohs.

ties pula- In regard to the number of the population of Borneo it is difficult to arrive at anything like a satisfactory estimate. The inland districts seem to be very thinly inhabited; and the Dyaks increase in numbers at a very slow rate, in spite of their being both a healthy and moral people. This is attributed by Mr Wallace mainly to infecundity on the part of the women brought on by the excessive labour to which they are subjected from early girlhood. The population of the Dutch territory was stated in 1871 at 335,677 natives and 131 Europeans in the western division, and at 847,846 natives and 320 Europeans in the south-eastern, making a total of 700,386; but the statements rest on little better than conjecture. If they approximate to the truth, the population of the whole island may be set down at between 1,000,000 and 2,000,000. Earlier estimates carried the total as high as 3,000,000.

torial ons. Borneo is politically divided into Borneo Proper or Bruni (inclusive of Sarawak), the territory of the sultan of Sulu, and the Dutch possessions and protectorate. Bruni is an ro er. independent country, governed by a sultan, who is nominally absolute; but the real power is distributed among the subordinate chiefs, who act each as much as possible as his own master. The inhabitants are all serfs of the sultan or the chiefs, who may dispose of their property, their wives, or their children in the most arbitrary manner. Mahometanism is the state religion. The capital, also called Bruni, is a large and flourishing city. The estimates of its population have all along greatly varied. Among the most recent is one which makes it 30,000 or 40,000, while the population of the whole kingdom is given at 225,000. A considerable traffic is carried on with Malacca, Singapore, China, Rio, Sambas, Pontianak, and other places in the Dutch possessions. There is an extensive fishing in the river, the produce of which furnishes the people with a large proportion of their food. The fishermen form a distinct caste, and the same is the case with the workers in brass, the blacksmiths, the goldsmiths, the matmakers, &c. The manufacture of goldlace and silk embroidery is carried to great perfection. For accounts of Sarawak and the Sulu territory the reader is referred to separate articles.

The Dutch territory forms two great divisions, the western and the south-eastern. The western, governed by a resident, is subdivided into two parts, Pontianak and Sambas, the former administered by the resident himself and the latter by an assistant-resident and the sultan of Sambas. Pontianak includes Landak, Tajan, Mampawa, Sintang, Selimbou, Upper-Kapuas, and Montrado, while to Sambas belong the districts of Pamangkut and Seminis. The south-eastern division is subdivided into an eastern and a southern part. Under the southern are Kota-Waringin, Pembuang, Sampitite, Great and Little Dyak, Bekompai, Duson, Banjermassin, and Tanah-Laut; and under the eastern are Tanah-Bumbu, Kusan, Passir, Kuti, Sambiliung, Gunong-Tebur, Bulungan (the three last being also known as Berou), and the Tidung lands. The east coast, from Sebamban in Tanah Bumbu to Kaniungan in 1° 3′ N. lat., belongs immediately to the Dutch Government. In the western division several important military roads have been constructed, and the resources of the country are being opened up. Dutch territory.

Borneo has never, as far as we have information, formed a political unity; and even its physical unity as an island is so little known or considered by its native inhabitants that it possesses in their languages no general designation. As a natural consequence Borneo has no proper history. The island was first discovered by European navigators in the beginning of the 16th century, according to one account by Lorenzo de Gomez, a Portuguese, in 1518, and according to another by Don Jorge de Menezes in 1526. Before long commercial relations were formed with the natives by the Portuguese traders, at first in the city of Bruni itself, and then in various other maritime states. In 1573 their Spanish rivals tried to open a connection with Bruni, but their attempts were without success till the sultan being dethroned appealed to them for assistance, and was restored in 1580. From that time they kept up intercourse with the country, but it was not unfrequently interrupted by war. In 1645 an expedition was sent to punish the inhabitants of the capital for their piratical excursions. The real influence exerted by the Portuguese and Spaniards on the condition of the country was very slight; and the only effort at proselytizing of which we have record came to an untimely end in the death of the Theatine monk, Antonio Ventimiglia, who had been its originator. Meanwhile the Dutch and English had been gaining a footing in the island. In 1604 Waerwijck began to trade on the west coast, and in 1608 Samuel Blommaert was appointed Dutch resident in Landak and Sukkedana. The English appeared for the first time about 1609, and by 1698 had an important settlement at Banjermassin, from which, however, they were expelled by the influence of the Dutch, who about 1733 obtained from the sultan a monopoly of the trade. The Dutch, in fact, became paramount all round the west and south coasts, and the king of Bantam ceded his rights History.

of suzerainty to the company. The attention of the English was meantime turned to the north of the island, which was subject to the sultan of Sulu, from whom, in 1756, Alexander Dalrymple obtained possession of the island of Balambangan, and all the north-eastern promontory. A military post was established, but in 1775 it was surprised and destroyed by the natives under the *dutus* or subordinate chiefs, who were dissatisfied with the cession of their territory. This disaster rendered a treaty, which had just been concluded (in 1774) with the sultan of Bruni, in great measure a dead letter, and before the end of the century English influence in Borneo was practically at an end. The Dutch, too, were overtaken, in spite of apparent success, with a succession of misfortunes, through their own mismanagement; and in 1809 their settlements were all abandoned by order of Marshal Daendels. The natives along the coast, assisted and stimulated by immigrants from the neighbouring islands to the north, gave themselves more and more to piracy, and rendered the trade of civilized nations almost an impossibility.

In 1811, however, an embassy was sent to the British Government in Java by the sultan of Banjermassin to crave their assistance, and in reply Alexander Hare was despatched as commissioner and resident. He not only formed an advantageous treaty with the sultan, but got for himself a grant of a district of country which he proceeded to colonize and cultivate. An expedition was also sent against Sambas, and a post established at Pontianak. On the restoration of the Dutch possessions in 1818 all these arrangements were cancelled, and a free field was left to the enterprise of the Dutch Government. A succession of active commissioners—Boekholtz, Tobias, Halewijn, &c.—soon laid the foundations of an extensive supremacy. About half of the kingdom of Banjermassin was surrendered by the sultan in 1823, and further concessions were granted by his son in 1825. Meanwhile, George Muller was exploring the east coast, and obtained from the sultan of Kuti an acknowledgment of the Dutch authority—a concession which seems to have been immediately regretted, as the enterprising traveller was shortly afterwards killed. The outbreak of a war in Java turned the attention of the Dutch in some measure from Borneo, and nothing was done by them to check the piracy which was growing more and more unendurable. On the rise of Singapore direct trade had been opened with Sarawak and Bruni, and it was a matter of moment to the English merchants that their traffic should be safe. In 1838 Sir James Brooke, an Englishman, whose attention had been turned to the state of affairs in the Eastern Archipelago, set out for Borneo, determined, if possible, to remedy the evil. By 1841 he had obtained from the sultan of Bruni the highest authority in Sarawak, and before many years were over he succeeded in restoring order and peace to the district, and, with the assistance of the English Government, in repressing piracy. (See BROOKE and SARAWAK.) In 1847 the sultan of Bruni agreed to make no cession of territory to any nation or individual without the consent of Her British Majesty. The Dutch hopes of gradually incorporating the whole island were thus frustrated, but this served only to increase their activity in other directions. In 1844 the sultan of Kuti had acknowledged their protectorate, and about the same time a treaty of similar character was formed with Passir. Since 1834, when Gunong-Tebur, Tanjong, and Bulungan are said to have made a nominal submission, the boundaries of their authority have undergone no change to the north; and in general their political power has been rather rising in level, so to speak, over the southern part of the island than seeking to spread over a wider area.

Of the works on Borneo, which are very numerous, the following may be named:— Blommaert's *Discours ende ghelegentheyt van het eylandt Borneo int Jaar 1609*; *Hachelyke reystogt van Jacob Janss. de Roy na Borneo en Atchin in het jaar 1691*; Beeckman, *Visit to Borneo*, 1718; Valentijn's description in his great work, 1726; *Berigt van een reiziger over Borneo Propre* in P. P. Roorda van Eysinga's *Verschill. reizen en lotgevallen*, vol. iv.; G. W. Earl, *Eastern Seas*, 1837; W. L. Ritter, *Indische Herinneringen*, &c., 1843; S. Muller, *Reizen in den Ind. Archip.*; Keppel, *Expedition of the Dido*, 1846; Mundy, *Narrative of events in Borneo and Celebes*, 1848; Belcher, *Voy. of the Samarang*, 1840; H. Low, *Sarawak*, 1848; F. S. Marryat, *Borneo, &c.*, 1848; Keppel, *Visit to Ind. Archipel. by the Mæander*, 1853; J. C. Temple, *Private Letters of Sir J. Brooke*, 1853; H. St John, *The Indian Archip.*, 1853; C. A. L. M. Schwaner, *Borneo, Beschr. van het stromgebied van den Barito, etc., in den jaaren 1843–47*, 1853–4; P. J. Veth, *Borneo's Westerafdeeling*, 1854, 1856 (a work which has been largely used in the preparation of the present article); E. Francis, *Herinneringen uit het leven van een Indisch. ambtenaar*, 1856; J. J. Rochussen, *Toelichting, etc. van eenige daden van mijn bestuur*, 1853; W. A. van Rees, *Montrado, &c.*, 1858; C. J. Temminck, *Coup d'œil sur les poss. Neerland. dans l'Inde Archipel.*, 1846–50; Ida Pfeiffer, *Zweite Weltreise*, 1856; MacDougall, *Letters from Sarawak, addressed to a Child*, 1854; Crawfurd, *Descriptive Dictionary*, art. *Borneo*; W. E. Kroesen and F. H. van Vlissingen, *Cultuur- en Industrie-ondernemingen van Borneo*, 1859; J. Hasselman and F. H. van Vlissingen, *Beschouwingen over de exploitatie van Borneo*, 1859; Tracy, *History of the American Board of Commissioners for Foreign Missions*, 1842; Spenser St John, *Life in the Forests of the Far East*, 1862; F. Boyle, *Adventures among the Dyaks of Borneo*, 1865; A. R. Wallace, *The Malay Archipel.*, 1869; P. J. Veth, *Woordenboek van Nederl. Indie*, 1869; (in this work the reader will find a long list of articles on Borneo that have appeared in Dutch and other periodicals); "Contribuzioni geografiche italiane a Borneo" in the *Cosmos* of Guido Cora, 1874. (H. A. W.)

BORNHOLM, an island in the Baltic, belonging to Denmark, in the "Stift" of Seeland, between 54° 59' and 55° 18' N. lat., and between 14° 42' and 15° 8' E. long. It is about 20 miles in length by 14 in breadth, with a generally mountainous surface and steep and rocky shores. Besides a good freestone, which is largely exported for building, it furnishes limestone, blue marble, coal, and clay. Oats, flax, and hemp are cultivated. The population amounts to about 33,000, and is chiefly employed in agriculture, fishing, brewing, distillation, and the manufacture of earthenware. Weaving and clock-making are also carried on to some extent. The capital is Rönne, and there are six other small towns on the island,—Svanike, Nexöe, Hasle, Allinge, and Sandvig,—the total town population amounting to 11,100. On the north-west coast are the ruins of the castle of Hammershuus, which was built in 1158, and long served as a state-prison; while another old castle, erected by Christian V. in 1684, and important as commanding the entrance to the Baltic, is situated on Christiansöe, one of a small group of islands about 11 miles to the north-east. The island of Bornholm has had a very eventful history. For a short time, in the 9th century, it formed a separate principality or kingdom, which was afterwards united to Denmark. In 1510 it was captured by the Hanseatic League, and in 1522 it became directly subject to the city of Lübeck. In 1645 the Swedes took it by storm, and their possession of it was confirmed by the peace of Roeskild in 1658; but the sympathies of the people were with Denmark, and a popular insurrection succeeded in expelling the Swedish forces.

BORNU, or BORNOU, a kingdom of Central Africa, situated to the south-west of Lake Chad, and separated from the Niger by the kingdom of Haussa. Its area is estimated at 51,250 square miles, and its population at 5,000,000. The country is for the most part a flat alluvial plain, subject in its north-eastern portions to inundation from the lake and its tributary rivers—the Shari and the Yo. The former of these, which is by far the larger, serves as a boundary towards Baghermi on the east; the latter, rising in Haussa, flows north-east through the whole country. The soil is in general fertile and well watered, yielding large crops even under very imperfect cultivation.

One of the finest districts in the country is that of Uje, which is inhabited by the Ghamergu tribe. The labour is chiefly performed by female slaves, who, besides their other labours are obliged to perform the perilous task of guarding the growing crops against animal depredators. The rice and wheat are excellent, but are grown in small quantity. The grain which forms the staple food of the people, is a species of millet called *gussub*, which they form, not into bread (an article here entirely unknown), but into a species of paste, which, by the addition of butter and honey, forms the highest boast of Bornu cookery. Cotton and indigo grow wild, and afford the materials for the cloths finely dyed with blue stripes, which form the staple fabric of the country. Onions and water-melons are almost the only vegetables, and besides tomatoes the only fruits are a few limes and figs. The prevailing bush is the *Asclepias gigantea*, and the woods consist largely of acacias and tamarinds. The caoutchouc tree is very common, but its juice has not as yet been utilized by the inhabitants. All the domestic animals are reared, and there are very numerous herds of oxen, possessed chiefly by the Shuwa tribe. Animal food is thus very cheap, and forms a large proportion of the ordinary diet.

Wild animals, in great numbers, find both food and cover in the extensive districts of wood and marsh. Lions, giraffes, elephants, hyenas, crocodiles, and hippopotami are common; and antelopes, gazelles, ostriches, and various other animals are pursued as game. The country abounds with bees; and the honey, though only partially collected, forms one of the chief Bornuese delicacies. The climate, especially from March to the end of June is oppressively hot, rising sometimes to 105° and 107°, and even during most of the night not falling much below 100°. In May the wet season commences, with violent storms of thunder and lightning. In the end of June the rivers and lakes begin to overflow, and for several months the rains, accompanied with sultry weather, are almost incessant. The inhabitants at this season are severely afflicted with fever and ague, which carry off great numbers. In October the rains abate; cool, fresh winds blow from the west and north-west; and for several months the climate is both healthful and agreeable.

The leading people of the country, called Bornuese or Kanuri, present a perfect specimen of the negro form and features; having large mouths, thick lips, and broad noses, but good teeth and high foreheads. The females add to their want of beauty by extensive tattooing; they also stain their faces with indigo, and dye their front teeth black and their canine teeth red. The law allows polygamy, but even the richest have seldom more than two or three wives. The marriage ceremonies last for a whole week, the first three days being spent in feasting on the favourite national dishes, and the others appropriated to certain symbolical rites. The favourite amusement is to watch the wrestling of slaves taken in war from the neighbouring nations. Another amusement is a rude game bearing some resemblance to chess, played with beans and holes in the sand. The Mahometan religion is universally professed in Bornu, and with bigotry and violence. The prevailing language of the people is known as the Kanuri. It has no affinity, according to Dr Barth, with the great Berber family. A grammar was published in 1854 by S. W. Koelle, as well as a volume of tales and fables, with a translation and vocabulary.

The pastoral districts of the country are occupied by the Shuwas, who are undoubtedly of Arabian race, and speak a well-preserved dialect of that language. Of the date of their immigration from the East we have no knowledge; but they were in the country as early as the middle of the 17th century. Their total number is from 200,000 to 250,000, and they are divided into numerous distinct clans. Their villages in general consist of rudely-constructed huts, of an exaggerated conical form. Another tribe, called the La Salas, inhabit a number of low fertile islands in Lake Chad, separated from the continent by channels which those who know the tracts can ford on horseback.

The military force of Bornu consists almost entirely in cavalry, amounting to about 30,000, who are mounted on heavy steeds, which, as well as their riders, are frequently cased in light iron mail. The Shuwas, however, are clad only in a light shirt, and mounted on small unseemly nags, and the Kanembu spearmen are almost naked, and fight with shield and spear. Camels and oxen are used for conveying the baggage. The sheikh of Bornu is surrounded by a mounted body-guard, who likewise compose his principal nobles and chiefs. It is indispensable to the chief of rank that he should possess a huge belly, and when high feeding cannot produce this, padding gives the appearance of it. Notwithstanding the heat of the climate, the body is enveloped in successive robes, the number indicating the rank of the wearer. The head likewise is enclosed in numerous turbans.

The towns are of considerable size. They are surrounded with walls 35 or 40 feet in height, and 20 feet in thickness, having at each of the four corners a triple gate, composed of strong planks of wood, with bars of iron. The abodes of the principal inhabitants form an enclosed square, in which are separate houses for each of the wives; the chief's palace consists of turrets connected together by terraces. These are well built of a reddish clay, highly polished, so as to resemble stucco; the interior roof, though composed only of branches, is tastefully constructed. Kuka (or Kukawa, as it is called from its consisting of two distinct parts) is situated near the western shore of the lake, and has a population of 60,000. Still more populous is Ngornu, Angornou, or Gornu (the town of the "Blessing"), which lies about 18 miles to the south-east. It carries on a large trade, and contains about 50,000 inhabitants. On the Waube or Yo are still to be seen extensive remains of Old Bornu or Birni and Gambarou or Ghambaru, which were destroyed by the Fulbe about 1809. Among the other towns of more or less importance are Alaw, where Edris Alawoma, the famous king of Bornu, is buried, Alamay, Allauna, or Kabshari, Borzani, Lamiso, Masheña, Uje Maidugari, Uje Maibani, Wushek, and Yo.

The history of Bornu goes back only to the 9th century of our era, and its early portions are very fragmentary and dubious. The first dynasty known is that of the Séfuwa or descendants of Sef, which came to the throne in the person of Dugu or Duku, and has its capital at Njimiye in Kanem. Mahometanism was adopted about 1086 by the ruling monarch, Dúnama Ben Humé, and has since continued the religion of the country. From 1194–1220 reigned Selma or Abd-el Jelil, under whom the power of the kingdom was greatly extended; and Dúnama, his successor, was also a powerful and warlike prince. In the following reigns the prosperity of the country began to diminish, and in 1386 the dynasty was expelled from Njimiye, and forced to seek refuge in the western part of its territory by the invasion of the Bulála. Mai Ali Ghajideni, who founded the city of Birni or Ghasrggomo, on the River Wau, rendered his country once more redoubtable and strong. His successor, Edris, completely vanquished the Bulála and subjugated Kanem; and under Mohomet, the next monarch, Bornu reached its highest pitch of greatness. A series of for the most part peaceful reigns succeeded till about the middle of the 18th century, when Ali Omarmi entered upon a violent struggle with the Tuaricks or Imoshagh. Under his son Ahmed (about 1808) the kingdom began to be harassed by the

Fulbe or Fellatah, who had already conquered the Haussa country. Expelled from his capital by the invaders, Ahmed was only restored by the assistance of the fakir Mahomet el-Amin el-Kanemi, a mere private individual, who, pretending to a celestial *mission*, hoisted the green flag of the prophet, and undertook the deliverance of his country. The Fellatahs appear to have been taken by surprise, and were in ten months driven completely out of Bornu. The conqueror, having the army wholly devoted to him, might probably have, with little difficulty, assumed the sovereign power. More moderate, and perhaps more prudent, he invested the nearest heir of the ancient kings with all the appearance and pomp of sovereignty,—only reserving for himself, under the title of sheikh, all its reality. The court of the king or sultan was established at New Bornu, or Birni, which was made the capital, the old city having been entirely destroyed during the Fellatah invasion; while the sheikh, in military state, took up his residence at the new city of Kuka. Fairly established he ruled the country with a rod of iron, and at the same time inspired his subjects with a superstitious notion of his sanctity His zeal was peculiarly directed against moral or religious offences. The most frivolous faults of females, as talking too loud, and walking in the street unveiled, rendered the offender liable to public indictment, while graver errors were visited with the most ignominious punishments, and often with death itself. Kanemi died in 1835, and was succeeded by his son, Sheikh Omar, who altogether abolished the nominal kingship of the Sefuwa. The intercourse of Europeans with Bornu has, during his reign, been for the most part satisfactory as well as frequent. The expectations entertained at various times of opening up a valuable commerce with the people have not been as yet realized, and it seems likely, from the latest reports, that before long the traveller in Central Africa will have little to hope or fear from the sheikh of Bornu. Dr Barth, who was at Kuka in 1851, foreboded this decay; and Dr Nachtigal, who in 1870 conveyed the friendly presents sent by King William of Prussia, in acknowledgment of the sheikh's kindness to so many German explorers, writes thus in December 1872 :—

"The rapid declension of Bornu is an undeniable and lamentable fact. It is taking place with increasing rapidity, and the boundless weakness of Sheikh Omar—otherwise so worthy and brave a man—must bear almost all the blame. His sons and ministers plunder the provinces in an almost unheard of manner; trade and intercourse are almost at a *standstill*; good faith and confidence exist no more. The indolence of the court avoids military expeditions, and anarchy and a lack of security on the routes are the consequences. As two years ago the prince of Zinder could kill the Munioma or prince of Munio, a faithful vassal of the sheikh, and escape unpunished, the people of Khudadza have now slain the prince of Gummel. The sheikh will probably take their presents as indemnification, as he pardoned the sultan of Zinder for the murder of the faithful Munioma for the sake of a few camel-loads. Most of the small princes of the western provinces of Bornu now pay an indeterminate tribute to the prince of Zinder, who on his part has no less ambition than to become master of Bornu. Thus the sheikh and the land grow poorer and poorer, and public morality sinks lower and lower."

BOROUGH. Although the idea of self-government by a town is exemplified in the *coloniæ* and *municipia* of Rome, and in their *duumviri*, *decuriones*, and lesser senate, composed of the curial orders, which along with the *defensor civitatis* appear to have existed in vigour until the reign of Leo the Philosopher (*Const.*, 46, 47), yet as the local power was gradually subordinated to the imperial, and as both in France and Italy it seems almost universally to have disappeared when the territorial jurisdictions, as well as the feudal fiefs, became hereditary, it is impossible to trace an historical connection between these institutions and the modern borough. In Spain and Languedoc, perhaps, the forms of ancient independence may have been continuously preserved, but the system of government by *comes* and *scabini* (or assessors), which was pursued in both France and Italy by the successors of Charlemagne, was obviously opposed to the freedom of towns. It is during the 11th and 12th centuries that we begin to read in charters of the *citizens* of Narbonne, the *burgesses* of Carcassonne, the *consuls* of Beziers, the *magistrates* of Rouergues, the *capitols* of Toulouse. It is during the reigns of Louis the Fat, Louis the Lion, and Philip Augustus that charters of *commune* become frequent. These charters, which sometimes bear to be granted on account of the poverty of the towns folk, the enormities of the clergy, or the attacks of the local *Seigneurs*, were probably dictated by the pecuniary needs of the Crown; but they attest the growing power—the *de facto* rights of the industrial population. They distinguish between *Bourgeoisies* and *Communes* proper: the former obtained a confirmation of ancient customs, of exemption from feudal jurisdiction, of personal liberty, but they did not obtain an elective municipal government. In Italy the revival of civic autonomy was much more rapid. Although Frederic Barbarossa reserved to himself in the peace of Constance the right of nominating consuls in the Italian towns, Bishop Otho of Frisingen tells us that the imperial influence did not count for much; and in 1288, at least, we have in the Potestas (Podesta), the Concilium Generale, and Concilium Novem Dominorum of Siena, a type of the independent republican city.

The Saxon *byrig* or *burh* is properly the fortified house of the powerful man. Related forms are *burgus* (Latin of 4th century); *burg* (High German); *baurgs* (Gothic); *borg* (Gaelic); *πύργος* (Greek); *bor*, *borc*, and *bourg* (French); and *broch*, a pledge. The *burgensis*, or inhabitant of a walled town, was opposed to *villanus*, or inhabitant of the *villa*, or open town. The Gemot, or assembly of the original township, had the power of making *by*-laws (the Danish prefix means "town"), and of electing the *Gerefa* (Reeve), the *Bydel*, and the Tithing-man or constable, the first of whom represented the assembly in the courts of the hundred and the shire. The *Gemot* also saw to the collection of taxes imposed by the higher courts, the pursuit of criminals, and the search for stolen goods. In mercantile places, such as London and Bath, the chief officer was called Port-Gerefa from the gates in which the market was held.

The freeholder of this period had undoubtedly political as well as personal liberty. Generally speaking, however, although common property may have been held by a guild or corporation, and special privileges of trade or inheritance may have been enjoyed, there is before the Conquest little trace of municipal organization. The Lagemanni of Lincoln and the Justices of Chester were apparently among the most ancient resident magistrates, but the manner of their election is unknown. The Conquest divided the boroughs into those which formed part of the royal demesne and those which held of the barons and dignified churchmen,—the interest of the Crown and its grantees in the property and in the profits of fairs and markets, &c., being, at first absolute, but latterly converted into a *firma burgi* or perpetual rent from the whole borough in lieu of tribute from individual *burgesses*. The non-elective bailiff succeeded to the reeve, and proved a useful agent in carrying out the oppressive and arbitrary *tallagia*, which were often the price of new or confirmed privileges. The bailiwicks were sometimes farmed out, and this led to still more severe exaction. To the bailiff succeeded the mayor (major), who accounted to Exchequer for the annual rents of the borough. Grants of jurisdiction, of *socan* and *sacan*, of *outfangenthef* and *infangenthef*,

and grants of the right of appointing *præpositi* (provosts), *ballivi* (from Greek βάλλειν or Latin *bajulus*), and *justiciarii* increase in number towards the reign of John, and are probably included along with the various exemptions from tolls, &c., granted by Henry II. in the "liberties and free customs" guaranteed by the Great Charter. The terms alderman, capital citizen, capital burgess, and jurat were of fluctuating signification; but the last three were finally applied to members of the Common Council which gradually took the place of the assembly of incorporated burgesses. The rights of a free burgess might be acquired by birth, apprenticeship, marriage, or purchase; and as prior to Edward III.'s Laws of the Staple these rights included exclusive privileges of trade, they were properly connected with the payment of local taxation and the performance of local duties, from which non-freemen (strangers and temporary residents) were exempt. In many cases it is probable that the "civitas," or community of freemen, was identical with the *convivium conjuratum*, or Secular Frith Guild of traders and craftsmen, possessing portions of town land. Such voluntary associations for protection of trade, the administration of common property, or for religious and charitable purposes, were more highly developed in England than in any other part of Europe. The members of the leading industry naturally assumed the direction of municipal affairs, and when their guild was recognized by the Crown their bye-laws acquired a binding force. For instance, in deeds of the 12th century relating to the magistrates of Paris the terms *burgenses* and *mercatores per aquam* are used as synonymous. (Brentano on Gilds.) Such guilds gave compensation to brethren who had incurred losses by shipwreck or undeserved misfortune, and made gratuitous loans to poorer brethren for carrying on their trade. It was their special endeavour to obtain staple right, the right of coinage, immunity from tolls, &c. Gradually, however, the distinction arose between the merchants proper who formed the *gildæ mercatoriæ*, and the craftsmen, who had at first traded in the raw materials they worked with, but who were now oppressed and deprived of civic rights by their wealthier brethren. The man "with dirty hands" or "blue nails," the man "without hearth or honour, who lives by his labour," or "hawks his wares in the streets," was threatened with a serfdom like that which the barons and bishops had imposed. But at this juncture the great craft guilds arose to assert the rights of manufacture. In the time of Henry VI. their victory in England was complete, and the Crown, which had previously recognized the constitution and liberties of a town by confirming the guild, now used in its charters the words of express incorporation (*communitas perpetua et corporata*). A glance at the names and forms of the most modern municipality will show how closely trade organization and burghal government have been intertwined.

In Ireland the earliest traces of burghal life are connected with the maritime settlements on the southern and eastern coast. The invasion of Henry II. colonized these Ostman ports with Anglo-Norman communities, who brought with them, or afterwards obtained, municipal charters of a favourable kind. The English settlement obviously depended on the advantages which the burgesses possessed over the native population outside. Quite different from these were the new close boroughs which during the plantation of Ulster James I. introduced from England. The conquest was by this time completed, and by a rigorous enforcement of the Supremacy and Uniformity Acts the existing liberties of the older boroughs were almost entirely withdrawn. By the new rules published (in terms of the Acts of Settlement and Explanation) in 1672 resident traders were permitted to become freemen, but neither this regulation nor the ordinary admissions through birth, marriage, and apprenticeship succeeded in giving to Ireland free and vigorous municipalities. The corrupt admission of non-resident freemen, in order to outvote the ancient freeholders in parliamentary elections, and the systematic exclusion of Roman Catholics, soon divorced the "commonalty" from true local interests, and made the corporations, which elected themselves or selected the constituency, dangerously unpopular.

In Scotland burghs or burrows are divided into Royal Burghs, Burghs of Regality, and Burghs of Barony. The first were erected by Royal Charter, and every burgess held direct of the Crown. It was, therefore, impossible to subfeu the burgh lands,—a distinction still traceable in modern conveyancing. Where perhaps no charter ever existed, the law on proof of immemorial possession of the privileges of a Royal Burgh has presumed that a charter of erection once existed. The charter gave power to elect provost, bailies (French terms which superseded the ancient mayor and aldermen), and council, a power long exercised under the Act 1469, which directs the new council to be chosen annually by the retiring council, and the magistrates by both councils. The jurisdiction of these magistrates, which was specially reserved in the Act of 1747 abolishing heritable jurisdictions, was originally cumulative with, and as large as, that of the sheriff. It is now confined to police offences, summary ejections, orders for *interim* aliment (for prisoners), payment of burgh dues, and delivery of title deeds. Three head courts were held in the year, at which all burgesses were obliged to attend, and at which public business was done and private transactions were ratified. There were three classes of burgesses—burgesses *in sua arte*, members of one or other of the corporations; burgesses who are guild brothers; and simple burgesses. The Leges Burgorum apparently contemplate that all respectable inhabitants should have the franchise, but a ceremony of admission was required, at which the applicant swore fealty and promised to watch and ward for the community, and to pay his "maill" to the king. These borough maills, or rents, and the great and small customs of burghs, formed a large part of the royal revenue, and, although frequently leased or feued out for a fixed duty, were on the accession of James I. annexed to the Crown as an alimentary fund. Burgh customs still stand in the peculiar position of being neither adjudgeable nor arrestable; they are therefore bad security. The early charters contain the usual privileges of holding a market, of exemption from toll or tribute, and that distraint will be allowed only for the burgess's own debts. There was also the usual strife between the guildry and the craftsmen, who were generally prohibited from trading, and of whom dyers, fleshers, and shoemakers were forbidden to enter the guildry. Deacons, wardens, and visitors were appointed by the crafts, and the rate of wages was fixed by the magistrates. The crafts in Scotland were frequently incorporated, not by Royal Charter, but, as in the case of the cordiners of Edinburgh, by seals of cause from the corporation. The trade history of the free burghs is very important. Thus in 1466 the privilege of importing and exporting merchandize was confined to freemen, burgesses, and their factors. Ships are directed to trade to the king's free burghs, there to pay the customs, and to receive their *cocquets* or custom-house seals; and in 1503 persons dwelling outside burghs are forbidden to "use any merchandize," or to sell wine or staple goods. An Act of 1633, erroneously called a *Ratification* of the Privileges of Burghs, extended these privileges of buying and selling to retail as well as wholesale trade, but restricted their enjoyment to Royal Burghs. Accordingly, in 1672, a general declaratory Act was passed confirming to the freemen in Royal Burghs the wholesale trade in wine, wax, silk, dyeing materials, &c., permitting

generally to all persons the export of native raw material, specially permitting the burgesses of Barony and Regality to export their own manufactures, and such goods as they may buy in "markets," and to import against these consignments certain materials for tillage, building, or for use in their own manufactures, with a general permission to retail all commodities. This extraordinary system was again changed in 1690 by an Act which declared that freemen of Royal Burghs should have the sole right of importing everything by sea or land except bestial, and also of exporting by sea everything which was not native raw material, which might be freely exported by land. The gentry were always allowed to import for their personal consumption and to export an equal quantity of commodities. The Act mentions that the Royal Burghs as an estate of the kingdom contributed one-sixth part of all public impositions, and were obliged to build and maintain prison-houses. Some of these trade privileges were not abolished till the Act 9 and 10 Vict. c. 17.

In the north of Scotland there was an association of Free Burghs called the Hanse or *Ansus;* and the Lord Chamberlain, by his *Iter*, or circuit of visitation, maintained a common standard of right and duties in all burghs, and examined the state of the "common good," the accounts of which in 1535 were appointed to be laid before the auditors in Exchequer. The Chamberlain latterly presided in the Curia Quatuor Burgorum (Edinburgh, Berwick, Stirling, Roxburgh), which not only made regulations in trade, but decided questions of private right (*e.g.*, succession), according to the varying customs of burghs. This court frequently met at Haddington; in 1454 it was fixed at Edinburgh. The more modern Convention of Royal Burghs (which appeared as a judicial *persona* in the Court of Session so late as 1839) probably dates from the Act of James III. (1487, c. 111), which appointed the Commissioners of Burghs, both north and south, to meet yearly at Inverkeithing "to treat of the welfare of merchandize, the good rule and statutes for the common profit of burghs, and to provide for remeid upon the skaith and injuries sustained within the burghs." Among the more important functions of this body (on whose decrees at one time summary diligence proceeded) were the prohibition of undue exactions within burghs, the revisal of the "set" or mode of municipal election, and the *pro rata* division among the burghs of the parliamentary subsidy required from the Third Estate. The Convention still meets, but the reform of the municipalities, and the complete representation of the mercantile interests in the United Parliament, have deprived it of importance. In its great days it negotiated a treaty with Campvere, and one of its judgments was given effect to by Edward I. in the Parliament of Newcastle, 1292.

Burghs of Regality and of Barony held in vassalage of some great lordship, lay or ecclesiastical, but were always in theory or in practice created by Crown grant. They received jurisdiction in civil and criminal matters, generally cumulative with that of the Baron or the Lord of Regality, who in some cases obtained the right of nominating magistrates. Powers to hold markets and to levy customs were likewise given to these Burghs.

The Scotch burghs emerged slowly into political importance. In 1295 the procurators of six burghs ratified the agreement for the marriage of Edward Balliol; and in 1326 they were recognized as a Third Estate, granting a tenth penny on all rents for the king's life, if he should apply it for the public good. The Commissioners of Burghs received from the Exchequer their costages or expenses of attending Parliament. The burghs were represented in the Judicial Committee, and in the Committee on Articles appointed during the reign of James V. After the Reformation, in spite of the annexation of kirk lands to the Crown, and the increased burdens laid on temporal lands, the proportion of general taxation borne by the burghs (viz., 1s. 6d.) was expressly preserved by Act 1587, c. 112. The number of commissioners, of course, fluctuated from time to time. Cromwell assigned ten members to the Scotch burghs in the second Parliament of Three Nations (1654). The general practice until 1619 had been, apparently, that each burgh should send two members. In that year (by an arrangement with the Convention of Burghs) certain groups of burghs returned one member, Edinburgh returning two. Under Art. 22 of the Treaty of Union the number of members for Royal Burghs was fixed at fifteen, who were elected in Edinburgh by the Magistrates and Town Council, and in the groups of burghs by delegates chosen *ad hoc*. See PARLIAMENT. (See Connel, *History of the Constitution of Towns;* Stubbs, *Constitutional History of England*, vol. i.) (W. C. S.)

BOROUGH-ENGLISH, a custom prevailing in certain ancient boroughs, and in districts attached to them (where the lands are held in socage), and also in certain copyhold manors (chiefly in Surrey and Middlesex), by which in general lands descend to the youngest son, to the exclusion of all the other children, of the person dying seized and intestate. Descent to the youngest brother to the exclusion of all other collaterals, where there is no issue, is sometimes included in the general definition, but this is really a special custom to be proved from the Court-Rolls of the manor and from local reputation,—a custom which is sometimes extended to the youngest sister, uncle, aunt. Generally, however, Borough-English, apart from specialties, may be said to differ from gavel-kind in not including collaterals. It is often found in connection with the distinct custom that the widow shall take as dower the whole and not merely one-third of her husband's lands. (See Third Report of Real Property Commission, and case of Muggleton *v.* Barnett, 2 Hurls. and Nor. Rep.)

BOROVICHI, a town of Russia, in the government of Novgorod, situated in 58° 23′ N. lat. and 23° 54′ E. long., on both banks of the River Msta. On the site of the present town there existed, from an early date, a settlement famous for the skill of its pilots; and for their encouragement in that occupation the inhabitants were freed from taxation by Peter I. In 1770 the village was raised to the rank of a town, and in 1776 was made the head of a department in the Novgorod government. It contains seven or eight churches and a monastery, an almshouse, and a hospital. Flour, malt, beer, tallow, earthenware, and bricks are all manufactured, but none of them to any great extent. The principal articles of trade are linen, leather, and wood. There are two annual fairs, and a weekly market. Population in 1867, 9108.

BOROVSK, a town of Russia, in the government of Kaluga, 54 miles from that city on the old post road to Moscow, is situated on both banks of the Protva at the confluence of the Tikizh, in 55° 13′ N. lat. and 36° 9′ E. long. The town was in existence in the 13th century, and derived its name from the Borh, or pine forest, which still lies to the N.W. Its principal industries are tanning, soap-boiling, and the manufacture of wax, linseed-oil, and pottery; and it has a trade of considerable importance in grain, hemp, and cloth. There are four annual fairs, two of which are held in the town and two about two miles off, at the monastery of Paphnutius, which was founded in 1444. The population, mainly belonging to the Greek Church, was in 1860, 8150.

BORROMEAN ISLANDS, a group of four small islands on the western side of Lago Maggiore, in Northern Italy, beautifully surrounded by lake and mountain. Naturally mere barren rocks, they were in 1671 converted by Vitaliano Borromeo into pleasure gardens of great

beauty, the soil being transported from the neighbouring shores of the lake. The two most celebrated are the Isola Bella and the Isola Madre. The former rises 130 feet above the level of the water, in ten successive terraces, the highest of which is paved and surrounded by a balustrade, while all are environed by gigantic marble statues of various figures, and the walls are clothed with the finest fruit-trees and evergreens. There is, besides, towards the western end of the island, and close to the lake, a magnificent palace, built on arches, which are formed into grottos, with floors of mosaic and decorations of shell-work and marble. Isola Madre, which is the largest of the group, lies between one and two miles from Isola Bella, and consists of a superstructure of seven terraces, not less beautiful than the other. Here also there is a palace, now dilapidated, with similar decorations. A richly-coloured description of the place is given in his "Titan," by Jean Paul Richter.

BORROMEO, Carlo, saint and cardinal of the Roman Catholic Church, was the son of Ghiberto Borromeo, count of Arona, and of Mary of Medici, and was born at the Castle of Arona, upon the Lago Maggiore, in the Milanese, October 2, 1538. When he was about twelve years old, Julius Cæsar Borromeo resigned to him an abbacy, the revenue of which he applied wholly in charity to the poor. He studied the civil and canon law at Pavia under the learned Francis Alciat. In 1554 his father died; and, although he had an elder brother, Count Frederick, he was requested by the family to take the management of their domestic affairs. After a time, however, he resumed his studies, and in 1559 he took his doctor's degree. In the following year his uncle Cardinal de' Medici was raised to the pontificate, by the name of Pius IV.; and Borromeo was made prothonotary, entrusted with both the public and privy seal of the ecclesiastical state, created cardinal deacon, and soon after raised to the archbishopric of Milan. In compliance with the pope's desire, he lived in great splendour; yet his own temperance and humility were never brought into question. He established an academy of learned persons, and published their memoirs as the *Noctes Vaticanæ*. About the same time he also founded and endowed a college at Pavia, which he dedicated to Justina, virgin and martyr. Upon the death of his elder brother Frederick, his friends advised him to quit the church and marry, that his family might not become extinct. Contrary to expectation, however, he declined the proposal; and from that time became more fervent than ever in exercises of piety, and more zealous for the welfare of the church.

On the death of Pius IV., January 7, 1566, the skill and diligence of Borromeo materially contributed to stifle the cabals of the conclave. As soon as tranquillity had been re-established he devoted himself wholly to the reformation of his large and important diocese, where the most flagitious irregularities were openly practised. He began by making pastoral visits in his metropolis; and by a variety of wise and necessary regulations, he soon restored proper decency and dignity to divine service. In conformity to the decrees of the Council of Trent, he cleared the cathedral of its gorgeous tombs, rich ornaments, banners, arms, not even sparing the monuments of his own relations. He also divided the nave of the church into two compartments for the separation of the sexes. He proceeded next to the collegiate churches, and even to the fraternities of penitents, particularly that of St John the Baptist. The reformation of the monasteries followed that of the churches; and the vigilance of the archbishop soon extended itself from the city to the country round it. The great abuses which had overrun the church at this time arose principally from the ignorance of the clergy. In order, therefore, to attack the evil at its root, Borromeo established seminaries, colleges, and communities, for the education of young persons intended for holy orders. He met with much opposition in his endeavours to bring about his reforms, but succeeded, nevertheless, in rendering the most important services to the cause of morals as well as religion. The governor of the province, and many of the senators, apprehensive that the cardinal's ordinances and proceedings would encroach upon the civil jurisdiction, addressed many remonstrances and complaints to the courts of Rome and Madrid. But Borromeo had more formidable difficulties to struggle with, in the inveterate opposition of several religious orders, particularly that of the Brothers of Humility. Some members of that society formed a conspiracy against his life, and a shot was one evening fired at him in the archiepiscopal chapel under circumstances which led to the belief that his escape was miraculous.

In the year 1576 the city and diocese of Milan were visited by the plague, which swept away great numbers. On this occasion he went about giving directions for accommodating the sick and burying the dead, avoiding no danger, and sparing no expense. He also visited all the neighbouring parishes where the contagion raged, distributing money, providing accommodation for the sick, and punishing those, especially the clergy, who were remiss in discharging the duties of their calling.

But continual labours and austerities appear to have shortened his life. He was seized with an intermittent fever, and died at Milan, November 4, 1584. He was immediately enrolled among the saints, but was not canonized till 1610. Besides the *Noctes Vaticanæ*, to which he appears to have contributed, the only literary relics of this intrepid and zealous reformer are some homilies, discourses, and sermons, with a collection of letters. Several lives of him have been published,—by Godeau; by Touron, a Dominican; by Ribadeneira, a Spanish Jesuit; by Bimeus, and by others.

BORROMINI, Francesco, an Italian architect, born at Bissone in 1599. He was much employed in the middle of the 17th century at Rome. In his style he affected originality and richness, which corrupted the noble simplicity of the older schools, though his compositions are occasionally imposing. His principal works are the church of St Agnese in Piazza Navona, the church of La Sapienza in Rome, the church of San Carlino alle Fontane, the church of the Collegio di Propaganda, and the restoration of San Giovanni in Laterano. He died by his own hand at Rome in 1667. Engravings of his chief compositions are to be found in the posthumous work *Francisci Borromini opus Architectonicum*, 1727.

BORROWSTOUNNESS (usually abbreviated to Bo'ness), one of the oldest seaports of Scotland, is situated on the Firth of Forth, in Linlithgowshire, about four miles from the county town, in 56° 2′ N. lat. and 3° 35′ W. long. The town is very irregularly built, contrasting unfavourably with the beauty of its situation. It was formerly a place of considerable traffic, ranking in the 18th century immediately after Leith; but it has been for a long time left far behind by the neighbouring seaport of Grangemouth. Its harbour, with an area of 2½ acres, being too small for the trade of the port, a bill has been passed in Parliament for a large extension. The commerce is now for the most part confined to the Baltic, and the principal import consists of wooden props for use in mines. The value of the total imports in 1873 was £150,059, and of the total exports in the same year £223,539. There are extensive manufactories of salt, distilleries, a pottery, ropeworks, and vitriol and soap-works; but the collieries and iron-stone pits in the immediate neighbourhood are much more important. Some of the former have been worked for

centuries, and extend under the firth to the distance of a mile. The smelting of the iron-ore is carried on in two or three blast-furnaces in the neighbourhood of Kinniel House, which was for many years the residence of Dugald Stewart. A part of Graham's Dyke, the Roman wall of Antoninus, runs through the parish. Population in 1871, 4256.

BORY DE SAINT-VINCENT, JEAN BAPTISTE GEORGE-MARIE, a learned and industrious French naturalist, was born at Agen in 1780. While a mere boy he displayed the scientific bent of his genius and attracted attention by two memoirs addressed to the Society of Natural History at Bordeaux. Having been sent as naturalist of Baudin's expedition to Australia in 1798, he left the vessel at the Mauritius, and spent two years in exploring Bourbon and the other islands of East Africa. Joining the army on his return, he was present at the battles of Ulm and Austerlitz, and in 1808 went to Spain with Marshal Soult. His attachment to the Napoleonic dynasty and dislike to the Bourbons were shown in various ways during 1815, and his name was consequently placed on the list of the proscribed; but after wandering in disguise from one city to another he was allowed quietly to return to Paris in 1820. In 1829 he was placed at the head of a scientific expedition to the Morea, and in 1839 he had charge of the exploration of Algeria. Through all the vicissitudes of his life his literary activity was great, and he did a great deal for the popularization of his favourite science. He was editor of the *Dictionnaire classique d'histoire naturelle*, and one of the principal authors of the *Annales des sciences physiques*; the official work on the Morea was produced under his care, and he contributed frequently to periodical publications. The most important of his separate productions are—*Essais sur les îles Fortunées*, 1803; *Voyage dans les îles d'Afrique*, 1804; *Justification de la conduite et des opinions politiques de J. B. Bory de Saint-Vincent*, 1816; *Voyage Souterrain*, being an account of the quarries in the neighbourhood of Maestricht, 1823; *L'Homme, essai zoologique sur le genre humain*, 1827; *Résumé de la géographie de la Péninsule*, 1838.

BOSA, a city on the western coast of the island of Sardinia, in the province of Cagliari and district of Oristano, in a fine valley on the northern bank of the Terno, in 40° 16' 10" N. lat. and 8° 25' 31" E. long. It is the see of a bishop, and has a cathedral and a diocesan seminary. The harbour is safe, being sheltered by an islet. Coral fishery is carried on, and there is trade in cheese, grain, and wine. Population, 6706.

BOSC, LOUIS AUGUSTINE GUILLAUME, French naturalist, was born at Paris on the 29th January 1759. He was educated at the college of Dijon, and attended the lectures of Durande on botany, which inspired him with a passion for natural history. He followed up his studies at Paris, and was a constant auditor at the Jardin des Plantes. Even when closely occupied in official work, he managed to find time for his favourite researches and contributed many valuable papers to various scientific transactions and reviews. At the age of eighteen he had obtained an appointment under Government, and he rose to be one of the chief officials in the postal department. Under the ministry of Roland he also held the post of superintendent of prisons, but the violent outbreaks of 1793 drove him from office, and compelled him to take refuge in flight. For some months he lay concealed in the forest of Montmorency, barely subsisting on roots and vegetables. He was enabled to return to Paris on the fall of Robespierre, and soon after set out for America, resolving to explore the natural riches of that country. The immense materials he gathered were never published in a complete form, but much went to enrich the works of Lacépède, Latreille, and others. After his return, on the establishment of the Directory, he was reinstated in his old office. Of this he was again deprived by the *coup d'état* of 1799, and for a time he was in great destitution. He set resolutely to work, however, and by his copious contributions to scientific literature, contrived to support himself and to lay the foundations of a solid reputation. He was engaged on the Supplement to Rozier's Dictionary, on the new *Dictionnaire d'histoire naturelle*, and on the *Encyclopédie Méthodique*. He edited the *Dictionnaire raisonné et universal d'agriculture*, and was one of the editors of the *Annales de l'agriculture Française*. His increasing fame brought him manifold employments. He was made inspector of the gardens at Versailles, and of the public nurseries belonging to ministry of the Interior. The last years of his life were devoted to an elaborate work on the vine, for which he had amassed an immense quantity of materials. His death, on the 10th July 1828, prevented the prosecution of this work; and his notes which still exist are said to be so unsystematic as to be unfit for publication.

BOSCAN, JUAN, a Spanish poet, celebrated as the introducer of Italian measures into Spanish literature, was born about the close of the 15th century. The exact date is unknown, but it was probably a few years before 1500. He was of patrician birth and appears to have passed some years in military service. He died in 1540 at Perpignan, where he was residing with the duke of Alva. His poems were published in 1543 at Barcelona by his widow. They are divided into four books which mark out distinctly the stages of Boscan's poetical history. The first book contains light poems in the Old Castilian metres, resembling the *Cancioneros*. These were written in his youth, before 1526, in which year he became acquainted with Andrea Navagiero, ambassador from Venice. Navagiero urged him to adopt some of the Italian measures, and his advice gave a new turn to Boscan's activity. The second and third books contain a number of pieces in Italian metres, sonnets, canzones, and poems in blank verse, *terza rima*, and octaves. The longest of these poems is the *Hero and Leander*, in blank verse. The fourth book contains his best effort, the *Allegory*, written in the maturity of his powers, and exhibiting great delicacy of imagination and skilful verse composition. He also published, in 1534, a translation of Balthasar Castiglione's Italian poem *The Courtier*. Boscan's greatest follower in the endeavour to mould Spanish poetry after Italian models was Garcilassa de la Vega, who is more celebrated than his master.

See Bouterwek, *Spanish Literature*, vol. i.; Ticknor, *History of Spanish Literature*, vol. i.

BOSCAWEN, EDWARD, British admiral, was born August 19, 1711. He was the third son of Hugh, Lord Viscount Falmouth. He early entered the navy, and in 1740 distinguished himself at the taking of Porto Bello. At the siege of Carthagena, in March 1741, at the head of a party of seamen, he took a battery of fifteen 24-pounders, while exposed to the fire of another fort. On his return to England in the following year he married, and entered parliament as member for Truro. In 1744 he captured the "Medea," a French man-of-war, commanded by M. de Hocquart, the first ship taken in the war. In May 1747 he signalized himself in the engagement off Cape Finisterre, and was wounded in the shoulder with a musket-ball. Hocquart again became his prisoner and the French ships, ten in number, were taken. On the 15th July, he was made rear-admiral and commander-in-chief of the expedition to the East Indies. On the 29th July 1748 he arrived off Fort St David's, and soon after laid siege to Pondicherry; but the sickness of his men and the approach of the monsoons led to the raising of the siege. Soon afterwards he received news of the peace, and Madras was delivered up to him by the French. In April 1750

he arrived in England, and was the next year made one of the lords of the Admiralty, and chosen an elder brother of the Trinity House. In February 1755 he was appointed vice-admiral, and in April he intercepted the French squadron bound to North America, and took the "Alcide" and "Lys" of sixty-four guns each. Hocquart became his prisoner for the third time, and Boscawen returned to Spithead with his prizes and 1500 prisoners. For this exploit he received the thanks of Parliament. In 1758 he was appointed admiral of the blue and commander-in-chief of the expedition to Cape Breton, when, in conjunction with General Amherst, he took the fortress of Louisbourg, and the island of Cape Breton,—services for which he again received the thanks of tho House of Commons. In 1759, being appointed to command in the Mediterranean, he pursued the French fleet, and after a sharp engagement in Lagos Bay, took three large ships and burnt two, returning to Spithead with his prizes and 2000 prisoners. In December 1760 he was appointed general of the marines, with a salary of £3000 per annum, and was also sworn a member of the privy council. He died at his seat near Guildford, January 10, 1761, in the 50th year of his age.

BOSCOVICH, Roger Joseph, a distinguished Italian mathematician and natural philosopher, and one of the earliest of foreign *savants* to adopt the theory of Newton, was born at Ragusa in Dalmatia, May 18, 1711, according to the usual account, but ten years earlier according to Lalande (*Éloge*, 1792). In his fifteenth year, after passing through the usual elementary studies, he entered the society of Jesus. On completing his noviciate, which was spent at Rome, he studied mathematics and physics at the Collegium Romanum; and so brilliant was his progress in these sciences that in 1740 he obtained the appointment of professor of mathematics in the college. For this post he was especially fitted by his large acquaintance with modern advances in science and by his skill in a classical severity of demonstration, acquired by a thorough study of the works of the Greek geometricians. Several years before this appointment he had made himself a name by an elegant solution of the problem to find the sun's equator and determine the period of his rotation by observation of the spots on his surface. Notwithstanding the arduous duties of his professorship he found time for investigation in all the fields of physical science; and he published a very large number of dissertations, some of them of considerable length, on a wide variety of subjects. Among these subjects were the transit of Mercury, the Aurora Borealis, the figure of the earth, the observation of the fixed stars, the inequalities in terrestrial gravitation, the application of mathematics to the theory of the telescope, the limits of certainty in astronomical observations, the solid of greatest attraction, the cycloid, the logistic curve lines, the theory of comets, the tides, the law of continuity, the double refraction micrometer, various problems of spherical trigonometry, &c. In 1742 he was consulted, with other men of science, by the pope, Benedict XIV., as to the best means of securing the stability of the dome of St Peter's, in which a crack had been discovered. His suggestion was adopted. Shortly after he engaged to take part in the Portuguese expedition for the survey of Brazil and the measurement of a degree of the meridian; but he yielded to the urgent request of the pope that he would remain in Italy and undertake a similar task there. Accordingly, in conjunction with Christopher Maire, an English Jesuit, he measured an arc of two degrees between Rome and Rimini. The operations were begun towards the close of 1750, and were completed in about two years. An account of them was published in 1755, entitled *De Litteraria expeditione per pontificam ditionem ad dimetiendos duos meridiani gradus a P. P. Maire et Boscovich.* The value of this work was increased by a carefully prepared map of the States of the Church. A French translation appeared in 1770. A dispute having arisen between the Grand Duke of Tuscany and the republic of Lucca with respect to the drainage of a lake, Boscovich was sent, in 1757, as agent of Lucca to Vienna, and succeeded in bringing about a satisfactory arrangement of the matter. In the following year he published at Vienna his famous work on the molecular theory of matter, entitled *Theoria philosophiæ naturalis redacta ad unicam legem virium in natura existentium.*• Another occasion for the exercise of his diplomatic ability soon after presented itself. A suspicion having arisen on the part of the British Government that ships of war had been fitted out in the port of Ragusa for the service of France, and that the neutrality of Ragusa had thus been violated, Boscovich was selected to undertake an embassy to London (1760), to vindicate the character of his native place and satisfy the Government. This mission he discharged successfully, with credit to himself and satisfaction to his countrymen. During his stay in England he was elected a fellow of the Royal Society, which received him with marks of the highest respect. He soon after paid this society the compliment of dedicating to it his Latin poem, entitled, *De Solis et Lunæ Defectibus.* This prolix composition, one of a class which at that time was much in vogue—metrical epitomes of the facts of science—contains in about five thousand lines, illustrated by voluminous notes, a compendium of astronomy. It was for the most part written on horseback, during the author's rides in the country while engaged in his meridian measurements. The book is characterized by Delambre as "uninstructive to an astronomer and unintelligible to any one else."

On leaving England Boscovich travelled in Turkey, but ill health compelled him soon to return to Italy. In 1764 he was called to the chair of mathematics at the University of Pavia, and this post he held, together with the directorship of the observatory of Brera, for six years. He was invited by the Royal Society of London to undertake an expedition to California to observe the transit of Venus in 1769; but this was prevented by the recent decree of the Spanish Government for the expulsion of the Jesuits from its dominions. The vanity, egotism, and petulance of Boscovich provoked his rivals and made him many enemies, so that in hope of peace he was driven to frequent change of residence. About 1770 he removed to Milan, where he continued to teach and to hold the directorship of the observatory of Brera; but being deprived of his post by the intrigues of his associates he was about to retire to his native place, when the news reached him (1773) of the suppression of his order in Italy. Uncertainty as to his future lot led him to accept an invitation from the king of France to Paris, where he was naturalized and was appointed director of optics for the marine, an office instituted for him, with a pension of 8000 livres. He remained there ten years, but his position became irksome, and at length intolerable. He continued however to devote himself diligently to the pursuits of science, and published many remarkable memoirs. Among them were an elegant solution of the problem to determine the orbit of a comet from three observations, and memoirs on the micrometer and achromatic telescopes. In 1783 he returned to Italy, and spent two years at Bassano, where he occupied himself with the publication of his *Opera pertinentia ad opticam et astronomiam, &c.*, which appeared in 1785 in five volumes quarto. After a visit of some months to the convent of Vallombrosa, he went to Milan and resumed his literary labours. But his health was failing, his reputation was on the wane, his works did not sell, and he gradually sank a prey to illness and disappointment. He fell into

melancholy, imbecility, and at last madness, with lucid intervals, and died at Milan on the 13th of February 1787. In addition to the works already mentioned Boscovich published *Elementa universæ matheseos* (1754), the substance of the course of study prepared for his pupils; and a narrative of his travels, entitled *Giornale di un viaggio da Constantinopoli in Polonia*, of which several editions and a French translation appeared. His latest labour was the editing of the Latin poems of his friend Benedict Stay on the philosophy of Descartes, with scientific annotations and supplements. (W. L. R. C.)

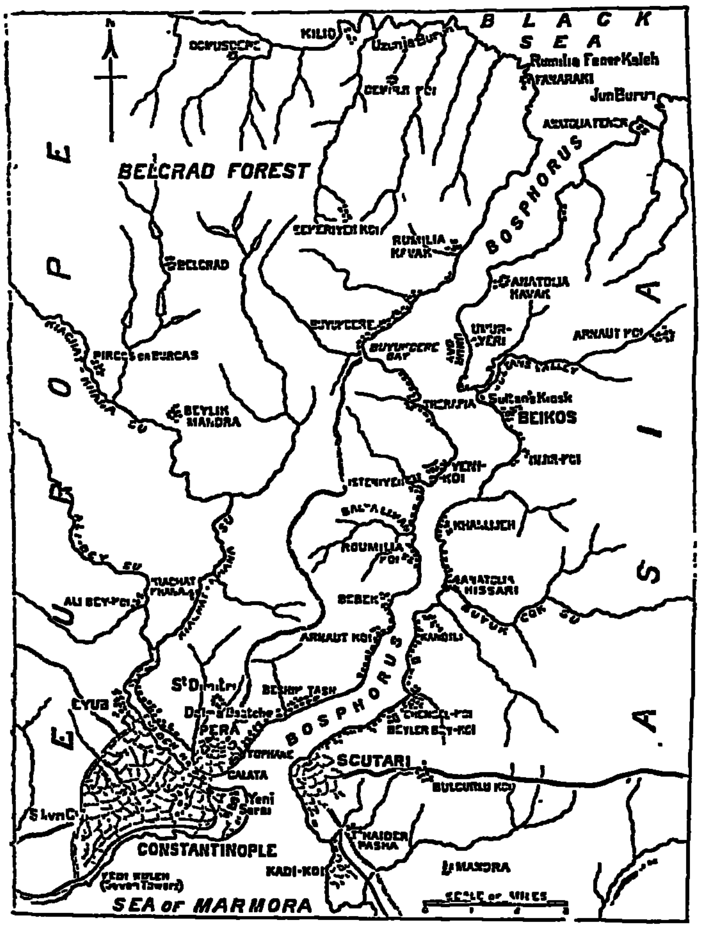
BOSNA SERAI, SERAIEVO, or in Italian SERAGLIO, a city of European Turkey, and capital of the province of Bosnia, is situated on the Migliazza near its junction with the Bosna, 246 miles south of Buda in 43° 54′ N. lat. and 18° 24′ E. long. It occupies the declivities of several small hills, and its numerous turrets give it a rather imposing aspect. It is defended by a strong citadel, and retains portions of its ancient walls. The houses are in general rather meagre, but of late there has been an improvement in the style of architecture, owing to the employment of Austrian and Italian workmen. The old Government buildings have been replaced by a handsome and spacious structure. There are upwards of 100 mosques, several Greek churches, and a few Roman Catholic convents. Educational establishments owe any merit they possess to foreign influence, and notably to the stimulus given by Miss Irby and Miss Mackenzie (afterwards Lady Sebright). Bosna Serai is one of the chief industrial and commercial cities in European Turkey. It manufactures tin, iron, and copper wares, fire-arms, cotton and woollen cloths, and leather, and is the centre of the Bosnian trade. In the neighbourhood are iron mines, and works of considerable extent. The city is the centre of a telegraphic system of some importance, and is well situated for railway communication with both north and south. Bosna Serai, originally called Bosnavar, was founded in 1263 by the Hungarian general Cotroman, and derives its present name from the *Serai* or palace built by Mahomet II. The population is very variously stated; the Prussian consul gives it as about 50,000 in 1865, and in 1867 as not more than 35,000, while Salaheddin Bey, in *La Turquie à l'exposition universale de* 1867, states it as high as 70,000.

BOSNIA, the most north-westerly province of Turkey in Europe, comprising Bosnia Proper, a part of Turkish-Croatia, or Craina, the district of Herzegovina, and the ancient Rascia. It extends from 42° 30′ to 45° 15′ N. lat., and from 15° 40′ to 21° 2′ E. long; is bounded on the N. and W. by the Austrian dominions, S. by Montenegro and Albania, and E. by Servia; and has an area of about 24,024 square miles. The whole province, with the exception of the valley of the Save, is more or less mountainous, many of the summits reaching the height of 6000 feet. A large proportion of the surface is valuable forest-land, which furnishes almost inexhaustible stores of timber and fuel. Plums are largely grown in the northern portion and exported as prunes,—Beska on the Save being one of the chief centres of the trade. In Herzegovina the vine, olive, fig, and pomegranate flourish. Maize and wheat are the principal grains in cultivation, but barley, oats, hemp, and even rice are also grown. Abundance of pasture land occurs throughout the province, and cattle, sheep, and goats are reared; the number of the cattle was, however, greatly diminished by the plague in the decade ending with 1870. Large droves of swine are fed in the oak-forests. In mineral deposits the country is especially rich. The whole valley of the Bosnia is said to be one enormous coal-bed; copper is worked in several places, and at Inatch is a very valuable cinnabar mine. There are also some of the [illegible] good marble, and at Tuzla is a copious spring of salt water from which culinary salt is manufactured, though the demand for this article has still to be met by a foreign supply. The manufactures of the province are on a small scale; they include leather, cloth, and iron wares. The principal exports are fruit, timber, cattle, wool, raw lamb-skins, furs of wild animals, wax, and honey. The foreign trade is almost solely confined to the Austrian dominions,—the lack of a port on the Adriatic greatly impeding the intercourse by sea. Within the last ten years there have been constructed several carriage roads, the most important of which are from the capital to Brood, Gradishka, Mostar, and Yenibazar respectively. A railway has been constructed from Rasnice in Austria to Banyaluka, forming part of a great connecting line between Constantinople and Western Europe. The province is divided into the seven sandjaks of Banyaluka, Bihac, Herzegovina, Yenibazar, Seraievo, Travnik, and Zvornik. Ethnologically it is Servian, not even the aristocracy being Turks, though they are principally Mahometans. A small part of the south has an Albanian population. Mahometanism is not only predominant, but is sometimes enforced by persecution. Education is said to be greatly neglected, though from the native statistics a different judgment might be formed, no fewer than 1079 schools being *registered*; but of these a large proportion are attached to the mosques, and have a merely nominal existence. The total revenue of the province was, in 1871, 50,589,970 piastres (£456,715), and the expenditure, 19,724,745 (£178,070). The population increases very slowly, chiefly owing to mortality among the children occasioned by improper treatment. The climate is by no means unhealthy. The number of the inhabitants has remained almost stationary, being estimated at 1,100,000 in 1844, and at 1,279,296 in 1873. The largest cities after Bosna Serai, the capital, are Banyaluka (15,000), Fotcha, Mostar, Zvornik, and Travnik (about 12,000 each), and Yenibazar (from 9000 to 15,000). Bosnia was at first dependent on the Servian and Croatian kings, but was raised for a time to a separate principality, which reverted about 1339 to the Servian king Stephen. After his death it was again independent, and continued to have its own rulers till the latter half of the 15th century, in spite of the encroachments of the Turks, who at last succeeded in incorporating it in 1503. The Hungarians long disputed this appropriation, but the country was definitely ceded to Turkey at the peace of Carlovitz in 1699, which was confirmed by the treaty of Sistovar in 1791. It is at present (1875) the scene of a formidable insurrection.

See Chaumette Desfosse's *Voy. en Bosnie*, 1822; Pertusier, *La Bosnie*, 1822; Hilferding, *Bosnia, Herczegovina, i staraya Serbia* (in Russian) 1859; Sax, *Skizzen über die Bewohner Bosniens*, 1864; Roskievicz, *Bosnia und Herzegovina*, 1867; Blau in *Zeitschrift für Erdk.*, Berlin, 1868; Rousseau in *Bulletin de la Soc. de Géog.*, 1868; Maurer, *Reise d. Bosnien*, 1870; Geiger and Lebret, *Studien über Bosnien, etc.*, 1873; and a very full report by the English consul Holmes for 1872.

BOSPHORUS (or, more correctly, BOSPORUS, from the Greek Βόσπορος, Ox-ford), originally used for a strait, was especially applied to the *Bosporus Cimmerius*, or Strait of Yenikale, and the *Bosporus Thracius*, or Strait of Constantinople. In modern times it has almost become the exclusive designation of the latter strait, which unites the Black Sea with the Sea of Marmora and forms the boundary between Europe and Asia. The channel is about 16 English miles in length, and has a maximum breadth of nearly 2 miles, a minimum breadth of 550 yards, and along the middle a varying depth of 148 to 388 feet. In the centre there is a rapid current from the Black Sea to the Sea of Marmora, and a counter-current sets in along each shore. At the narrows the three currents produce a most violent commotion. The average temperature of the water hardly differs from that of the air, but it almost never

reaches the atmospheric maxima and minima. The surface is very rarely frozen over, not more than five or six instances being recorded since the 8th century A.D. The Golden Horn was partially frozen over in 1849 and 1862. The shores of the Bosphorus are composed in the northern portion of different volcanic rocks, such as dolerite, granite, and trachyte; but along the remaining course of the channel the prevailing formations are Devonian, consisting of sandstones, marls, quartzose conglomerates, and calcareous deposits of various kinds. The scenery on both sides is of the most varied and beautiful description.



Sketch-Map of the Bosphorus.

BOSSI, GIUSEPPE, an Italian painter and writer on art, was born at the village of Busto Arsizio in the Milanese, in 1776 or 1777. He was educated at the college of Monza; and his early fondness for drawing was fostered by the director of the college, who supplied him with prints after the works of Agostino Carracci for copies. Passing next to the academy of Brera at Milan, he there pursued his special artistic studies, and about 1795 went to Rome. Here he studied for five or six years, associating with many artists of the Italian school, and especially forming an intimate friendship with Canova. On his return to Milan he was named assistant secretary of the Academy of Fine Arts, and on the death of Bianconi succeeded him in the office of secretary. He rendered important service in the organization of this new institution. In 1804, in conjunction with Oriani, he drew up the rules of the three academies of art of Bologna, Venice, and Milan, and soon after was rewarded with the decoration of the Iron Crown. On the occasion of the visit of Napoleon I. to Milan in 1805, Bossi exhibited a drawing of the Last Judgment of Michael Angelo, and pictures representing Aurora and Night, Œdipus and Creon, and the Italian Parnassus. By command of Prince Eugene, viceroy of Italy, Bossi undertook to make a copy of the Last Supper of Leonardo, then almost obliterated, for the purpose of getting it rendered in mosaic. The drawing was made from the remains of the original with the aid of copies and the best prints. The mosaic was executed by Raffaelli, and was placed in the Imperial Gallery of Vienna. Bossi made another copy in oil, which was placed in the museum of Brera. This museum owed to him a fine collection of casts of great works of sculpture acquired at Paris, Rome, and Florence. Bossi devoted a large part of his life to the study of the works of Leonardo; and his last work was a series of drawings in monochrome representing incidents in the life of that great master. He left unfinished a large cartoon in black chalk of the Dead Christ in the bosom of Mary, with John and the Magdalene. In 1810 he published a special work in large quarto, entitled *Del Cenacolo di Leonardo da Vinci*, which had the merit of greatly interesting Goethe. His other works are *Delle Opinioni di Leonardo intorno alla simmetria de' corpi umani* (1811), and *Del Tipo dell' arte della pittura* (1816). Bossi died at Milan, December 15, 1816. A monument by Canova was erected to his memory in the Ambrosian library, and a bust was placed in the Brera.

BOSSI, GIUSEPPE CARLO AURELIO, BARON DE, an Italian poet and diplomatist, was born at Turin, November 15, 1758. He made his first appearance as poet at the age of eighteen by the publication of two tragedies, *Rea Silvia* and *I Circassi*; and four years later he took the degree of doctor of laws. In 1781, in consequence of his ode in praise of the edict of toleration promulgated by the Emperor Joseph II., he was banished the kingdom; but having rendered during his exile an important service to his countrymen he was recalled and appointed under-secretary of state for foreign affairs. In 1792, on occasion of the French invasion, he was sent to the court of Prussia to negotiate an alliance, and thence went as ambassador to St Petersburg. Dismissed by the emperor in consequence of the treaty of alliance between Sardinia and France (1797), he was named ambassador to Venice, which he reached only in time to witness the fall of the republic. He was next appointed envoy to General Bonaparte in Italy. After the conquest of Sardinia Bossi was a member of the Provisional Government, and one of the three deputies sent to Paris to petition for annexation to France. The Russian invasion of 1799 drove him to take refuge in the Vaudois valleys. He was afterwards a member of the Provisional Government, but retired in 1802. Three years later he was made prefect of the Ain, he was created baron by Napoleon I. in 1810, and was afterwards transferred to the prefecture of La Manche. Deprived on the second return of the Bourbons, he came to England, but returned to France the following year. He spent his remaining years in retirement. Besides the works above mentioned Bossi was author of a long poem entitled *Oromasia*, on the events of the French revolution; *Monaca*, a poem on the secularization of convents (1787); and various lyrical pieces, among which are *Independenza Americana* (1785), *Olanda Pacificata* (1788), *Visione* (1799), &c. He died at Paris, January 20, 1823.

BOSSU, RENÉ LE, an eminent French critic, born at Paris, March 16, 1631. He studied at Nanterre, and in 1649 entered among the regular canons of Sainte-Geneviève. After having acted as professor in different religious houses for twelve years, he withdrew into retirement. His first publication was *Parallèle des Principes de la Physique d'Aristote et de celle de René Descartes*, which appeared in 1674, but met with little success. His next work, entitled *Traité du Poëme Épique*, was published in

1675 and often reprinted afterwards. Its leading doctrine is that the subject should be chosen before the characters, and that the action should be arranged without reference to the personages who are to figure in the scene. Boileau, in his *Third Reflexion on Longinus*, pronounced this work "l'un des meilleurs livres de poétique qui, du consentement de tous les habiles gens, aient été faits en nôtre langue." It may be mentioned, however, that Bossu is said to have defended Boileau against Saint-Sorlin, and to have received his thanks for that service; and a sense of obligation may perhaps have dictated the commendation which Boileau bestowed on the work. Bossu died March 14, 1680.

BOSSUET, JACQUES BÉNIGNE, the celebrated orator and prelate, was born at Dijon, within a short distance of the cathedral, on the 27th September 1627. He was the fifth son of Bénigne Bossuet and Madeleine Mochette. The family of which he came, though of bourgeois rank, had long taken an honourable part in the public and official life of Burgundy. He was destined from infancy for the church, and grew up amid influences eminently favourable to the unfolding of his powers, for, although at six years of age, on his father's appointment to be president in the parliament of Metz, he was left at Dijon, yet his education had been wisely confided to an uncle, Claude Bossuet, a large-hearted man, ardently devoted to literature, whose delight it was to foster his nephew's intellectual gifts. These soon gave token of exceptional brilliancy, and in the Jesuits' College, where he went to school, he distanced all competitors in the facility with which he mastered the Greek and Latin classics, Virgil and Homer being his especial favourites, for whose writings he contracted an unalterable attachment, just as Horace became the life-long companion of his rival Fénélon. It was from a higher source, however, that Bossuet's genius, which was essentially of the Hebrew type, caught its finest inspiration; and one day reading a Bible left open by accident at the prophecies of Isaiah, he was so thrilled by their poetry that thenceforth he became virtually "a man of one book," and in Holy Scripture, read and re-read until learned ultimately almost by heart, he found the field in which his mind could best expatiate and gather light and power. In Bossuet, says Lamartine, the Bible was transfused into a man. With that keen-sighted appreciation of talent which they uniformly display, the Jesuits sought to enlist him in their order, but family influence being against the proposal, in 1642 he was sent to Paris; nor could the circumstances of his arrival there fail profoundly to impress the fervid imagination of the boy, for it chanced to be on the very day on which Richelieu, then near his end, was borne into the city in a splendid movable chamber, at the close of the vengeance-taking campaign, which terminated in the execution of De Thou. Bossuet entered the college of Navarre, the oldest in the University, where, under Nicholas Cornet, the presiding genius of the place, and in midst of the intellectual quickening imparted to it in common with the whole of learned Europe by the new philosophy of Descartes, he achieved distinction in every department except mathematics, for which he seems to have possessed neither the taste nor the faculty. At sixteen his attainments were the talk of the town. He became the pet of the lettered aristocracy of Paris, and it argues his strength of character that he was unspoiled by their caresses. The applause which greeted the delivery of his thesis for the bachelor's degree encouraged him to perfect his superb oratorical gifts, nor did he count it unlawful then to be a frequent spectator when the *chefs-d'œuvres* of Corneille were played, although, later, he was not sparing in his criticism of the stage. At twenty-four he was appointed archdeacon of Metz. In Lent 1652, after a season of retreat at St Lazare, he received priest's orders, and immediately quitted the gay capital, and the career already opening to him there, to fulfil the duties awaiting him in the comparative obscurity of the provinces. Six years were spent in unwearied pastoral activity, as well as in exhaustive private study of Scripture and of the Fathers, notably St Augustine, although even in the less read Patristic writings he was at home, and quickly put his knowledge to use in a work of controversy entitled *Refutation du Catechisme de Paul Ferry*, a Protestant minister of Metz. It is of interest principally because it outlines even at that early date the doctrine afterwards vigorously defended by Bossuet of the limited authority of the popes in matters of faith. The echo of his pulpit eloquence had already begun to reach beyond Lorraine; during a short residence at Metz it fascinated Anne of Austria, the Queen Mother, and for the next ten years (1659–69) he was in perpetual request in the metropolis. Wherever he appeared court and city flocked to listen; the queens went from the palace and the nuns of Port Royal from their seclusion; Condé, Turenne, Madame de Sevigné, and other famous contemporaries mingled with the crowd; while, in 1662, the preacher's triumph reached a climax, when after hearing him for the first time at the Louvre, Louis XIV., in a moment of rarely awakened enthusiasm, despatched a royal message to Bossuet's father—"pour le feliciter d'avoir un tel fils."

According to Lachet, these matchless discourses may be classified as belonging to three periods:—that of Metz, showing a considerable measure of crudeness both of thought and expression; that of Paris, distinguished by strength and splendour (for, as Sainte-Beuve observes, every trace of immaturity or questionable taste disappears from the moment when Bossuet enters the circle of the king's influence); and that of Meaux, in which faultless grace of composition is purchased at the expense of vigour. On ordinary occasions, and for an audience that loved the practical truths of religion marshalled with logical force and distinctness, Bourdaloue was, perhaps, equally attractive as a preacher—there is even more contemporary talk about him; but in the *Oraisons Funèbres* Bossuet is unapproachable. In this species of oratory Mascaron and Flechier had preceded him, but he is the veritable creator of it, and nowhere does his genius take such wing as at the grave's mouth, when, recounting the virtues of the illustrious dead, he pictures, with wonderful sweep of imagination and mastery of detail, the historical events and personages of the epoch in which they lived, the more impressively to demonstrate that all earthly pomp and renown "are shadows, not substantial things." Not that he altogether escapes the vice of the French pulpit of that age, for occasionally he does elevate into types of excellence those who fell far short of it; but, as compared with other offenders, the adulation which he offers is, even in the hearing of royalty, measured and temperate. His funeral orations at the death of Henrietta of England, of her daughter, the duchess of Orleans, and of the great Condé, are commonly deemed his finest efforts of the kind.

In 1669 Bossuet was appointed to the diocese of Condom, and in the year following he became preceptor to the Dauphin; but being unable, in conscience, to retain both offices he resigned the former, and, in consideration of the pecuniary sacrifice involved, obtained the revenues of the Abbey of St Lucien at Beauvais. Convinced that on the culture of the Dauphin might depend the future welfare of the French people, he threw himself with incredible energy into the novel duties of the preceptorship, and resumed his own education the better to educate his august but indolent pupil. He lacked that sweetness of nature, however, which afterwards gave to Fénélon such sway over the Dauphin's son. For the edification of his royal charge Bossuet wrote several able works, such as

L'Histoire abregée de la France; *La Politique sacrée*; *Traité de la connaissance de Dieu et de soimême*; and most celebrated of al., *Le Discours sur l'histoire universelle*. This work, originally meant to be a mere abridgment for use in the royal schoolroom, grew as he wrote into a magnificent historical narrative. It consists of three parts:—(1), a sketch of history from Genesis to the birth of the modern world under Charlemagne; (2), an account of the Mosaic and Christian economies; (3), a series of reflections on the vicissitudes of human government,—the whole being characterized by splendour of colouring and vast range of plan, although this latter feature is less striking in late editions than in the earliest, which was not broken up into chapters. In the composition of it Leibnitz greatly helped him, by forwarding from Germany every book bearing on the subject on which he could lay hands. Its central thought is that of all changes in history being overruled with sole reference to the progress and universality of true religion; but Bossuet's treatment of this theme, notwithstanding a host of striking and unchallengeable observations, is vitiated by his identification of the Christian faith exclusively with the Papal form of it, and by the way in which he ignores the place and value of pagan antiquity in the world's development, so as to invite, if not to justify, the sneer of Voltaire: "Il parait avoir écrit uniquement pour insinuer que tout a été fait dans le monde pour la nation juive."

It was not until the close of 1679 that Bossuet's official duties as preceptor came to an end, but in the interval his industry otherwise did not slacken. He was elected a member of the Academy of France in 1671. About this time, too, he gave to the world the most frequently revised, most bitterly attacked, and most widely translated of all his books, *L'Exposition de la doctrine catholique*. Composed in 1669, and originally circulated in manuscript, it had been credited with effecting in this shape not a few conversions, among others that of Turenne. But Jean Daillé and other Reformers having charged it with toning down the harshness of Roman dogma with the purpose of ensnaring their flocks, Bossuet resolved to publish it. The book created a wide-spread flutter of excitement, as may be inferred from the terms employed in speaking of it by Jurieu, perhaps the ablest of Bossuet's opponents,—"Everybody is gone mad over the *Exposition*; everywhere one hears of the most disgraceful perversions." It twice received the *imprimatur* of the Pope in despite of the author's undisguised opinions with respect to infallibility. Curiously enough, it was this treatise that brought about in 1678 the conference between Bossuet and Claude, the learned pastor of Charenton. Floquet informs us that wherever he could obtain a face to face encounter, Bossuet preferred it to controversial writing. On the present occasion the discussion lasted five hours, turning on the authority of the church, with what result is, perhaps, not unfairly described by Bayle in the pithy remark—"That as at the battle of Seneff, both sides claimed the victory."

During the latter years of the preceptorship Bossuet, with a few genial associates, busied himself with *Notes and Annotations of the Books of Scripture*. Many pleasant hours were spent in these round-table studies, and it is proof of his inexhaustible energy that he did not hesitate, even so late in life, to acquire a knowledge of Hebrew, though there may be a touch of exaggeration in what was said of him by an admirer,—"that he was not less familiar with the language of Moses than with that of Homer." His life at court was not without its shadows. His very position involved him unwillingly in the miserable transactions springing out of the unhallowed relation in which the king stood to his successive favourites. But Bossuet never forgot the bishop in the courtier. He remonstrated often and seriously with the profligate Louis. As spiritual adviser of the beautiful but unhappy La Vallière, his Christian gentleness and wisdom shine out conspicuously in the interviews and correspondence which issued in her retirement to the convent of the Carmelites. If, in the case of Madame de Montespan, his actions are more open to misconstruction, yet further investigation tends towards his acquittal of the charges advanced by various historians.

Appointed in 1681 to the bishopric of Meaux, Bossuet had scarcely been installed when he was summoned to take part in the memorable assembly of the French clergy with which his name will always be associated. This council was convoked by royal edict, at the instance of the clergy themselves, for the purpose of finding a way out of the conflict, yearly growing fiercer, between Louis and Rome. The strife arose about the *regalia*, or claim of the Crown to administer the affairs of a vacant see until such time as its new occupant should take the oath of fidelity. But in the course of its discussions the council was agitated by questions far wider than that in which it took its rise, and embracing eventually the whole subject of the extent and limits of Papal authority. Bossuet preached the opening sermon. He gave fearless utterance to his cherished opinions. Referring to the aggressive disposition of the Papacy he declared—"Ocean itself, immense though it is, has its limits, and to break through at its own caprice would be to lay desolate the world." At the same time, seeing the heated state of the public mind, he counselled moderation, occupying a middle place between Ultramontanists and ultra-Gallicans, and was even opposed to any formal declaration of the Gallican position. Being overruled in this chiefly through the influence of Harlay, archbishop of Paris, he next directed his efforts towards issuing the assembly's decision in the most temperate and conciliatory form. He was himself appointed to draw it up, and there resulted the famous four articles which were in substance these:—I. The civil authority is not subject to the ecclesiastical in temporal things; II. As decreed by the Council of Constance, a general council is superior to the Pope; III. The exercise of the apostolic power ought to be tempered by the usage of particular churches; IV. Except with the consent of the church the judgment of the Pope is not unalterable in matters of faith. Being virulently attacked, these propositions were defended by Bossuet in his great *Defense de la doctrine du clergé de France*, which, however, was not printed until 1735.

Bossuet applauded the shameful revocation of the Edict of Nantes (1685), but his English biographer reminds us that, stern as was his character, he did his utmost to secure to Protestants as much liberty as was possible under the existing law; and, further, that no military execution took place during his episcopate at Meaux.

In 1688 there appeared *L'Histoire des Variations des Églises Protestantes*, a review and analysis, in fifteen books, of the confessions of faith emitted by Protestant churches during the epoch of the Reformation, in which Bossuet aims at demonstrating their incoherency and self-contradiction, even on cardinal points, as contrasted with the doctrinal stability of Rome. Forcible and learned as it undoubtedly is, this work is grievously lacking in candour, and in the paramount love of truth, the treatment of Luther and his writings being especially unscrupulous and vindictive. Indeed, from first to last, it is executed in the spirit less of an upright judge than of an unprincipled partisan. These less attractive features of Bossuet's character, over which one would gladly throw the veil, became still more prominent when in 1689 there broke out the bitter quarrel on the subject of "Quietism," the melancholy and fluctuating history of which may be best embraced

under that of Fénélon. Bossuet, by his attitude, alike unjust and ungenerous, has left an indelible stain upon his otherwise brilliant reputation, while the man for whose condemnation he resorted to violence and intrigue conducted himself with the meekness and charity of a saint. Attacked by a painful disorder, of which the premonitory symptoms appeared in 1696, the venerable prelate lingered on until the 12th of April 1704, when he died at Paris in his 77th year, amid the tokens of universal regret.

Of unrivalled eloquence and consummate learning, an intrepid controversialist and defender of the faith, as well as the most conscientious and diligent of bishops, he will probably be remembered longest as the champion of the ancient rights and liberties of the Gallican Church, and the representative of a phase of catholicism which the Vatican council has for ever banished from within the Roman pale.

The best edition of Bossuet's works is that of Lachat in thirty-one vols., Paris (Vives). See also *Life of Bossuet*, by Cardinal de Bossuet; *Studies of his Life*, by Floquet; and the *Memoirs* of the Abbé le Dieu. There is a full and admirable English *Life of Bossuet*, by the author of the *Life of St Francis de Sales*, 1874. For Brougham's estimate of Bossuet as an orator, which is very depreciatory, see his *Works*, iii. 262–269. For a criticism of *L'Histoire Universelle* see Flint's *Philosophy of History*. (A. B. C.)

BOSTON, a parliamentary and municipal borough and seaport town of England, in the county of Lincoln and wapentake of Skirbeck. It is situated in a rich agricultural district on the Witham, six miles from the sea, and thirty miles S.E. of Lincoln on the Great Northern Railway, in 52° 59' N. lat. and 0° 2' E. long.

Boston is by some supposed to have been a Roman station in the province of *Flavia Cæsariensis*, but of this sufficient evidence does not seem to exist. According to the Saxon Chronicle, St Botolph, the patron of sailors, founded a monastery at Icanhoe in 654, which was destroyed by the Danes in 870. From this Boston is said to have taken its name (Botolph's town). It became a place of considerable commercial importance after the Norman Conquest, and, in 1204, when the *quinzième* tax was imposed on the ports of England, that of Boston amounted to £780, and was exceeded only by that of London, which was £836. A great annual fair was held in the town at this period. By 27th Edward III. it was made a staple for wool, woolfells, leather, and lead. Its prosperity about this time induced merchants from the Hanseatic and other Continental commercial cities to settle here; a century later, however, these foreigners were obliged to leave, in consequence of a quarrel with the townsmen. From this time it rapidly declined. The dissolution of the monasteries by Henry VIII. injured the town, though compensation was in some degree made by granting it a charter of incorporation; and Philip and Mary endowed it with upwards of 500 acres of land. It afterwards suffered from the plague and from inundations, to which its low situation rendered it particularly liable. It was for some time the headquarters of Cromwell's army.

Arms of Boston.

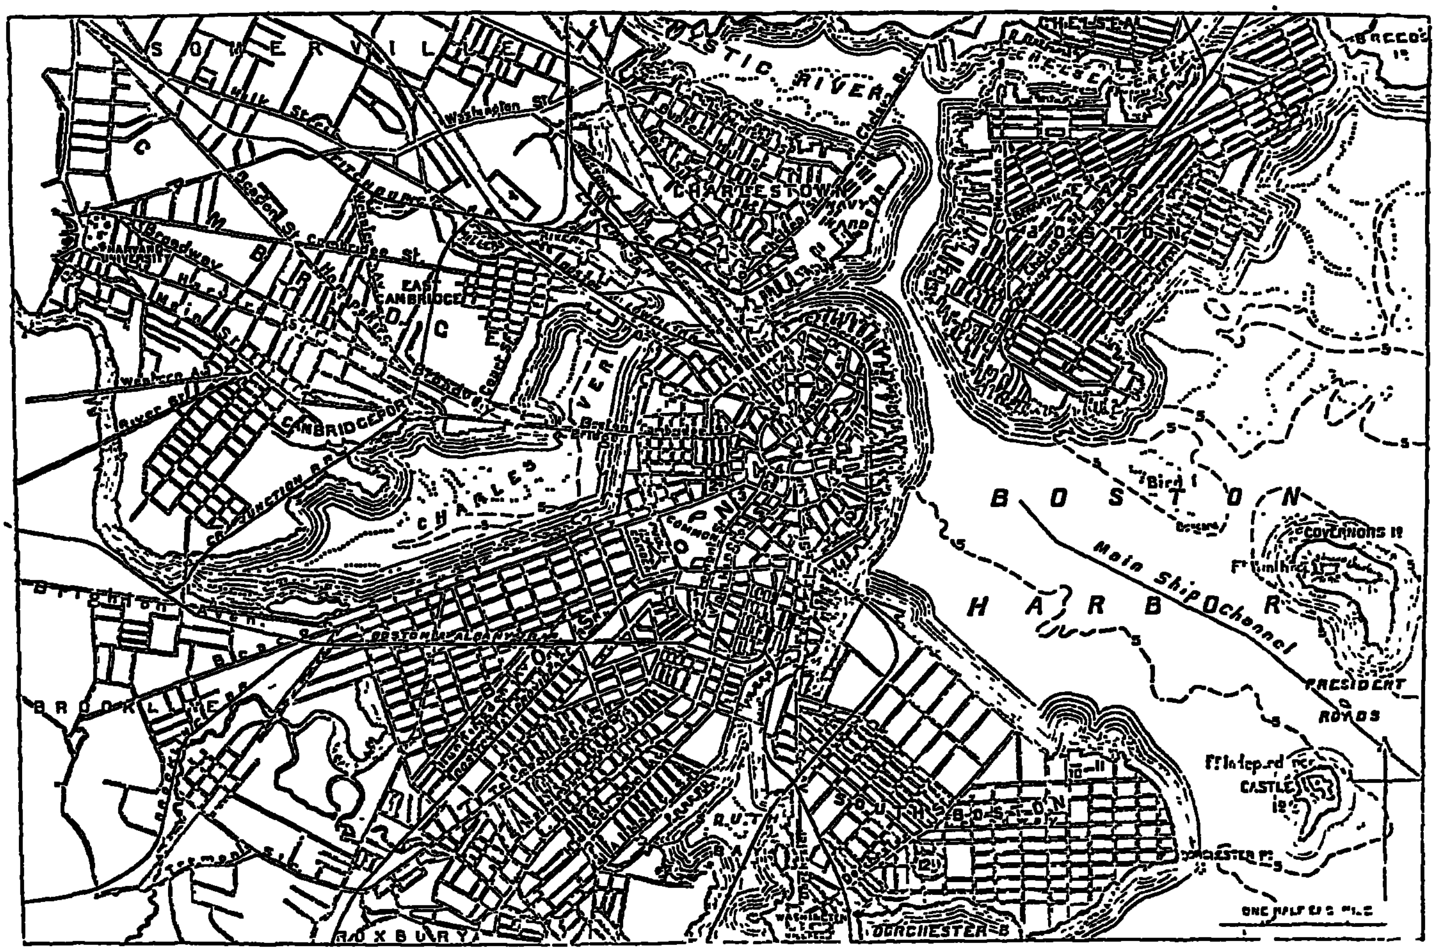
Boston is well built, paved, and lighted. It is divided into two nearly equal parts by the Witham, here crossed by an elegant iron bridge of one arch, 86 feet in span. At one time the supply of water was very deficient; but, in virtue of an Act passed in 1847, there is now a plentiful supply conveyed by pipes from a distance of twelve miles. The principal building is the parish church of St Botolph, founded in 1309, and partly restored in 1857 at the expense of the inhabitants of Boston in America, in memory of their connection with the English city. It is one of the largest churches without aisles in the kingdom, being 290 feet by 98 within the walls. The tower, 290 feet in height, resembles that of Antwerp cathedral, and is crowned by a beautiful octagonal lantern, forming a landmark seen forty miles off. A chapel of ease was erected in 1822. There is a free grammar school, founded in 1554, a charity school for the sons of poor freemen, a blue-coat, national, and other schools. There is also a dispensary, a town-hall, a market-house, a custom-house, assembly rooms, a theatre, a borough gaol, a house of correction, a union poor-house, Vauxhall gardens, a mechanics' institution, public baths, subscription libraries, an athenæum, and a freemason's hall, built in imitation of Egyptian architecture. The manufactures consist chiefly of sail-cloth, canvas, sacking, ropes, beer, leather, hats, and bricks. There are also iron and brass foundries, and ship-yards, with patent slips, where vessels of 200 tons are built.

From neglect to clear the river, it became so obstructed that in 1750 a sloop of 40 or 50 tons could with difficulty come up to the town at spring tides. Since that period great improvements have been made, and vessels of 300 tons are enabled to unload in the town. The imports are chiefly timber, pitch, tar, and hemp from the Baltic, and coal and manufactures coastwise; the exports, wool, wood, corn, and other agricultural produce. The total value of the former was in 1873, £200,825, and of the latter £86,571. By means of the river and the canals connected therewith, Boston has navigable communication with Lincoln, Gainsborough, Nottingham, and Derby. The East Lincolnshire Railway connects it with Louth, Grimsby, and other towns in the north, and the Great Northern with Peterborough and the south; another line extends to Lincoln. It has returned two members to parliament since the reign of Edward IV. The title of Baron of Boston is borne by the Irby family. In 1871 the population within the parliamentary boundaries was 18,279; within the municipality, 14,526.

BOSTON, the capital of the State of Massachusetts, in Suffolk County, and the second city in commerce, wealth, banking capital, and valuation in the United States of North America. It lies at the bottom of Massachusetts Bay, and is one of many pear-shaped peninsulas formerly attached to the mainland only by narrow marshy necks, which fringed the shores of the bay. The Charles River, once more than double its present width, divides it from the similar promontory of Charlestown (the site of the battle of Bunker Hill), on the other side of which the Mystic River, uniting with the Charles, flows into the harbour. The latest determination gives the latitude of Boston 42° 21' 27·6" N., and the longitude 5° 59' 18"E. from Washington and 71° 3' 30" W. from Greenwich. When it is noon in Boston it is 4 o'clock 44 minutes and 14 seconds at Greenwich, and 36 minutes past 11 at Washington, which is distant by railroad 450 miles.

The Indian name of the peninsula was "Shawmut," meaning "living fountains." When Governor John Winthrop, with his company, came over from England with the king's charter, to establish a government under it in the bay, they reached Charlestown, as a temporary settlement, on June 17, 1630. Looking across the Charles, the Indian Shawmut presented to the eye an elevation nearly in its centre, with three distinct summit peaks, the remnants of the only one of which now remaining constitute the present Beacon Hill, so called from its ancient use as a signal warning station. These triple summits led to the substitution of the name "Trimountaine," or "Tremont," as the English designation of the whole peninsula—a favourite title perpetuated in the name of a central street,

a hotel, a theatre, a bank, a lecture-hall, &c. A single lonely white man, the Rev. William Blaxton, a clergyman of the English Church, was then living, with house, orchard, and garden on the slope of the central hill, supposed to have come over in 1623, one of several isolated settlers on the promontories and islands of the bay, called "the old planters." He invited Winthrop's company to cross the river and build their cabins on his side, because of the purer and more abundant water-springs. On the records of the company we read, that at a court held in Charlestown, September 17 (N.S.), 1630, "It is ordered that Trimountaine shall be called Boston." This has consequently been the date assumed for the foundation of what is now the present city, and the second centennial of which was commemorated by public civic services, an oration by Josiah Quincy, a former mayor, then president of Harvard University, and a poem by the banker-poet, Charles Sprague. It is not probable that the peninsula was occupied till a month later. Blaxton, not finding the new-comers congenial associates, sold out his rights to them in 1634, and moved elsewhere. It has often been said, and has been widely accepted, that Boston received its name in compliment to the second minister of its first church, the Rev. John Cotton, formerly vicar of St Botolph's, borough of Boston, Lincolnshire, England. This was not the case. The Rev. John Wilson, of King's College, Cambridge, and of Sudbury, in Suffolk, England, came in Winthrop's company, and was first pastor of the



Ground-Plan of the City of Boston.

church. Cotton did not arrive till September 4, 1633, three years after the name Boston had been adopted. Undoubtedly the name was chosen in compliment to the much honoured Mr Isaac Johnson, one of the foremost in the enterprise, who with his wife, the Lady Arbella, daughter of the Earl of Lincoln, came with Winthrop in a vessel bearing her name. Johnson was from the English Boston, as were also his associates, Atherton Hough, who had been mayor of the borough, and Thomas Leverett, "ruling elder" of the church, who had been an alderman.

Some graceful courtesies have been exchanged in recent years between the two cities. The English Boston sent over a copy of her charter, framed in wood from St Botolph's church, and this now hangs in the city hall of the Massachusetts capital; and some descendants of John Cotton, with members of his American Church, through one of their number, Edward Everett, then American minister at the Court of St James's, united in a generous subscription to restore a chapel in St Botolph's, and to erect a monumental tablet in it to the revered teacher.

The sea-girt peninsula seems to have attracted the choice of the colonists as a place of settlement, because of its facilities for commerce and for defence. Its aboriginal occupants had previously been devasted by a plague, leaving it vacant. Some fifty years afterwards the settlers satisfied the claims of an Indian sachem, representing that his grandfather had been its proprietor. Had these settlers contemplated the enormous outlay of labour, skill, and money, which their posterity would have to expend upon the original site to make it habitable and commodious, they might have planted themselves elsewhere. There was neither wood nor meadow on the peninsula; but it might be defended from the Indians and wolves, and as one early visitor vainly imagined, from "moskitoes." The surface was very abrupt, irregular, hilly, and undulating, deeply indented by coves, and surrounded by salt-marshes left oozy by the ebbing tides, and separating the shores from the river channels. The peninsula contained less than 1000 acres, and the narrow neck, which joined it to the main, was often swept by spray and water. The

widening of Charles River near its mouth gored deeply into the northern side of the peninsula, almost dividing it, and the waters were soon turned to account for a mill-pond. This was filled up by earth from the hills in 1807, adding more than 50 acres to the territory. Another broad cove on the southern side was filled in 1837, adding 77 acres more. The Back Bay, so called, and all the flats on both sides of the original neck, have since been reclaimed for the various uses of a public garden, and squares, streets, dwellings, churches, schools, hotels, manufactories, &c., constituting, in fact, a new city with many costly and elegant structures, on what was originally the narrowest and most disagreeable, but is now the fairest and widest, portion of the primitive site. But whole forests from the State of Maine, and vast quarries of granite, and hills of country gravel, have been put to service in fringing water margins, constructing the wharves, piers, and causeways, redeeming the flats, and furnishing piling and solid foundations for the stately edifices, private houses, halls, churches, and railroad stations, principally between Charles River and the old Dorchester flats. From the first settlement, however, the ownership and occupancy of land by the citizens were not confined to the soil of the peninsula. The land needed for grazing, farming, and wood, on neighbouring promontories and islands was soon placed under the jurisdiction of Boston, for its "inlargement." Portions of territory, thus added, were from time to time severed, and have since been re-annexed. Noddle's Island, now East Boston, was "layd to Boston" in 1637. It then contained 660 acres, with several hundreds more of flats and marsh, since reclaimed. It has a wharf, 1000 feet in length, for the English and Canadian steamers. Dorchester Neck and Point, containing 560 acres, were annexed as South Boston in 1804, and the neighbouring Washington Village in 1855. The city of Roxbury was annexed in 1868; the town of Dorchester in 1870; the city of Charlestown, and the towns of Brighton and West Roxbury, in 1874. The 900 acres of the original peninsula have been doubled on its own area; while the present area of the city's jurisdiction covers 22,472 acres. The whole length of the original peninsula, from Roxbury line to Winnisimmet Ferry, was two miles and a little more than three quarters; its greatest breadth was 1 mile and 139 yards. The reclaimed territory is raised to a uniform level, sufficiently high to secure it against freshets, and is well drained. While the original site still preserves to a large extent its irregularity of surface, and its undulations, some of its former steep eminences have been reduced or wholly removed. The highest eminence in the old territory is about 110 feet above the sea-level. This work of levelling, grading, and reclaiming has been done at vast expense. But greater has been the expense of widening and straightening the narrow and crooked highways, streets, thoroughfares, and lanes of the first settlers, which are traditionally said to have been made by the cattle on their way to and from their pastures. This, next to the water-works, has been the occasion of the most considerable increase of the debt incurred by the city, somewhat relieved by assessments for betterment on abutting proprietors. It is believed that there has been a larger outlay of labour, material, and money, in reducing, levelling, and reclaiming territory, and in straightening and widening thoroughfares in Boston, than has been expended for the same purposes in all the other chief cities of the United States together. The broad watercourses around Boston are now spanned by causeways and bridges,—East Boston only, that the harbour may be opened to the navy-yard, being reached by a ferry. The first bridge over Charles River, that to Charlestown, was opened in 1786; the West Boston bridge, to Cambridge, in 1793; the Western Avenue, a solid causeway to Brookline, 7000 feet long, in 1821. Boston has now to maintain sixteen bridges. Most of the railroads also have their bridges. Six of the islands in Boston harbour are the property of the city, and three more of them have been ceded to the United States for fortifications. The harbour islands, including rocks and shoals, are very numerous, rendering the navigation through the two channels very difficult and easily guarded. But the harbour, when reached, is very secure. It is nearly 14 miles long, and 8 miles wide, giving nearly 60 square miles of anchorage. These islands were for the most part heavily wooded when first occupied, and some of them were profitably used for grazing and pasturage. Since they have been stripped of their primitive growth for fuel and building material, it has been found impracticable to reclothe them with trees, on account of the roughness of the sea-air. The washing of the soil from the bluffs of many of them, to the great injury of the harbour, has involved large expense in the erection of sea-walls. The first settlers constructed rude defences, frequently repaired and extended, on Castle Island, $2\frac{1}{4}$ miles from Boston. More formidable works were raised here by an English engineer in 1701–3. The United States Government has constructed elaborate fortifications on this site, now called Fort Independence, which, with Forts Winthrop and Warren, on neighbouring islands, offer formidable harbour defences. The first lighthouse was erected in the harbour, on Beacon Island, $8\frac{1}{4}$ miles from the town, near the Great Brewster, in 1716. This was destroyed during the Revolutionary War, re-erected in 1783, ceded to the United States in 1790, refitted in 1856 and 1860, with a tower 98 feet high, fog-horn, bell, &c., and is now called the Outer Light. An inner lighthouse was established on Long Island Head in 1819, refitted in 1855. On the long spit, at the western extremity of the Little Brewster, stands the Bug or Spit Light, erected in 1856.

It is remarkable, considering the leading and conspicuous character which has always attached to Boston from the first English settlement of the country, that it should have remained for nearly two centuries under the simple form and administration of a town government, the same as that of the smallest interior hamlets. Such a government, by all the citizens assembled in "town meeting" to dispose all their affairs, was, however, found favourable to the development and prosperity of the community. Here was trained a homogeneous population under peculiar institutions. Wealth slowly but steadily increased, through the whale and cod fisheries, the fur-trade, the sale of lumber and pitch, and a commerce largely with the West Indies and elsewhere,—though much impeded by the restrictions of the English navigation laws. Heavy exactions and drawbacks were found in the Indian and in the French colonial wars. Here began opposition to the measures of the British ministry, for oppressing and taxing the colonies. The Stamp Act, passed in 1765, was repealed in 1766. The Tea Act, passed in 1773, was defied by the emptying of three cargoes of tea into the harbour, December 16 of the same year, by a party in the guise of "Mohawk Indians." The port was closed by a British fleet, June 1, 1774. The British army evacuated Boston March 17, 1776, after having been beleaguered in it nearly a year. The constitution of the State was adopted here in 1780, midway in the war.

Boston received a city charter in 1822. Its Government is composed of a mayor, twelve aldermen, and a common council of seventy-two members, three from each of its twenty-four wards, annually elected by the citizens. There are commissioners for fire, water, health, and various other departments. There is a board of twelve overseers of the poor, with a commodious central building, connected

with twelve charitable organizations, with which the board acts in concert. The board holds charity trust funds amounting to $312,183, it expended in 1874 $101,591, and relieved 304 beneficiaries on its trust funds, and 9762 other persons.

Population, Valuation, &c.—The population of Boston, in 1708, was about 12,000; in 1719, about 18,000; in 1780, about 23,000; in 1800, 25,000; in 1850, 139,000; and, with Roxbury and Dorchester, in 1873, was 308,875. Charlestown brought with it 32,040; West Roxbury, 10,361; and Brighton, 5978. The total, in 1875, must be nearly 360,000. The valuation of the city in May 1875 was $554,200,150 of real estate, and $244,554,900 of personal property,—total, $798,755,050. The value of the corporate public property is $30,787,292. The net city debt is $27,294,208. The number of public paupers, including insane, is 689; of criminals, 1495. There are fifty-eight banks of deposit and discount in the city, the capital of which is $52,900,000, and the circulation $27,074,396. The number of savings-banks is twenty-one, with deposits of $73,322,368·56. Of fire and marine insurance companies, stock and mutual, there are thirty, with four new ones in formation, besides life insurance companies and those against accidents and for specific forms of property. The annual sale of merchandise in the city is estimated at $1,000,000,000.

Commerce.—Boston has commercial relations with every part of the globe. In 1874 the gold value of its foreign imports was $49,522,547; of its exports of foreign merchandise, $2,084,257; and of its domestic merchandise, in currency, $27,035,169. There arrived 167 American vessels from foreign ports, with a tonnage of 234,587 and 6324 men; of foreign vessels from foreign ports 1849, with a tonnage 484,448 and 18,486 men. There cleared for foreign ports, 598 American vessels, with 254,347 tons and 6606 men; and 1882 foreign vessels, with 472,941 tons and 17,995 men. The total tonnage of Boston, registered and enrolled, on December 31, 1874, was 331,266. Its commerce is slowly recovering from the effects of the war of secession.

Great Fires.—The buildings of Boston having from the first been largely of wood,—the use of which material for that purpose is now under severe restrictions,—and closely compacted, the old town suffered from frequent and disastrous conflagrations, several of which were successively described as "The Great Fire." There had been ten of these disasters, severe under the then existing circumstances, before the year 1698. In 1711, the town-house and a meeting-house, both of brick, and a hundred dwellings were destroyed. In 1760 a conflagration consumed 349 dwellings, stores, and shops, and rendered more than 1000 people homeless. But these and all subsequent ones were eclipsed in their devastation by the disaster of November 9–10, 1872, in which hundreds of costly warehouses filled with goods, with banks, offices, churches, &c., were destroyed, though all of brick or granite, involving a loss of over $80,000,000. It is an evidence of the energy and resources of the citizens, that in a little more than two years after the catastrophe, the whole "burnt district," with widened and improved thoroughfares, was covered with solid, substantial, and palatial edifices combining all the safeguards, improvements, and conveniences of modern skill. At least as large an amount has been expended on this restoration as was lost in the ruin. The fire department has been made more efficient under the control of three commissioners. There are now in the city twenty-nine steam fire-engines and a fire-boat in the harbour, eleven hook and ladder companies, sixteen horse-hose companies, a protective department, an insurance brigade, with waggons, &c., an alarm telegraph, and a system of signal boxes.

Water Supply.—Though the first white settlers were drawn to Boston by its pure and abundant springs, the want of water resources was long felt till efficient measures were taken for a supply. The southern portion of the town was supplied at the beginning of this century by an aqueduct from Jamaica Pond in Roxbury. The works already constructed and still in progress fully meet the present and prospective demands. The waters from Cochituate Lake and its tributaries, from twenty to thirty miles from the city, flowed into it by gravitation, October 25, 1848. The storage reservoirs and the works have cost up to May 1875, $10,786,739. The length of the conduit of brick is $14\frac{1}{8}$ miles, and of supply pipes of iron $262\frac{1}{8}$ miles. The annexation of Charlestown brought with it the waters of Mystic Lake, the works for which had cost $1,147,902, with $1\frac{1}{2}$ miles of brick conduit, and 127 miles of pipe, pumping engines, and reservoir.

The *public schools* of the city are organized and supervised under the statutes of the State which make provision for free education by some compulsory enactments, subject to such special regulations as may be enjoined by the Legislature. The Legislature of 1875, by an Act (chapter 241), introduced a change in the composition and functions of the school committee. Henceforward this board is to consist of twenty-four members, chosen by the citizens on general ticket, to be disposed in three sections of eight members each. After the close of the first year from the first election, eight members are to retire, and eight new members are to be elected, to serve for three years, all without compensation. The board is to elect and fix the compensation of a secretary, an auditing clerk, and other necessary subordinate officers, and also of a superintendent of schools, and a board of not more than six supervisors. The mayor is to be, *ex officio*, chairman of the general board, to which no other member of the city government can belong, and which shall have the whole management of the schools, choosing and fixing the compensation of all teachers, janitors, &c., but needing the authority of the city council before incurring an expense exceeding $1000 for the purchase of land, or the erection or alteration of a building. Boston has now 9 high schools, 49 grammar-schools, 416 primary schools, 25 evening schools and industrial, licensed minors', deaf-mute, and kindergarten schools,—total, 499. The number of teachers employed is 1289; of scholars, 53,391. Cost of maintenance for the year ending May 1, 1875, $1,724,373·61. In the old city there is a Latin, English high, girls' high, and normal school; and in each of the municipalities that have been annexed there is a high school, where classical education is furnished.

The *public buildings* of Boston are very numerous, embracing those of the United States Government, the State, the county, and the city. Most of them have been built within a few years, and are substantial and commodious, but, owing to the constant expansion and growth of the city, each of them in turn becomes contracted, and needs enlargement or a substitute. The buildings connected with each of the railroad stations have been reconstructed for extension three or four times. The largest group of edifices and works is that of the United States navy-yard, with docks, manufactories, foundries, machine shops, ordnance stores, rope-walks, furnaces, casting pits, timber sheds, ordnance parks, ship-houses, &c. The half of a very elaborate and costly edifice, the corner-stone of which was laid by President Grant, is now (1875) completed and in use for the United States post-office and sub-treasury. The other half, now in progress, will accommodate the United States courts. There is also a custom-house, with bonded warehouses, and the United States court-house.

The State House, for the business of the Legislature of the commonwealth, was built in 1798, and has been recently greatly extended. It stands on the highest land in the city,—what remains of the old *Trimountaine* summits,—and has a gilded dome, fountains, and statues on its lawn, with statues, busts, paintings, and trophies within. The edifice looks nobly down upon the "Common," so dear to the citizens of Boston. This park came with the original purchase from Mr Blaxton, and encloses 48 acres, with malls all round it, a pond, a fountain, a soldiers' monument, a deer park, and about 1300 trees. An Act of the Legislature of 1875 protects it from being encroached upon in any way by the municipal authorities without a vote of the majority of the citizens. To the State also belong a court-house and some of the newly reclaimed territory on the South Bay. To the county of Suffolk belong a jail, and court-houses, municipal and probate. The State prison is in Charlestown district.

To the city, besides the school-houses,—which bear the names of honoured citizens for many generations, and of ex-mayors,—belong a large number of structures and appliances:—the Old State House, so called, built for the British authorities in 1712,—the oldest public building now standing in the city, Christ Church, dedicated in 1723, coming next to it; Faneuil Hall, famous for its patriotic oratory, originally the gift of Peter Faneuil in 1743, used for "town meetings," and enlarged in 1806; extensive market-houses; the City Hall; the Public Library; bath-houses; engine-houses and armories; the Public Garden on the new territory, highly ornamented, enclosing more than 24 acres, with a pond; city stables, &c.

Statues in public places:—in bronze, a fine equestrian statue of Washington, and those of Dr Franklin,—born in Boston, January 17, 1706,—of Daniel Webster, Horace Mann, and Edward Everett; of marble or granite, Washington, Alexander Hamilton, Governor Andrew, Columbus, Aristides, soldiers in the war of secession, and the monument commemorating the introduction of the use of ether as an anæsthetic, first applied in the Massachusetts General Hospital, Boston.

Boston is fringed with substantial wharves on all its water margins, for the most part covered with massive warehouses. Horse railroads, or tramways, make easy connections within its own limits, and with the suburbs. Steam roads open communication with the whole continent, in every landward direction. Successive experiments have been tried with the various materials and methods for paving the streets, and constructing side-walks. The streets of the town were first named in 1708. The first map of the town, that of Bonner, was made in 1722. Overseers of the poor were first chosen in 1691. The superintendent of lamps has charge of 7664 gas, and 976 fluid, burners. The cost of gas to the city, for 1874, was $275,064·35. There are seventeen police-station houses and lock-ups; the expense of that department was $683,892·78; of the health department, $446,877·08; of the fire department, $671,511·13; of the City Hospital, $111,198·31; of penal and pauper institutions, $405,903·40. The cost of street widenings and extensions from 1822 to 1874 was $21,739,983·13; and in 1873–74, $6,403,413·76, reduced by "betterments," $283,697·50; tax assessed in 1874, $9,022,187·17 The revenue of the city was $23,633,874·06. There had been in the town and original city eleven burial-places. Mount Auburn Cemetery in Cambridge, five miles distant, enclosing 125 acres, was put to use in 1831. There have been more than 19,000 interments in it. Five other suburban cemeteries are now provided, and interments in the city are prohibited.

The Public Library, as an institution of the city, was fostered by an enterprise initiated by M. Vattemare, in securing a gift of books from the city of Paris, in 1843. Acts of the Legislature, renewed and extended from 1848 to 1857, aided by the efforts of individual citizens and meetings of committees, with free and conditional gifts of money and of books, kept the object steadily in view. In 1852 Mr Joshua Bates, born in Massachusetts, then of the firm of the Messrs Baring, of London, made a gift to the city for the purpose of a library, of $50,000, subsequently adding various donations of books. The main hall of the library building bears his name, in commemoration of his munificence. The present spacious and solid structure, which, however, already needs a second enlargement, was inaugurated for its uses, on January 1, 1858, with an address by Edward Everett. It cost, with the land, $365,000. Large donations of money and of private libraries have since accrued from living benefactors, and by bequests. The names of Ex-Mayor Bigelow, of Abbot Lawrence, and Jonathan Phillips deserve mention for their pecuniary gifts; while the libraries of Theodore Parker, Edward Everett, and George Ticknor have furnished most valuable acquisitions. Here is deposited the Prince Library, belonging to the Old South Religious Society. The unique and rich collection, known as the Barton Library, of 12,000 volumes, including the magnificent Shakspearian treasures, was obtained in 1873. The edifice has been once enlarged, with efforts to render it fireproof, and additional ground has been purchased at a cost of $70,000. The expense of its maintenance and care, in 1874, was $135,000. There are employed in it 103 persons. The number of volumes is about 280,000, besides pamphlets, MSS., and valuable collections of engravings, including the Tosti, so called. Branch libraries are established for the convenience of the citizens, in South and East Boston, Dorchester, Roxbury, Brighton, and Charlestown; and a system of other local deliveries has been initiated.

Of *churches* and places of worship in Boston, there are 163 for Protestants, 26 for Roman Catholics, and 3 Jewish synagogues. The Roman Catholics have a cathedral which will seat more than 4000. The Unitarians have the largest number of Protestant churches. There are 112 public halls, which serve very miscellaneous uses of worship, debate, lecturing, society meetings, and amusement.

Literary, learned, scientific, benevolent, and secret societies, represented by their own edifices, halls, libraries, and collections, are very numerous, and well sustained. Among these may be mentioned the American Academy of Arts and Sciences; the Massachusetts Historical Society; the Boston Athenæum, with a very extensive library, paintings, and statuary; the New England Historic Genealogical Society; the Masonic Temple; the Odd Fellows' Hall; the Mechanics' Association; the Mercantile Library Association; the Massachusetts Institute of Technology; the Boston College (Roman Catholic); the Boston University (Methodist); Young Men's Christian Union; Young Men's Christian Association, with a sectarian condition; Young Women's Christian Association; the Natural History Society; the Horticultural Society; the Marine Society; the Boston Library Society; the Music Hall, with its great organ; the Harvard Medical School, and Warren Museum; the State Library; the Law Library; the General Theological Library; the Art Museum, &c. There are four theatres in the city,—the Boston, the Globe, the Howard, and the Museum.

Hospitals, asylums, and refuges, chiefly founded and sustained by private benevolence, and generously administered, provide, for the most part gratuitously, for the various ills and maladies of humanity. Of these, besides the City Hospital, may be mentioned the Massachusetts General Hospital, with its branch for the insane, the

M'Lean Asylum, in a suburb; the Orphan Asylum; the Perkins Institution for the Blind; the Eye and Ear Infirmary; the Consumptives' Home; the Carney Hospital; the Homœopathic Hospital; the School for Idiotic and Feeble-minded; the Lying-in Hospital; the Temporary, Washingtonian, and Appleton Homes; Hospitals for Women, Children, and Infants; Homes for Aged Men, for Aged Women and for Coloured Women, for Little Wanderers; a Children's Mission; House of the Angel Guardian; Commissioners of Foreign Missions, &c. The city institutions for paupers, the insane, and criminals, are in South Boston and on Deer Island.

Ninety years after the settlement of the town of Boston, Daniel Neal, of London, wrote a description of it, returning from his visit. In this he says: "The conversation in this town is as polite as in most of the cities and towns in England, many of their merchants having travelled into Europe, and those that stay at home having the advantage of a free conversation with travellers; so that a gentleman from London would almost think himself at home at Boston, when he observes the numbers of people, their houses, their furniture, their tables, their dress, and conversation, which perhaps is as splendid and showy as that of the most considerable tradesmen in London." Though in the succession of visitors from abroad, particularly from England, who have followed Mr Neal, there have been a few who have found matter for satire and depreciatory criticism in their accounts of Boston, of its citizens, their habits, &c., the great majority of its foreign guests, especially if their own manners and errands have recommended them, have written in a similar strain. They have found there much to learn and enjoy, and to remember with pleasure. Cultivated Englishmen, particularly those who have visited Boston in recent years to obtain or to impart information, have found themselves at home there. The supposed conceit of its citizens over their own distinctive qualities or advantages has led to some pleasant banter from at home and abroad in characterizing the city as the "Athens of America" or "The Hub of the Universe."

The development, growth, and increased population of the city, under the liberal social influences, and the changes of opinion and habit, which in no part of the world are more marked and active than here, have, of course, wholly displaced the original homogeneousness of its people, and the peculiarly Puritan character of the tone and customs of life. Its large foreign population make, in traditions, habits, social relations, and religion, a nation within a nation. The unfamiliar names which appear on the signs of shops and dwellings, the relaxed usages as regards the observance of Sunday, and the indulgence in amusements, large personal freedom, &c., have made Boston, substantially, a cosmopolitan city. Those now living remember when a person who ventured to smoke a cigar or a pipe in the street would have fallen into the hands of a constable. When the traffic in the streets is annually obstructed by an elaborate procession, mounted and on foot, on "St Patrick's Day," and when a cardinal, with other officials from the court of Rome, comes hither to consecrate an archbishop in a cathedral, it is difficult to recall the virgin promontory and the English exiles with which this notice began. (G. E. E.)

BOSTON, Thomas, a popular and learned Scottish divine, born at Dunse, May 17, 1676. He was educated at Edinburgh, and in 1699 became minister of the parish of Simprin, from which he was translated in 1707 to Ettrick. It was by his recommendation that Hog of Carnock reprinted in 1718 the famous *Marrow of Modern Divinity*, which excited such a fierce controversy in the Scottish church. He also distinguished himself by being the only member of Assembly who entered a protest against the sentence passed on Professor Simson as being too slight a censure. He died May 20, 1732. His writings were numerous; but he is best known by his *Fourfold State*, the *Crook in the Lot*, and his *Body of Divinity*, works much esteemed by Presbyterians, and which long exercised a powerful influence over the minds of the Scottish peasantry. He left *Memoirs of his own Life and Times*, published in 1776. An edition of his works in 12 volumes appeared in 1849, *ff.*

BOSWELL, James, the biographer of Johnson, was born at Edinburgh on the 29th October 1740. His father was one of the lords of Session, or judges of the supreme court in Scotland, and took his title, Lord Auchinleck, from the name of his property in Ayrshire. The family was of old and honourable descent, a fact of which both father and son were not only proud but vain. James, the eldest son, was educated at Edinburgh and Glasgow Universities, and during his student days contracted a close and life-long friendship with William Johnson Temple, afterwards vicar of St Gluvias and rector of Mamhead. His unrestrained correspondence with Temple, extending with occasional breaks from 1758 to the last year of his life, affords us the best materials for a knowledge of his career and an estimate of his character. At the age of eighteen he was busily engaged in the study of the law at Edinburgh, not entirely in accordance with his own inclination, but in obedience to the desire of his father. Already, however, he had begun to take a pride in being associated with men of distinction, and tells his friend, with some exultation, that he had accompanied Sir David Dalrymple (afterward Lord Hailes) on the Northern Circuit, and had kept a journal of what was said by the great man on the way. Some other peculiarities of his character also became manifest even at this early period of his life. He was evidently unsettled and unstable, "constitutionally unfit," as he afterwards said, "for any employment;" he disliked the Scottish style of life, and longed for the elegance, refinement, and liberality of London society. In 1760 this wish was so far gratified; he tasted some of the delights of the capital, and indulged in magnificent dreams of entering the Guards and spending his time about the court. Such a fancy, however, came to nothing; for as he has narrated with some pride, the duke of Argyll told his father that "this boy must not be shot at for three and sixpence a day." A military life, indeed, would hardly have suited him, for, as he frankly confesses, his personal courage was but small.

Boswell's tastes were always literary; he had contributed some slight things to the current magazines; and in 1762 he published a rather humorous little poem, *The Cub at Newmarket*. In the following year appeared a collection of *Letters between the Hon. Andrew Erskine and James Boswell, Esq.*, which the vanity of the youthful authors induced them to think would be received with pleasure and profit by the world. The only prominent characteristic of these epistles is an overstrained attempt at liveliness and wit.

On Monday, 16th May 1763, Boswell, then on a second visit to London, had the supreme happiness to make the acquaintance of the object of his almost idolatrous admiration,—Dr Johnson. Their first interview in the back parlour of Mr Davies's shop in Russell Street was characteristic of both; the calm strength and ponderous wit of the one, the fluttering folly and childish servility of the other, are portrayed to the life in Boswell's own narrative. Few things are more singular than the intimacy which sprang up between two men so differently constituted. Boswell might indeed congratulate himself that he had something about him that interested most people at first sight in his favour. He was then about to proceed to Utrecht in order

to prosecute his studies; and the great Dr Johnson actually accompanied him to Harwich and saw him off, with many protestations of affection.

At Utrecht Boswell was as unsettled and dissipated as before. He had a fair allowance from his father—£240 a year; but he was determined "not to be straitened nor to encourage the least narrowness of disposition as to saving money." To what extent this virtuous resolution was carried out is unknown; but after leaving the university, he determined, sorely against his father's inclination, to prolong his residence abroad. He travelled through various parts of the Continent, visited Voltaire and Rousseau, and was finally attracted to Corsica, where he speedily attached himself to and became the intimate friend of the patriot Paoli. He did not return to England till 1766, but he had not neglected his note-book, and in 1768 published his *Account of Corsica, Journal of a Tour to that Island, and Memoirs of Pascal Paoli.* The book had a very considerable success, not on account of the merits of its historical or descriptive passages, but from the liveliness and truth of the journal, and from the numerous anecdotes and sayings, which brought the Corsican patriot vividly before the English imagination. Johnson's estimate of the work was discriminating and just; and other good judges, though they could not avoid noticing and ridiculing Boswell's extravagances and follies, appreciated at its true value his unrivalled power of biographical narration. The book did much for Paoli, and secured for him sympathy and assistance in England when he was compelled to fly from his native island. The author was for a time intoxicated with his success; he pestered every one with Corsica, introduced himself to Pitt in Corsican dress, and not only appeared at the Shakespeare Jubilee arrayed in the costume of an armed Corsican chief, with "Viva la Libertà" inscribed on his hat, but wrote a full description of his appearance to the *London Magazine.* He certainly gained notoriety, if not fame.

His restless spirit next found occupation in the great Douglas peerage case. He took an intense interest in this affair, acted as an unattached counsel, and published on it a novel and a pamphlet. The often repeated story, that he resented the judgment given by his father in the case to such an extent that he headed the rioters who broke the old judge's windows, is not inconsistent with his character, but as the father's judgment virtually coincided with the son's opinion, it really has no foundation in fact.

In 1769, after numerous love affairs, which are told to his friend Temple with more freedom than decency, he married Miss Montgomerie. Not much is known of this lady, except that she was a relation of the earl of Eglinton, as Boswell took care to inform the people of Scotland in his *Letter* to them in 1785. Johnson's opinion of her qualities was very low; but she probably concurred with old Lord Auchinleck in thinking the great lexicographer "a brute." She seems also to have had rather a contempt for some aspects of Mr Boswell's character, whatever that might "comprehend in his own imagination, and in that of a wonderful number of mankind."

In 1773, though against his father's will, Boswell came to London. He was admitted a member of the Literary Club, and soon after set out with his great friend on the immortal tour to the Hebrides. It was not till many years afterwards that the famous *Journal* was given to the world,—not till after the death of Johnson. Some years after the death of his father in 1782 he had joined the English bar, but he never succeeded in gaining any practice. In 1785 the *Journal of a Tour to the Hebrides* was published, and preparations set on foot for an extended *Life of Johnson.* The collection of materials and careful revision occupied several years, and though Boswell sometimes was despondent, yet on the whole he looked with well-grounded confidence for success. He was absolutely certain that his "mode of biography, which gives not only a *history* of Johnson's *visible* progress through the world, and of his publications, but a view of his mind in his letters and conversations, is the most perfect that can be conceived, and will be more of a life than any work that has ever yet appeared." His expectations were not deceived. The book, which appeared in 1791, was received with the greatest eagerness and delight; and in 1793 a second edition was published. The author's triumph and self-satisfaction were complete; but meantime the evil habits he had contracted during a dissipated life were ruining his health, both of mind and body. He was in his later years an habitual drunkard, and the hypochondria, from which he had always suffered at intervals, terribly increased. He died after a short illness on the 19th May 1795, at the age of 55.

Boswell's character is curious and somewhat contradictory. He was vain of his birth, and of his own talents, sensual and self-indulgent, inquisitive and undignified; and all these faults he parades with a perfectly childish naïveté;—not certainly without consciousness that they were faults, for he is constantly repenting of his sins and framing the best of resolutions, swearing "like an ancient Pythagorean to observe silence, to be grave and reserved though cheerful and communicative." "One great fault of mine," he says, "is talking at random. I will guard against it." But he was, as he has himself admitted, "utterly wanting in solidity and force of mind." His egotism and vanity were excessive, and he exposes these qualities with the greatest frankness to his friend Temple. "I, James Boswell, Esq.," he writes on one occasion,—"you know what vanity that name includes." And again with reference to one of his rivals in Johnsonian literature, he writes; "Hawkins is, no doubt, very malevolent; observe how he talks of me as quite unknown." The peculiar weakness of his intellect and exuberance of his spirits hurried him into absurdities and follies, and made him the butt of the society in which he moved. Yet he was far from having no redeeming qualities. He was genial and friendly, of cultured literary taste, and of no mean powers of mind. It was not a mere frivolous, foolish, prating sot who could appreciate the great qualities of Johnson, and devote himself to a friendship from which he derived no profit and little praise. And assuredly it was not by his unrivalled powers as a fool that Boswell has produced the best biography the world has yet seen. He was not only, as Macaulay admits, a man of quick observation and retentive memory, but he had also grasped with complete consciousness the true idea of biography, which he had learned from his great teacher. Johnson valued biography, because it gives us what comes home to ourselves: he thought that no one could write a real life unless he had lived in social intercourse with the man of whom he wrote, and laid it down as the duty of a biographer to give a full account of the person whose life he is writing, and to discriminate him from all other persons, by any peculiarities of character or sentiment he may happen to have. All these hints were taken hold of and assimilated by Boswell, and the result was a biography which has no equal in our own or in any other literature, which, so far from losing its popularity, is as much esteemed now as when first given to the world, and on which it seems superfluous even to bestow laudation. Johnson was undoubtedly a great man, but he would never have been to us more than a mere name had it not been for Boswell's life. Through that life he is known to us as no other English writer is; his faults and weaknesses, his grand powers of mind and rugged moral strength,—his whole personality is revived for

us. We know him as he actually lived and moved among his fellow-men. The very lights and shades thrown on his character by the narrative give it additional force, for they convince us of its intense truth and reality. Nor is it only as a life of Johnson that Boswell's book has value for us; it is the most important contribution yet made to a knowledge of actual living and thinking in the 18th century. "It is not speaking with exaggeration," says Carlyle, "but with strict measured sobriety, to say that this book of Boswell's will give us more real insight into the history of England, during those days, than twenty other books, falsely entitled 'Histories,' which take to themselves that special aim."

A short memoir of Boswell was written by Malone and will be found in Nichol's *Literary Anecdotes*. It is also reprinted, with some extracts from Boswell's letters to Malone, in the edition of the *Life* published by Bohn, 1859. The *Letters to W. J. Temple and Andrew Erskine* were printed in 1857; in the introduction will be found a pretty complete notice of Boswell's minor writings. *Boswelliana* have been published in the second volume of the Philobiblon Society Miscellanies, 1855–6, and by Dr Charles Rogers, 1874. Editions of Boswell's great work are very numerous; perhaps the amended form of Croker's first edition, by Wright (Bohn, 10 vols., 1859), is the most helpful. The famous essays on Boswell by Macaulay and Carlyle may be taken as mutually corrective and supplementary.

BOTANY

THE science of Botany includes everything relating to the Vegetable Kingdom, whether in a living or in a fossil state. Its object is not, as some have supposed, merely to name and arrange the vegetable productions of the globe. It embraces a consideration of the external forms of plants—of their anatomical structure, however minute—of the functions which they perform—of their arrangement and classification—of their distribution over the globe at the present and at former epochs—and of the uses to which they are subservient. It examines the plant in its earliest state of development, when it appears as a simple cell, and follows it through all its stages of progress until it attains maturity. It takes a comprehensive view of all the plants which cover the earth, from the minutest lichen or moss, only visible by the aid of the microscope, to the most gigantic productions of the tropics. It marks the relations which subsist between all members of the vegetable world, and traces the mode in which the most despised weeds contribute to the growth of the mighty denizens of the forest.

The plants which adorn the globe more or less in all countries must necessarily have attracted the attention of mankind from the earliest times. The science that treats of them dates back to the days of Solomon, for that wise monarch "spake of trees," from the cedar of Lebanon to the hyssop on the wall. The Chaldeans, Egyptians, and Greeks were the early cultivators of science, and Botany was not neglected, although the study of it was mixed up with crude speculations as to vegetable life, and as to the change of plants into animals. Æsculapius and his priests, the Asclepiades, who studied the art of medicine, had their attention directed to plants in a pharmaceutical point of view. About 300 years before Christ Theophrastus wrote a *History of Plants*, and described about 500 species used for the treatment of diseases. Dioscorides, a Greek writer, who appears to have flourished about the time of Nero, issued a work on Materia Medica. The elder Pliny described about a thousand plants, many of them famous for their medicinal virtues. Asiatic and Arabian writers also took up this subject. Little, however, was done in the science of botany, properly so called, until the 16th century of the Christian era, when the revival of learning dispelled the darkness which had long hung over Europe. Brunfels, a physician of Bern, has been looked upon as the restorer of the science in Europe. He published a *History of Plants*, illustrated by figures, about the beginning of the 16th century.

One of the earliest attempts at a methodical arrangement of plants was made in Florence by Andreas Cæsalpinus, a native of Arezzo, some time professor of botany at Padua, and afterwards physician to Pope Clement VIII. He is called by Linnæus *primus verus systematicus*. In his work *De Plantis*, published at Florence in 1583, he distributed the 1520 plants then known into fifteen classes—the distinguishing characters being taken from the fruit.

John Ray, a native of Essex, did much to advance the science of botany. He was born in 1628, and died in 1705. He promulgated a system which may be considered as the dawn of the "natural system" of the present day (Ray, *Methodus Plantarum*, 1682). He separated flowering from flowerless plants, and divided the former into Dicotyledons and Monocotyledons. His orders were founded on a correct idea of the affinities of plants, and he far outstripped his contemporaries in his enlightened views of arrangement.

About the year 1670 Dr Robert Morison[1] of Aberdeen published a systematic arrangement of plants. He divided them into eighteen classes, distinguishing plants according as they were woody or herbaceous, and taking into account the nature of the flowers and fruit. In 1690 Rivinus[2] promulgated a classification founded chiefly on the forms of the flowers. Tournefort[3] about the same time took up the subject of vegetable taxonomy. He was a contemporary of Ray, and was professor of botany at Paris in 1683. He was long at the head of the French school of botany, and published a systematic arrangement in 1694–1700. He described about 8000 species of plants, and distributed them into twenty-two classes, chiefly according to the form of the corolla, distinguishing herbs and under-shrubs on the one hand from trees and shrubs on the other. The system of Tournefort was for a long time adopted on the Continent, but was ultimately displaced by that of Linnæus.

Carl von Linné, or, as he is commonly called, Linnæus,[4] was born on the 23d of May 1707, at the village of Rooshoolt (Råshult), in Smaland, a province of Sweden, where his father, Nicholas Linnæus, was clergyman. He entered as a pupil at the University of Lund, and about the years 1727–28 was received into the house of Stobæus, a physician in that city, where he had abundant opportunities of prosecuting natural history. He afterwards proceeded to Upsal, and had to struggle with great difficulties during his studies there. He aided Celsius in his *Hierobotanicon*, or account of the plants of Scripture, and he became assistant to Rudbeck, professor of botany. He afterwards travelled in Lapland, took his degree in Holland, visited

[1] Morison, *Præludia Botanica*, 1672; *Plantarum Historia Universalis*, 1680.

[2] Rivinus (Augustus Quirinus) paterno nomine Bachmann, *Introductio generalis in Rem Herbariam*, Lipsiæ, 1690.

[3] Tournefort, *Élémens de Botanique*, 1694; *Institutiones Rei Herbariæ*, 1700.

[4] Linnæus, *Systema Naturæ*, 1735; *Genera Plantarum*, 1737; *Philosophia Botanica*, 1751; *Species Plantarum*, 1753

England, and commenced practice in Stockholm, where he lectured on botany and mineralogy. He finally became professor of botany at Upsal, and was one of the most popular lecturers of the day. He died on the 8th of January 1778, in the 71st year of his age. His herbarium is now in the possession of the Linnean Society.

One of his biographers, in summing up his merits, says, —"Educated in the severe school of adversity, accustomed from his earliest youth to put a high value on verbal accuracy and logical precision, endowed with a powerful understanding, and capable of undergoing immense fatigue, both of body and mind, Linnæus produced a most important revolution in botanical science. He improved the distinctions of genera and species, introduced a better nomenclature on the binomial method, and invented a new and comprehensive system founded on the stamens and pistils. His verbal accuracy and the remarkable terseness of his technical language reduced the crude matter that was stored up in the folios of his predecessors into a form which was accessible to all men. He separated with singular skill the important from the unimportant in their descriptions. He arranged their endless synonyms with a patience and a lucid order that were quite inimitable. By requiring all species to be capable of a rigorous definition, not exceeding twelve words, he purified botany from the endless varieties of the gardeners and herbalists; and by applying the same strict principles to genera, and reducing every character to its differential terms, he got rid of the cumbrous descriptions of the old writers. It is said of Linnæus, that, although no man of science ever exercised a greater sway, or had more enthusiastic admirers, yet his merit was not so much that of a discoverer as of a judicious and strenuous reformer. The knowledge which he displayed, and the value and simplicity of the improvements which he proposed, secured the universal adoption of his suggestions, and crowned him with a success altogether unparalleled in the annals of science."

The system of Linnæus is founded on the sexes of plants, and hence it is often denominated the sexual system. It is called an artificial method, because it takes into account only a few marked characters in plants, and does not propose to unite them by natural affinities. It is an index to a department of the book of nature, and as such is useful to the student. It does not aspire to any higher character, and although it cannot be looked upon as a scientific and natural arrangement, still it has a certain facility of application which commends it to the tyro. In using it, however, let it ever be remembered, that it will not of itself give the student any view of the true relations of plants as regards structure and properties, and that by leading to the discovery of the name of a plant, it is only a stepping-stone to the natural system. Linnæus himself claimed nothing higher for it. He says—"Methodi Naturalis fragmenta studiose inquirenda sunt. Primum et ultimum hoc in botanicis desideratum est. Natura non facit saltus. Plantæ omnes utrinque affinitatem monstrant, uti territorium in mappa geographica." Accordingly, besides his artificial index, he also promulgated fragments of a natural method of arrangement.

The Linnean system was strongly supported by Sir James Edward Smith, who adopted it in his *English Flora*, and who also became possessor of the Linnean collection. The system was for a long time the only one taught in the schools of Britain, even after it had been discarded by those in France and in other Continental countries.

The foundation of Botanic Gardens during the 16th and 17th centuries did much in the way of advancing botany. They were at first appropriated chiefly to the cultivation of medicinal plants. This was especially the case at universities, where medical schools existed. The first Botanic Garden was established at Padua in 1545, and was followed by that of Pisa. The garden at Leyden dates from 1577, that at Leipsic from 1579. Gardens also early existed at Florence and Bologna. The Montpellier Garden was founded in 1592, that of Giessen in 1605, of Strasburg in 1620, of Altorf in 1625, and of Jena in 1629. The Jardin des Plantes at Paris was established in 1626, and the Upsal Garden in 1627. The Botanic Garden at Oxford was founded in 1632. The garden at Edinburgh was founded by Sir Andrew Balfour and Sir Robert Sibbald in 1670, and, under the name of the Physic Garden, was placed under the superintendence of James Sutherland, afterwards professor of botany in the university. The park and garden at Kew date from about 1730. The garden of the Royal Dublin Society at Glasnevin was opened about 1796; that of Trinity College, Dublin, in 1807; and that of Glasgow in 1818. The Madrid Garden dates from 1763, and that of Coimbra from 1773. Gesner states that at the end of the 18th century there were 1600 Botanic Gardens in Europe.

A new era dawned on botanical classification when Antoine Laurent de Jussieu appeared. He was born at Lyons in 1748, and was educated at Paris under the care of his uncle, Bernard de Jussieu. At an early age he became botanical demonstrator in the Jardin des Plantes, and was thus led to devote his time to the science of botany. Being called upon to arrange the plants in the garden, he necessarily had to consider the best method of doing so, and adopted a system founded in a certain degree on that of Ray, in which he embraced all the discoveries in organography, adopted the simplicity of the Linnean definitions, and displayed the natural affinities of plants. His *Genera Plantarum*, begun in 1778, and finally published in 1789, indicated an important advance in the principle of classification. Jussieu subsequently became professor of rural botany; he died in 1836 at the age of 88.

The system of Jussieu made its way slowly in Great Britain, and it was not until Robert Brown brought it under notice that it was adopted.[1] It is now the basis of all natural classifications. One of the early supporters of this natural method was Augustin Pyrame De Candolle, who was born in 1778, and who, after attending the lectures of Vaucher at Geneva, devoted himself to botanical pursuits. He subsequently prosecuted his studies at Paris, and lectured on botany at the College of France. He commenced his publications in 1802, and in 1804 he promulgated his *Elementary Principles of Botany*. In 1807 he became professor of botany at Montpellier, and in 1816 he was appointed to the chair of natural history at Geneva, with the charge of the Botanic Garden. In that city he carried on his future botanical labours, and began his *Prodromus Systematis Naturalis Regni Vegetabilis*, which was intended to embrace an arrangement and description of all known plants. He was enabled to complete eight volumes of the work before his death, and it has since been carried on by his son Alphonse De Candolle, with the aid of other eminent botanists. It now embraces descriptions of the genera and species of Dicotyledonous plants. The system followed by De Candolle is a modification of that of Jussieu, and it is adopted more or less at the present day. De Candolle's own herbarium was extremely rich. He had visited and carefully examined many of the most extensive collections, especially those of Paris; and many entire collections, as well as separate families, on which he was specially engaged, were from time to time submitted to his examination by their possessors. He had thus

[1] Brown, *Prodromus Floræ Novæ Hollandiæ*, 1810.

opportunities of comparison greatly beyond what in ordinary circumstances fall to the lot of an individual. His library, too, was stored with almost every important publication that could be required for his undertaking. With such ample materials, aided by his untiring zeal and the persevering energy of his character, he steadily pursued his allotted task, and only ceased to labour at it when he ceased to live. For some years his health declined, and it is to be feared that the severe and incessant attention which he paid to the elaboration of the great family of Compositæ had made a deep inroad upon it. As a relaxation from his labours he undertook in the last years of his life a long journey, and attended the scientific meeting held at Turin; but he did not derive from this the anticipated improvement in his health, which gradually failed until his death on the 9th September 1841. Since De Candolle's time various modifications of his system have been introduced by Endlicher, Lindley, Hooker, and Bentham.

In arranging plants according to a natural method, we require to have a thorough knowledge of structural and morphological botany, and hence we find that the advances made in these departments have materially aided the efforts of systematic botanists.

Robert Brown, a Scottish botanist, was the first in this country to support and advocate the natural system of classification. The publication of his *Prodromus Floræ Novæ Hollandiæ*, according to the natural method, led the way to the adoption of that method in the universities and schools of Britain. Sir William (then Dr) Hooker, in his prelections in the University of Glasgow, and in his numerous writings, ably supported Brown. John Lindley also came into the field, and in 1830 published the first edition of his *Introduction to the Natural System*. Dr Robert Kaye Greville and Dr Walker Arnott were able coadjutors, more especially in the department of Cryptogamic Botany. From the year 1832 up to 1859 great advances were made in systematic botany, both in Britain and on the continent of Europe. Endlicher's *Enchiridion* and *Genera Plantarum*, De Candolle's *Prodromus*, and Lindley's *Vegetable Kingdom* became the guides in systematic botany, according to the natural system.

The following remarks embrace the views of Mr Bentham on the change from the Linnean to the natural system of classification:—"The change from the technical to the scientific study of plants was now complete. The Linnean platform, established on the relation of genera and species, had now been so long and so universally adopted as the basis or starting point, that the credit due to its founder was almost forgotten, and it was superseded by the Jussieun method, although it was chiefly by the consistent following out the principles laid down by Linnæus himself that the change had been effected. Plants were now grouped upon a philosophical study of their affinities, whether morphological, structural, or physiological."

In all classification it is necessary to define what is meant by species. The usual definition of the term has been that a species (as regards the present epoch of the earth's history) is an assemblage of individuals having characters in common, and coming from an original stock or protoplast, and their seeds producing similar individuals. It was also supposed that variation in species was restrained within certain limits, and that varieties had a tendency to revert to the parent form. The view, however, adopted by many now-a-days is, that the tendency to variation is continuous, and that, after a lapse of long periods of time, and under the influence of varying external conditions, the descendants from a common stock may exhibit the differences which characterize distinct species. These are the views which are advanced by Darwin, and which imply a complete revolution in our idea of species. This theory is thus stated by Bentham:—

1. That although the whole of the numerous offspring of an individual plant resemble their parent in all main points, there are slight *individual* differences.
2. That among the few who survive for further propagation, the great majority, under ordinary circumstances, are those which most resemble their parent, and thus the *Species* is continued without material variation.
3. That there are, however, occasions when certain individuals, with slightly diverging characters, may survive and reproduce races, in which these divergencies are continued even with increased intensity, thus producing *Varieties*.
4. That in the course of an indefinite number of generations circumstances may induce such an increase in this divergency, that some of these new races will no longer readily propagate with each other, and the varieties become *New Species*, more and more marked as the unaltered or less altered races, descendants of the common parent, have become extinct.
5. That these species have in their turn become the parents of groups of species, that is *Genera*, *Orders*, &c., of a higher and higher grade, according to the remoteness of the common parent, and more or less marked, according to the extinction or preservation of unaltered primary, or less altered intermediate, forms.

As there is thus no difference but in degree between a variety and a species, between a species and a genus, between a genus and order, all disputes as to the precise grade to which a group really belongs are vain. It is left in a great measure to the judgment of the systematist, with reference as much to the use to be made of his method as to the actual state of things, how far he should go in dividing and subdividing, and to which of the grades of division and subdivision he shall give the names of Orders, Sub-orders, Tribes, Genera, Subgenera, Sections, Species, Sub-species, Varieties, &c., with the consequent nomenclature.

Such a systematic arrangement is founded on a hypothesis which, so far as the present flora of the globe is concerned, cannot be demonstrated. Conjecture is hazarded as to the present epoch of the earth's history, by extending back to unlimited ages. If the theory is consistent with what we see around us, and is founded on plausible grounds, then we must think that we have ascertained the plan followed by the great Creator, Designer, and Upholder of all things, that we have been able to ascertain and follow His workings, and the mode in which He has created the diverse plants which have covered our globe in time and space. This new phase of systematic botany, however, requires more definite data to lead to its adoption as an explanation of the plan of creation.

The Physiology of plants did not keep pace with the advance in Classification. Grew and Malpighi were the earliest discoverers in this department of botany. Hales also contributed to it by his observations on the motion of fluids in plants. The subject of fertilization was one which early excited attention.

The idea of the existence of separate sexes in plants was entertained in early times, long before separate male and female organs had been demonstrated. The production of Dates in Egypt, by bringing two kinds of flowers into contact, proves that in very remote periods some notions were entertained on the subject. Female Date Palms only were cultivated, and wild ones were brought from the desert in order to fertilize them. Herodotus informs us that the Babylonians knew of old that there were male and female Date-trees, and that the female required the concurrence of the male to become fertile. This fact was also known to the Egyptians, the Phœnicians, and other nations of Asia and Africa. The Babylonians suspended male clusters from wild Dates over the females; but they seem to have supposed that the fertility thus produced depended on the presence of small flies among

the wild flowers, which, by entering the female flowers, caused them to set and ripen. The process was called palmification. Theophrastus, who succeeded Aristotle in his school in the 114th Olympiad, frequently mentions the sexes of plants, but he does not appear to have determined the organs of reproduction. Pliny, who flourished under Vespasian, speaks particularly of a male and female Palm, but his statements were not founded on any real knowledge of the organs. From Theophrastus down to Cæsalpinus, who died at Rome in 1603, there does not appear to have been any attention paid to the reproductive organs of plants. Cæsalpinus had his attention directed to the subject, and he speaks of a halitus or emanation from the male plants causing fertility in the female.

Grew seems to have been the first to describe, in a paper on the *Anatomy of Plants*, read before the Royal Society in November 1676, the functions of the stamens and pistils. Up to this period all was vague conjecture. Grew speaks of the *attire*, or the stamens, as being the male parts, and refers to conversations with Sir Thomas Millington, Savilian professor at Oxford, to whom the credit of the sexual theory seems really to belong. Grew says that, "when the attire or apices break or open, the globules or dust falls down on the seedcase or uterus, and touches it with a prolific virtue." Ray adopted Grew's views, and states various arguments to prove their correctness in the preface to his work on European plants, published in 1694. In 1694 Camerarius, professor of botany and medicine at Tübingen, published a letter on the sexes of plants, in which he refers to the stamens and pistils as the organs of reproduction, and states the difficulties he had encountered in determining the organs of Cryptogamic plants. In 1703 Samuel Morland, in a paper read before the Royal Society, stated that the farina (pollen) is a congeries of seminal plants, one of which must be conveyed into every ovum or seed before it can become prolific. In this remarkable statement he seems to anticipate in part the discoveries afterwards made as to pollen tubes, and more particularly the peculiar views promulgated by Schleiden. In 1711 Geoffroy, in a memoir presented to the Royal Academy at Paris, supported the views of Grew and others as to the sexes of plants. He states that the germ is never to be seen in the seed till the apices (anthers) shed their dust; and that if the stamina be cut out before the apices open, the seed will either not ripen, or be barren if it ripens. He mentions two experiments made by him to prove this—one by cutting off the staminal flowers in Maize, and the other by rearing the female plant of Mercurialis apart from the male. In these instances most of the flowers were abortive, but a few were fertile, which he attributes to the dust of the apices having been wafted by the wind from other plants.

Linnæus was the next botanical author who took up the subject, and by his sexual system he may be said to have opened a new era in the history of botany. He first published his views in 1736, and he thus writes—"Antheras et stigmata constituere sexum plantarum, a palmicolis, Millingtono, Grewio, Rayo, Camerario, Godofredo, Morlando, Vaillantio, Blairio, Jussievio, Bradleyo, Royeno, Logano, &c., detectum, descriptum, et pro infallibili assumptum; nec ullum, apertis oculis considerantem cujuscunque plantæ flores, latere potest." He divided plants into sexual and asexual, the former being Phanerogamous or flowering, and the latter Cryptogamous or flowerless. In the latter division of plants he could not detect stamens and pistils, and he did not investigate the mode in which their germs were produced. He was no physiologist, and did not promulgate any views as to the embryogenic process. His followers were chiefly engaged in the arrangement and classification of plants, and while descriptive botany made great advances the physiological department of the science was neglected. His views were not, however, adopted at once by all, for we find Alston stating arguments against them in his *Dissertation on the Sexes of Plants*. Alston's observations were founded on what occurred in certain unisexual plants, such as Mercurialis, Spinach, Hemp, Hop, and Bryony. The conclusions at which he arrives are those of Pontedera, that the pollen is not in all flowering plants necessary for impregnation, for that fertile seeds can be produced without its influence. He supports parthenogenesis in some plants. Soon after the promulgation of Linnæus's method of classification, the attention of botanists was directed to the study of Cryptogamic plants, and the valuable work of Hedwig on the reproductive organs of Mosses made its appearance in 1782. He was one of the first to point out the existence of certain cellular bodies in these plants which appeared to perform the functions of reproductive organs, and to them the name of *antheridia* and *pistillidia* were given. This opened up a new field of research, and led the way in the study of Cryptogamic reproduction, which has since been much advanced by the labours of numerous botanical inquirers. The interesting observations of Morland, already quoted, seem to have been neglected, and no one attempted to follow in the path which he had pointed out. Botanists were for a long time content to know that the scattering of the pollen from the anther, and its application to the stigma, were necessary for the production of perfect seed, but the stages of the process of fertilization remained unexplored. The matter seemed involved in mystery, and no one attempted to raise the veil which hung over the subject of embryogeny. The general view was, that the embryo originated in the ovule, which was in some obscure manner fertilized by the pollen.

In 1815 Treviranus roused the attention of botanists to the development of the embryo, but although he made valuable researches, he did not add much in the way of new information. In 1823 Amici discovered the existence of pollen tubes, and he was followed by Brongniart and Brown. The latter traced the tubes as far as the nucleus of the ovule. These important discoveries mark a new epoch in embryology, and may be said to be the foundation of the views now entertained by physiologists, which have been materially aided by the subsequent elucidation of the process of cytogenesis, or cell-development, by Schleiden, Schwann, Mohl, and others. The whole subject has been investigated recently with great assiduity and zeal by physiologists, as regards both Cryptogamous and Phanerogamous plants. The formation of germinal vesicles in the ovule, and the development of the embryo in flowering plants, have been fully considered by Griffith, Schleiden, Mirbel, Spach, Meyen, Schacht, Mohl, Unger, Naudin, Radlkofer, and others; the embryogenic process in Coniferous plants and in the higher Cryptogams by Hofmeister, Henfrey, Suminski, Mettenius, Strasburger, Eichler, Baillon, Cohn, Pringsheim, Millardet; and that of the lower Cryptogams by Thuret, Bornet, Decaisne, and Tulasne. The observations of Darwin as to the fertilization of Orchids, Primula, Linum, and Lythrum, and the part which insects take in this function, have opened up a new era in Physiological Botany. He has been followed by Hermann Müller. Darwin's experiments in reference to the movements of climbing and twining plants, and of leaves in insectivorous plants, have opened up a wide field of inquiry which he has cultivated with eminent success and with most important results. Among other authors who have contributed to the advance of Vegetable Physiology may be named Hoffmann, Sachs, Van Tieghem, Prillieux, Deherain, and Famintzen. We have thus been enabled to come to certain general conclusions on this obscure subject, and

future observers have been directed in the proper path of investigation.

In the Physiological department of botany the most important researches have been made by French and German botanists. The laboratories in connection with schools in Germany offer facilities for study which do not exist to the same extent in Britain. Physiological researches demand not only a Botanic Garden with its appendages, but apparatus of various kinds, means of prosecuting histological and chemical investigations, physical experiments, and observations by the spectroscope. Our schools require then not only lecture-rooms, but laboratories well fitted up with all needful appliances, and salaried assistants to aid the teachers in their demonstrations and the pupils in their practical work.

The department of Geographical Botany has made rapid advance by means of the various scientific expeditions which have been sent to all quarters of the globe; and the question of the mode in which the floras of islands and of continents have been formed has given rise to important speculations by such eminent botanical travellers as Darwin and Hooker. The latter has published a valuable paper on insular floras. Under this department the connection between climate and vegetation has been carefully studied both by botanists and by meteorologists. Among the contributors to this department of botany the following authors may be noticed—Humboldt, Schouw, Meyen, Berghaus, Martius, Harvey, Hooker.

The subject of Palæontological Botany has been much advanced of late by the researches of botanists and geologists. The use of the microscope in the examination of tissues has aided much in the determination of fossil plants. The more accurate study of Organography has also been the means of correcting errors in diagnosis. The nature of the climate at different epochs of the earth's history has also been determined from the character of the flora. The works of Brongniart, Goeppert, and Schimper have advanced this department of science. Among others who have contributed valuable papers on the subject may be noticed Heer, who has made observations on the Miocene flora, especially in Arctic regions; Saporta, who has examined the Tertiary flora; Dawson and Lesquereux, who have reported on the Canadian and American fossil plants; and Williamson, who has made a careful examination of many of the coal fossils, and whose excellent drawings of structure have opened a new light on the character of many of the genera. Delineations of fossils by Witham, Lindley and Hutton, and Carruthers, have tended much to advance our knowledge of the fossil flora of Britain.

Botany may be divided into the following departments:—1. *Structural* Botany, having reference to the anatomical structure of the various parts of plants, including Vegetable Histology, or the microscopic examination of tissues; 2. *Morphological* Botany, the study of the form of plants and their organs—(these two departments are often included under the general term of Organography); 3. *Physiological* Botany, by some termed Organology, the study of the life of the entire plant and its organs, or the consideration of the functions of the living plant; 4. *Systematic* Botany, the arrangement and classification of plants; 5. *Geographical* Botany, the consideration of the mode in which plants are distributed over the different regions of the globe; 6. *Palæontological* Botany, the study of the forms and structures of the plants found in a fossil state in the various strata of which the earth is composed.

In the present article we shall confine our attention to the Structure and Morphology of Plants. The limits and classification of the Vegetable Kingdom have been partly considered under BIOLOGY (vol. iii. pp. 690–696). The Classification of Plants will be taken up *in extenso* under the heading VEGETABLE KINGDOM, and the Distribution of Plants in space and time will be treated of in separate articles.

STRUCTURAL ELEMENTS OF PLANTS.

The elementary structure which is the foundation of all vegetable tissue is the *cell*. In the young succulent bud of a growing stem each cell consists of an outer firm, elastic membrane of cellulose constituting a *cell-wall*; within this, a gelatinous soft mass of *protoplasm*, of which there may be a portion distinctly marked off as a *nucleus*; and, enclosed by the protoplasm, a cell-cavity containing a more or less watery fluid, the *cell-sap* (fig. 1). Such may be taken as the structure of a typical vegetable cell, which is thus a closed vesicle or sac with fluid or semi-fluid contents. Of these elements of the cell the protoplasm is that which is essential for its growth and development. In it are contained all the substances requisite for the formation of the cell-wall and the cell-sap; and the nucleus is merely a differentiated portion of it. From it then all the other parts of the cell are formed, and it is essential to the growth of the cell. Hence it has received the appellation of *primordial cell*; and, indeed, amongst many Algæ it exists for some time as a separate cell without any cell-wall or other part. This must be borne in mind when defining the cell as a sac or vesicle. The growth of the cell is usually, at first, uniform throughout, and it has therefore a more or less rounded form; but, according to the function which it is destined eventually to perform, one or other, or it may be all, of the parts of the cell become modified or specially developed. The cell-wall may be greatly thickened; or it may grow more in one direction than another, so as to be elongated and form protuberances; or perforations may occur; or several similar cells arranged in a longitudinal series may, by obliteration of the interposed septa, unite to form a long tube which is then called a *vessel*. The protoplasm in the process of growth may be completely absorbed; and when this occurs growth ceases, and the cell-walls form merely a framework. It may, however, remain a long time, assuming various shapes and often uniting with colouring matters. The cell-sap also may disappear or may remain, containing in solution, or as definite forms in its mass, various assimilative substances, as fat granules, oil globules, starch, mineral crystals, &c. The cell.

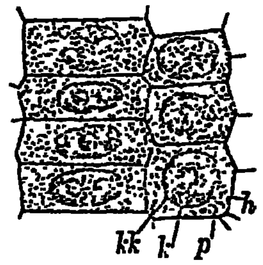

Fig. 1.

Young cells from root of *Fritillaria imperialis*. *h*, cell-wall; *p*, protoplasm; *k*, nucleus; *kk*, nucleolus. (*Sachs.*)

In some plants, as amongst Algæ (Protococcus), one cell alone performs all the functions necessary for the existence of the plant. We have thus in this cell an epitome of vegetable life, and this is the most perfect form of cell. As we pass to the higher forms of plants, where many cells are united, we find a physiological specialization taking place, by which certain cells are set apart for assimilation, some being embryonal, some supporting, and others protective, &c. Amongst such plants as Ferns and ordinary Flowering Plants a further differentiation takes place, and some of these cells unite to form true vessels. We thus have a means of arranging all plants in two groups, viz., those whose tissues consist entirely of cells, *cellular plants* (including Fungi, Algæ, Mosses, &c.); and those in which vessels are present, *vascular plants* (including Ferns, Lycopods, and ordinary Flowering Plants).

1. *Cells and Vessels—Cellular and Vascular Tissues.*

Cells united together constitute *cellular tissue* (fig. 2).

Cells and vessels. It exists in all plants and abounds in fleshy roots, stems, leaves, and in succulent fruits. It constitutes the pith and outer bark of trees, and is very abundant in the centre of the stem of the Aralia (Fatsia) papyrifera, whence Chinese rice-paper is derived by cutting it into thin sheets. By cultivation the Turnip, Carrot, Cabbage, and other esculent vegetables acquire much cellular tissue, and become tender and succulent. The cells of the tissue vary much in size. In a cubic inch of a leaf of the Carnation there are said to be upwards of three millions of cells. They are frequently seen $\frac{1}{1000}$th, $\frac{1}{500}$th, and $\frac{1}{300}$th of an inch in diameter. In some of the Cucumber tribe, and in the pith of aquatic plants, cells $\frac{1}{50}$th and $\frac{1}{30}$th of an inch in diameter occur.

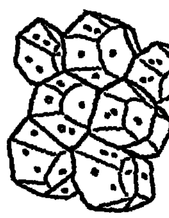

Fig. 2.
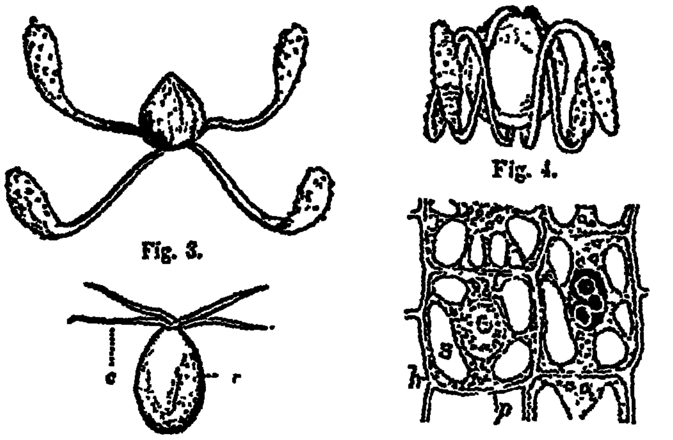
Hexagonal complete cellular tissue from the pith of the Elder.

The cell-wall. In young cells the cell-wall is a thin membrane consisting of *cellulose*, with some water and a certain amount of incombustible material. It is permeable by water, is slightly extensible and elastic, and is colourless. It dissolves in sulphuric acid, and upon addition of iodine and sulphuric acid assumes a deep blue colour. By intussusception of nutrient material, *i.e.*, the interposition of new molecules between those pre-existing, the cell-wall increases both in surface-extent and in thickness. The resulting cell-wall is not, however, uniform in its structure, but is composed of lamellæ of different refractive power, in which the cellulose is combined alternately with much and with little water. These alternating dense and watery layers,—of which one set is concentric with the cell-wall, whilst two other series are vertical or oblique to the surface of the cell-wall, and cut the concentric ones throughout the whole thickness of the wall,—under a high power of the microscope present a series of mutually intersecting lines, and constitute respectively what are termed the *stratification* and *striation* of the cell-wall.

Independently of these changes in the structure of the cell-wall, consequent on its increase in surface-extent and thickness, which will be presently noticed, there are other changes of a chemical nature which take place during the growth of the cell, and which so affect its wall as to break it into distinct "shells," which differ both chemically and physically from the original cell-wall. Thus, in the epidermis or outer cellular covering of plants, the outermost portion of the outer wall of the cells becomes converted into an elastic substance, quite impervious to water, which acts as a protective covering. This substance is known as cork or cuticular matter. Another alteration is the conversion of the layers of the cell-wall into woody matter, by a process of *lignification*, or formation of wood. Or, again, layers of the cell-wall may be converted into mucilaginous substance, *i.e.*, absorbing water, and becoming gelatinous, as in the cells of pith of Astragalus Tragacantha,—which furnishes gum tragacanth,—and the outer cells of the seed of the Common Flax. Lastly, mineral matters may be deposited in the cell-wall, such as lime, silica, &c., so abundantly in some instances as to constitute, after burning, a perfect skeleton of the cell-wall. In all these cases, however, of alteration of layers of the cell-wall, an innermost layer, giving all the reactions of pure cellulose, may be observed. If growth in surface-extent proceeded uniformly over the whole of a cell-wall the resulting structure would be a more or less rounded vesicle; but at different points portions grow more rapidly than at others, and thus cells, originally oval or spherical, may become cylindrical, conical, &c. The changes consequent on unequal growth in thickness are, however, much more important, giving rise to altered appearances both on the outside and inside of the cell-wall. The external thickenings are most usually projections in the form of spines, knobs, &c., as in some pollen-grains, and in cilia connected with the reproductive cells of many Algæ (fig. 3), or club-shaped hygrometric filaments as in Equisetum (figs. 4, 5); whilst the internal ones are more usually ridges—annular, spiral, or reticulate (figs. 11 and 12)—which may proceed so far as almost to obliterate the cavity of the cell-wall.



FIGS. 3 and 4.—Spore or reproductive cell of Equisetum, Horsetail, with two clavate hygrometric filaments. In fig. 3 the filaments are expanded in a dry state; in 4 they are curled round the spore on the application of moisture.
FIG. 5.—Cell r, with vibratile filaments or cilia c, from Chætophora.
FIG. 6.—Older cells than those represented in fig. 1. h, cell-wall; p, protoplasm with nucleus and nucleolus; s, vacuoles in the protoplasm filled with fluid cell-sap. (*Sachs.*)

The *protoplasm*, which lines the interior of the cell-wall, The protoplasm.
and which is the essential living portion of the cell, consists of albuminous substance mixed with water and some incombustible materials, and it also contains some organic compounds. It is a homogeneous, soft, gelatinous substance. As we usually find it in cells it has a granular and turbid appearance. This arises from an admixture of formative matters, to which the name *metaplasm* has been applied. It is coagulated by heat, and is soluble in a dilute solution of caustic potash; iodine solution colours it yellow or brown, whilst strong sulphuric acid at first colours it rose-red, subsequently dissolving it. Usually, at points in the interior, drops of fluid become differentiated as *vacuoli* (fig. 6), which may subsequently coalesce, and thus the protoplasm may become a sac containing cell sap; and if growth of the cell-wall continues the protoplasm eventually forms a mere lining of the cell-wall constituting the *primordial utricle* of Von Mohl. The protoplasm in some cells exhibits phenomena of movement within the cell-wall of a definite character. Thus in the internodal cells of Characeæ (fig. 7) a movement of protoplasm round the longest diameter of the cell is seen, and in the hairs of Tradescantia (Virginian Spiderwort) a circulation of protoplasm occurs. These constitute the phenomena of *rotation* and *circulation*.

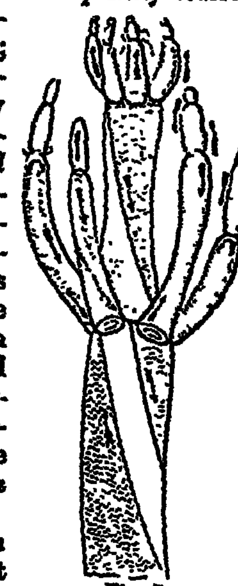


Fig. 7.
A small portion of a Chara magnified to show the intracellular circulation. The arrows mark the direction of the course of the protoplasm in the cells. The clear spaces are parts where there is no movement.

The nucleus (fig. 1, *k*) is present in the cells of all the higher plants. It The nucleus.
is a small rounded differentiated portion of the protoplasm, and frequently contains vacuoles, which are termed *nucleoli* (fig. 1, *kk*). It may be in the centre of the cell or close to the sides, but it may change its position. Portions of the protoplasm are also differentiated as grains or granules, to which colouring matters are attached; but

these will be noticed hereafter. The protoplasm in old cells may disappear, and then all growth ceases, and the cells consist of a mere framework; or it may remain, and then growth of the cell continues. And it is by a re-arrangement of the molecules of this protoplasm that the formation of new cells begins,—the nucleus entering also into the process.

By the term cell-sap is meant the fluid contained in the vacuoli. It consists in great part of water, in which are dissolved various salts, derived from without, and compounds formed by assimilation in the plant itself. Amongst the latter we may mention inulin, a substance closely allied to starch and sugar, found in Composite plants.

The term *parenchyma* (areolar, utricular, or vesicular tissue) is a general name for any form of cellular tissue, in which thin-walled cells of a diameter nearly equal in every direction are united to one another by broad surfaces (fig. 2). If the cells are pointed at both ends and have a length greatly exceeding their breadth, there is formed *prosenchyma* (fig. 8). Both tissues may be *complete* (figs. 2 and 8) or *incomplete* (figs. 9 and 10), *i.e.*, the component cells may touch each other on every side and leave no intercellular spaces, or intercellular spaces may exist between the cells. According to the amount of surface-growth and thickening of the cell-wall various forms of parenchymatous and prosenchymatous tissue result. Thus, in the Rush and Bean we have a stellate parenchyma, with large intercellular spaces (fig. 10), in the Elder pith a complete angular parenchyma (fig 2), and in the succulent stem of the Cactus a spherical incomplete parenchyma (fig. 9). Those forms of tissue in which the individual cells have been altered by thickening of the cell-wall are the most

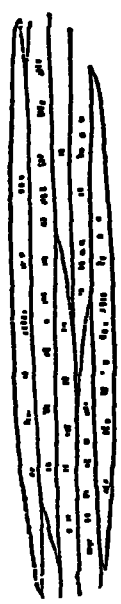

Fig. 8.

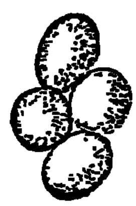

Fig. 9.

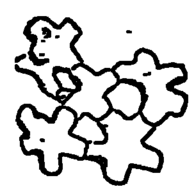

Fig. 10.

FIG. 8.—Prosenchymatous cells. FIG. 9.—Incomplete parenchyma.
FIG. 10.—Stellate or star-like cellular tissue of the Bean, with intercellular spaces or lacunæ.

important; and the alterations in the cell-wall consequent on growth in thickness may be such as to produce obliteration of the septum between superposed cells, and their cavities, freely communicating, then give rise to a tube or vessel, a combination of which constitutes the *vascular tissue* of authors. Whilst this is the nature of a true vessel, considerable confusion has arisen from the term being applied to any cell-like structure in which the longitudinal diameter exceeds the transverse; and thus the difference between a cell and a vessel became one of length only. The term vessel ought to be restricted to such as are formed by coalescence of cells.

Under the term *pleurenchyma* (fig. 8) is included tissue Pleurenchyma.
composed of such elongated prosenchymatous, flexible, thickened cells, as are found in the bast or phloëm layers of ordinary trees. They also occur in the wood portion. Their walls are thickened regularly, and they constitute when united what is commonly known as the woody or bast fibre. The diameter of the woody fibres varies from $\frac{1}{2000}$th to $\frac{1}{250}$th of an inch. The materials used for ropes and cordage, linen, certain Indian muslins, mummy-cloths, and mats consist of the woody fibre of plants from which the more delicate tissues have been removed by maceration in water. Flax or lint is thus procured from the bark of Linum usitatissimum, hemp from Cannabis sativa, New Zealand flax from Phormium tenax, Pita flax from Agave americana, Sun-hemp from Hibiscus cannabinus, and bass or bast from the common Lime or Linden-tree. Fibres are also procured for manufacture from the Pine-apple plant (Ananassa sativa), from Yucca gloriosa, from Böhmeria nivea, which yields the Indian Rheea fibre, from most of the plants belonging to the Mallow and Nettle tribes, and from some Leguminous plants, such as Crotalaria juncea, which supplies a kind of Bengal hemp. If the maceration of the fibre is carried to a great extent, a pulp is formed from which paper is manufactured. Pleurenchyma does not occur in cellular plants, such as Lichens, Sea-weeds, and Mushrooms. The tissues of these plants speedily disappear under the action of water, and hence, perhaps, the reason of their rarity in a fossil state. In the very young state woody cells are delicate, and it is only in proportion as they attain maturity that their walls acquire a thick consistence. In the sap-wood of ordinary trees the woody cells are thickened in their walls, but are pervious; while in the heart-wood they are rendered solid by the thickening matter, which is often variously coloured.

If the thickening of the cell-wall takes place so that a Spiral tissue.
network, ring, or spiral of thickening matter is formed, then the cells are *reticulated*, *annular* (fig. 11), or *spiral* (fig. 12), as in the leaves of Sphagnum, hairs of Cactaceæ, and seed-coat of Casuarina. In these cells the spiral thickening frequently becomes loosened from the cell-wall as a spiral fibre, and can be unrolled. Such forms occur in the outer covering of the seed of Collomia linearis and of the fruit of Salvia Verbenaca. In these, when placed in water, the spirals rupture the softened membrane of the cells, and spread outwards.

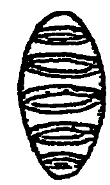

Fig. 11.

FIG. 11.—Annular cell from the Mistleto.
FIG. 12.—Spiral cell from an Orchid.

The spongy elastic character of the outer cellular covering of the roots of tropical Orchids and Araceæ, of Plate X
the sepals of Illecebrum verticillatum, of the pericarp of fig. 2.
Cachrys Morisoni and C. odontalgica, and of the ribs of the fruit of Æthusa Cynapium, is due to the presence of spiral cells. In the reproductive cells of Hepaticæ spiral fibres called *elaters* are found in connection with the spores. Reticulated or netted cells, produced by fibres forming a sort of mesh or network, occur in the wing of the seed of Swietenia, in the pericarp of Picridium tingitanum and P. vulgare, in the seed-coat of Cucurbita Pepo, in the parenchyma of the leaf of Sanseviera guineensis, and in isolated cells of the pith of Rubus odoratus and of Erythrina Corallodendron.

diameter. The spiral thickened portion of the wall of the vessel may become loosened from the membrane of the wall and form a spiral fibre in the interior. These fibres are elastic, usually rounded and simple; but sometimes two or more are combined so as to form a flat band. These flat ribands, consisting of fibres which vary in number from two to twenty-five, or more, are met with abundantly in the stems of Bananas and Plantains, and in the shoots of Asparagus. The spiral in such cases is called compound, and the vessels *pleiotracheæ*. The spiral fibres have such tenacity that when the vessels are ruptured they can be pulled out. This capability of being unrolled characterizes true spiral vessels (fig. 13). When the spiral is not loosened from the cell-wall and cannot therefore be unrolled, it is said to be *closed*. On breaking the young shoots or leaf-stalks of the Geranium, Strawberry, and Rose, or the leaves of the Hyacinth, Amaryllis, and Banana, and pulling the parts gently asunder, the fibres can be easily seen in the form of a fine cobweb. When the aerial stems of the Banana and Plantain are cut across, the spiral fibres may be pulled out in large quantity so as to be used for tinder. Generally, the coils or volutions of the fibre are said to be left-handed, that is, turning to the left of a person supposed to be in the axis. In the

FIG. 15.—An annular vessel taken from the Melon plant.
FIG. 16.—Reticulated vessel taken from the Melon plant.

garden Lettuce vessels are met with, some having the fibre turning to the left, others to the right. In the Scarlet Bean the coils of the fibres are left-handed, while the plant itself turns to the right in twining. Spiral vessels are abundant in young plants and shoots, while in the hard stems of trees and shrubs they chiefly surround the pith. Spiral vessels occasionally exhibit a branched appearance. This may arise from the union of separate vessels, or it may depend on a regular division of the fibres, as is seen in the Mistleto, House-leek, and Gourd (fig. 14). *Annular* vessels are those in which the thickening (or, if it be loosened from the wall of the vessel, the fibre) is in the form of rings (fig. 15). These rings in Mammillaria quadrispina, and in some other plants of the Cactus tribe, are very thick, and leave only a small canal in the centre of the vessel. Annular vessels are from $\frac{1}{300}$th to $\frac{1}{100}$th of an inch in diameter. In *reticulated* vessels (fig. 16) the thickenings take the form of a network. All vessels of this type lose very early their protoplasmic contents, and serve to convey air.

Bordered pits. In the process of thickening of the cell-wall, if large spaces of the cell-wall remain thin, and the thickening mass growing in a circular manner projects into the interior of the cell and gradually arches over the thin portion of cell-wall, a dome-shaped cavity is enclosed betwixt the thin cell-wall and the thickening mass. The growing thickening mass gradually contracts the opening into this cavity, but never completely closes it. On front view this presents the appearance of two concentric circles, an outer marking the edge of the original thin portion of the cell-wall, and an inner indicating the under edge of the gradually contracting ring of thickening matter (fig. 17). When this process takes place on opposite sides of the partition wall between two cells, there are then two similar cavities separated by the thin partition wall of the cells, each communicating freely by a small circular aperture with the cell in which it has been formed (figs. 17 and 18). In process

FIG. 18.—Diagram to show thickening dome on both sides of the partition wall.
FIG. 19.—Partition wall has given way and a single cavity is formed, communicating on both sides with adjacent cells. (*These figures after Sachs.*)

of growth the partition wall is absorbed, and then a lenticular cavity is formed, connected by a circular aperture on each side with adjacent cells (fig. 19). When viewed by transmitted light these present the appearance seen in fig. 17 *t'*; such structures are termed *bordered pits*, and a collection of such cells constitutes the *disk-bearing or punctated tissue* of authors. It is well seen in Firs and other cone-bearing plants. It has been called *glandular* tissue. In the case of some fossil woods, pieces of silica, like double convex lenses, have been found in the cavities. When a vertical radial section is made of the stem of Fir, bordered pits, arranged in two rows, with individual pits on the same level, are seen. In Araucaria double and triple alternating rows are seen; whilst in the Yew a prominent striation line winding spirally amongst the pits is noticeable. When the thickening begins by the formation of transverse ridges extending right across the wall of the cell, and the inwardly projected ridges gradually arch over the thin membranous portion of the wall, a narrow fissure only is left leading into the cavity enclosed by the thickening masses and the thin portion of the partition wall, on the opposite side of which a similar process has proceeded. By the absorption of the partition wall a single cavity between two cells is thus produced, communicating with both, just as in the last case. Viewed by transmitted light these present an appearance like rungs of a ladder, and hence the name *scalariform* applied to the cells in which they occur (fig. 20). They are specially seen in Ferns, where they give rise to long prismatic vessels.

Fig. 20.

Scalariform or ladder-like prismatic vessels of a Tree Fern.

Pitted tissues. When the thickening takes place over nearly the whole of the cell-wall, thin portions may be left here and there, which appear as pits when viewed by transmitted light,

or as small canals when the cell-wall is very thick. Such cells are termed *porous* or *pitted* or *dotted* cells (fig. 21). In old cells, after the protoplasm has disappeared, the portion of the cell-wall which remained thin is often absorbed, and thus there is a true perforation of the cell-wall. These perforations often occur in groups both upon the cell-wall and upon the septum between superposed cells, and give rise to a remarkable sieve-like structure, in which case they are termed *sieve-cells*. The *latticed cells* of some authors are of a similar nature. When superposed porous or sieve-cells coalesce by complete obliteration of the septum, then a *pitted vessel*, *sieve tube*, or *duct* is formed (fig. 22). These ducts are usually of a larger size than other vessels; they are well seen in the inner phloëm layers and in the wood of trees, and they constitute the large rounded openings which are seen in the transverse section of the stems of the Oak, Poplar, Willow, &c. They also abound in the Bamboo (fig. 23), and in other plants of rapid growth. The names of *bothrenchyma* and *taphrenchyma* have been given to a tissue composed of such cells. Not unfrequently contractions are visible on the outside of the vessel (fig. 22), indicating its formation by coalescence of superposed cells. To vessels exhibiting contractions of this kind, whether spiral or pitted, the terms *moniliform* and *vermiform* have been applied; and the tissue composed of these moniliform vessels has been denominated *phleboidal*. In the ducts of many plants a remarkable appearance is produced by the protrusion, through the perforations into the cavity of the vessel, of portions of the adjoining cells, or, before its absorption, of the portion of partition-wall closing the pit. These portions appear as cells filling the interior of the vessel, and are described under the name of *tylosis* (fig. 24). It is well seen in the Walnut, Chestnut, Oak, &c.

FIG. 25.—Branching and anastomosing laticiferous vessels. The arrows make the direction of the current.

Laticiferous vessels. *Laticiferous* vessels (fig 25) consist of long branching tubes or passages, having a diameter of about $\frac{1}{1100}$th of an inch, forming, by their union, an anastomosis or network, like the veins of animals. They are the *milk* vessels and the *proper* vessels of old authors. They receive their name from containing an emulsion called *latex*, of a granular nature, often milky or coloured. They are seen in the India-rubber and Gutta-percha plants, the Mudar plant, the Cow-tree, Spurges, Dandelion, Lettuce, Chicory, and Celandine, frequently containing a large quantity of caoutchouc. Usually these vessels are thin-walled, but sometimes slightly thickened. They are found most abundantly in the phloëm layers—rarely in the xylem or wood layers (Papayaceæ). They are the result of the coalescence of anastomosing or rectilinear rows of cells, and sometimes they seem to have resulted from the conversion of other vessels. In some Araceæ they seem to represent spiral vessels. In Asclepiadaceæ they are evidently bast-fibres. Some consider them as merely intercellular canals. The milky sap of Euphorbia phosphorea is said to be luminous. The latex exhibits movements which have given origin to the name *cinenchyma* applied to laticiferous tissue by some authors. Those movements, classed under the name *cyclosis*, must not be confounded with the motion of protoplasm in cells which is designated rotation.

We have seen that the cellular tissue is sometimes incomplete, that is, the cells do not touch on every side (fig. 9). The intervening spaces are called *intercellular spaces*, and these may be either circumscribed cavities called *lacunæ*, or they may extend for some length through the tissue as *intercellular canals*; but these two structures pass into one another. In the earliest stage of development the tissue is always complete, and these spaces are formed subsequently by a splitting of the partition or common wall of the cells, and they may subsequently be increased in size by an absorption of the investing cells. These lacunæ and canals may contain air, especially in aquatic plants, to give them buoyancy, as in Potamogeton (fig. 26), or they may be receptacles for various secretions, and when they exist as canals they usually aid in conducting sap. The intercellular canals are exceedingly well seen in coniferous plants, where they constitute resin passages, forming a continuous system throughout the plant, and arranged at intervals in concentric circles in the xylem or wood portion of the stem. Intercellular spaces.

Chlorophyll is the green colouring-matter of plants. It occurs in the cells of the superficial parts of plants united with small portions of the protoplasm (*chlorophyll bodies*), which are combined into grains of various forms. Starch-grains are usually abundant in the chlorophyll bodies. Chlorophyll is soluble in alcohol and ether. It consists of four substances, two yellow and two green, which possess distinct optical properties. It gives a black band in the red of the spectrum. Physiologically it is very important. It is developed under the action of light, and undergoes changes according to its state of oxygenation. Hence the varied tints of leaves in autumn. Numerous colouring matters occur in plants, especially in flowers, and all such when not green are included under the general term *chromule*. Starchy and oily matters and albuminoids occur very abundantly in the cells of plants, where they are stored Substances found in cells.

Starch. for the purposes of nutrition. Starch, composed chemically of carbon and the elements of water (hydrogen and oxygen), its formula being $C_6H_{10}O_5$, occurs in the form of fine grains, more or less oval or rounded, which vary in diameter from the $\frac{1}{1000}$th to the $\frac{1}{240}$th of an inch. Each grain contains starch in two forms,—one, receiving the name *granulose*, is easily soluble, and gives a deep blue colour on the addition of iodine; the other form, *starch cellulose*, is less soluble, and gives a yellow or brown colour with iodine; but the former is most abundant in the grain. The individual grains either lie distinct from each other in the cells, as in the Potato, Wheat, and Pea, or they are aggregated so as to form compound grains, as in West Indian Arrowroot, obtained from Maranta arundinacea, and Portland Sago, procured from Arum maculatum. Grains of starch present a very characteristic concentrically striated appearance (fig. 27). This is the result of their mode of formation. The point round which the striæ are arranged is called the *hilum*. Starch is accumulated in the internal, and often in the subterranean parts of plants. It occurs abundantly in fleshy roots, and in stems, as well as in seeds and fruits, and is easily separated by washing. The ordinary cultivated grains yield starch in considerable quantity; so also do the Potato, Arrowroot, and Cassava plants, the Sago-palms, and Banana fruit. That procured from the Arrowroot plant consists of dull white grains; while that from the Potato, and from various species of Canna supplying tous-les-mois, is in the form of large shining particles. Sago and Tapioca are granulated forms of starch, the former being procured from the cells of various species of Sagus and Metroxylon, the latter from the Cassava plant. The existence of starch in the bark and young wood of trees, such as the Birch and Pine, renders them useful as articles of food in cold countries. Lichenin is a form of starch existing in the cells of Iceland moss and other lichens; while inulin, which occurs dissolved in the cell-sap, is the starchy matter supplied by the roots of the Dahlia, Dandelion, and Elecampane. By the action of prolonged heat, as well as by the addition of dilute sulphuric acid, or of malt, starch is converted into a soluble gummy substance called dextrin. The same change occurs during germination or the sprouting of the seed. Oily matters occur as drops in the interior of cells, usually associated with starchy substances or with albuminoids. These latter exist as small granules or large rounded masses with definite chemical and optical properties, and are termed *aleurone grains*. They are frequently associated with a crystalline arrangement of portions of the protoplasm of the cell known as *crystalloids*.

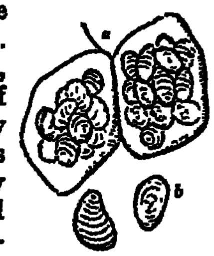

Fig. 27.

a, Starch cells of the Pea, showing grains of starch in the interior. *b*, Separate starch grains, with striæ and hilum.

Sugar. Sugar occurs abundantly in the sap of plants. When pure and in a solid state this substance is crystalline and soluble in water; but it also occurs in an uncrystallized form. There are two marked varieties of it. Cane-sugar, $C_{12}H_{22}O_{11}$, procured from the Sugar-cane, Sugar-maple, Beet, Carrot, &c.; and grape-sugar, occurring in numerous fruits, as Grapes, Gooseberries, Currants, Peaches, and Apricots The formula for grape-sugar is $C_6H_{12}O_6$. During the sprouting of the seed, starch is converted into grape-sugar, and a similar change is induced by the action of malt, or of any ferment. A sweet substance (not a true sugar), called Mannite, is procured from the Manna-ash (Ornus europæa) as well as from various sea-weeds, from species of Eucalyptus, and

Gum. from the Dandelion. Gum or mucilage is another substance found in vegetable tissues. When pure it is clear, soluble in water and also in dilute acids, but not soluble in alcohol or ether. It is one of the forms through which vegetable matter passes in being applied to the purposes of plant life. It exists largely in the vegetable juices. From the bark of many trees it is procured in the form of an exudation. Two well-marked kinds of gum are met with,—arabin, soluble in cold water, constituting the chief ingredient of gum-arabic, procured from various species of Acacia; and cerasin, insoluble in cold water, but readily soluble in boiling water, constituting the gummy secretion obtained from the Cherry and Plum. A substance called bassorin, or vegetable jelly, is found in Tragacanth, the roots of some Orchids, as well as in Carrageen (Chondrus crispus), and other sea-weeds. It is allied to gum, but differs in swelling up and becoming gelatinous when mixed with water. Another gum-like substance called pectin exists in the juice of the Apple, Pear, and other pulpy fruits. It is changed by the action of alkalies into pectic acid, which is found in many fruits and such succulent roots as Carrot, Turnip, Beet, &c. Oils, Fats, and Resins occur in Oils and resins.
cells of plants, or in special canals or glands as products of assimilation. The oils are either fixed or volatile,—the former being divided into drying, fatty, and solid, while the latter are distinguished according as they consist of carbon and hydrogen alone, or of these elements combined with oxygen or with sulphur. Resinous matter occurs in the form either of fluid balsams, or of the various kinds of solid resin and pitch. In the rind of the Orange and Lemon glands of oil occur (fig. 28). Turpentine canals are met with in the wood of Pines; and Vittæ, or oil-canals, in the fruit of Umbelliferous plants, such as the Coriander. In the fleshy covering of the fruit of the Olive there are numerous oil-cells. The fruit of the Guinea-palm yields a solid oil, called palm-oil. The dotted appearance of the leaves of the Orange, Myrtle, Eucalyptus, and St John's Wort, depends on the presence of numerous cells or cavities containing essential oil.

Fig. 31.—Cellular tissue from leaf of *Urostigma (Ficus) elasticum*. *c*, a large cell, *r*, cystolith, an agglomeration of crystals situated at the extremity of an inward prolongation of the cell-wall, *t*; *x*, cells filled with chlorophyll granules.

As allied to these secretions, we may notice caoutchouc, which is found in the milky juice of plants, especially those belonging to the Fig, Spurge, and Dogbane orders. The trees most prolific in this substance are Siphonia elastica, Urceola elastica, and Urostigma elasticum. Gutta-percha is the concrete milky juice of the Taban plant (Isonandra Gutta). Wax is also found in the tissues of plants, and it frequently occurs as a secretion on the stems, as in the Wax Palm, and on the surface of fruits, as in the bloom or glaucous secretion of the Plum and the Candleberry Myrtle. Crystals of lime salts occur in the interior of cells, and also in the cell-walls of plants. They

consist of lime in combination with carbonic or oxalic acids, and are in many plants very abundant. In Monocotyledons they usually assume the form of needle-like crystals, and are termed *raphides*; they consist of oxalate of lime (fig. 29). They are remarkably well seen in the Banana. The Squill bulb and the bulb of the Onion exhibit raphidian cells, which are easily separated during the decay of the plants. The crystals are also arranged in a conglomerate form (fig. 30), as may be seen in the root of Turkey Rhubarb, to which they impart grittiness; and in Old-Man-Cactus they constitute :0 to 80 per cent. of the dried tissue. In a single cell of the Poke (Phytolacca decandra) twenty to thirty crystals may be seen. In the epidermal cells of species of Ficus, and other allied plants, prolongations inward of the cell-wall occur, at the extremity of which small crystals of carbonate of lime are deposited (fig. 31); to these the name *cystoliths* has been applied. Siliceous matter occurs in the walls of cells, as in Grasses and Horsetails, and especially in Diatomaceæ.

2. *Integumentary System.*

A more or less marked division of the tissues into an outer layer bounding an inner mass is visible in all plants. Amongst the lower cellular plants this division is not very distinct; the circumferential cells are perhaps only a little smaller and more compacted than those near the centre. The higher cellular plants, however, exhibit great diversity.

mis. In them the cells of the circumference may be arranged in layers so as to constitute a true epidermis, the component cells having a definite relation to one another and to the exterior in the respective families. In all vascular plants an epidermis is found. In many cases, however, it is difficult to recognize it, as in the stems of submerged plants and in most roots. It usually consists of a single thin layer of cells closely compacted, and leaving no interspaces except at definite points (*stomata*), where openings lead into intercellular cavities. The cells composing this layer have their outer wall much thickened, the inner wall remaining thin, and they contain no starch or granular matter, and usually are colourless. In many aquatic plants, however, and in Ferns, chlorophyll is present. The apparent colour of the epidermis depends on that of the parenchymatous cells below, from which it can be separated as a colourless layer. Sometimes the cell-sap of the epidermal cells has a red tinge. The outer lamella of the outermost cell-wall of the epidermal cells usually becomes cuticular or corky, and thus is formed an external separable layer or *cuticle* upon the surface of the *epidermis proper*. This layer has different chemical properties from the epidermis, being insoluble in sulphuric acid. Upon this cuticle wax is frequently deposited in various forms, serving as a protective from moisture; of this nature is the bloom of the Plum. The cuticle in aquatic plants is very thin; in aerial plants it is much thicker. The single layer of cells forming the epidermis is not unfrequently strengthened by the addition to the inside of other layers of cells. In the leaves of Begonia, Ficus, and the outer covering (*velamen*) of the aerial roots of Orchids, this constitutes the *hypoderma*, the cells being of various forms. It is well seen also in vascular Cryptogams, many Bromeliaceæ, Ilex, &c. On those parts of the plant which live long and have vigorous growth in thickness the efficacy of the epidermis as a protective covering is increased by a large formation of cork. Each epidermal cell divides into an outer and an inner cell. The former at once becomes a cork cell, losing all its succulent matter; the latter remains capable of division. When a layer of these merismatic cells occurs we have a *cork cambium* or *phellogen*. If several layers of cork cells be formed a *cork tissue* or *periderm* is the result, which supersedes the epidermis, and which from variations in the several layers may be stratified. Not unfrequently the phellogen cells, in addition to giving off cork cells outwardly, give rise on the inner face to cells containing chlorophyll; and if a layer of such is formed it is termed a *phelloderm*. In such cases the phellogen lies between the phelloderm and the periderm. If phellogen lamellæ are formed deeper in the tissues of the plant, the internal layers of tissue become dry and constitute the bark. Periderm is thus replaced by bark. One Stomata.
important character of the epidermis is the presence of *stomata* or breathing-pores. These exist abundantly upon the stems and leaves of plants; they also occur on the parts of the flowers; but they are absent from all root structures, though present on underground axial structures. Each consists of a central pore bounded by two or more cells (guard-cells), which contain chlorophyll, starch, and matters distinct from the surrounding epidermal cells. The pore has various forms, and opens into an intercellular cavity (fig. 32). It may be round (Primrose), oval (Liliaceæ), quadrangular (Yucca). The arrangement of the stomata on the plant varies much. They may be in lines as in Equisetum, or they may be scattered irregularly as in Balsam (fig. 33), or in definite clusters as in Crassula and Saxifraga (fig. 34). In Equisetum the stomata, which are about $\frac{1}{250}$th of an inch in their greatest diameter, consist of four guard-cells; two of which are arched and thick at their outer convex margin, becoming thin at their inner c

FIG. 36.—Splitting of partition wall be (Sachs)

smaller cells overlie them, with their upper walls raised as ridges running at right angles to the stoma. This gives the stoma a fringed appearance, hence called pectinate. The mode of formation of a stoma is an interesting process, resulting from the division of a single epidermal cell. Preparatory to the complete formation of the mother-cell of the stomatic guard-cells, divisions may take place in the epidermal cells by which numerous or few cells are formed surrounding this mother-cell. In the mother-cell a partition wall is developed (fig. 35, *s*). A thickening of the partition wall occurs, and eventually in the central portion a fissure makes its appearance, which gradually increases in size (fig. 36). It does not, however, pass throughout the whole extent of the partition wall. An opening or stoma is thus formed, bounded on each side by a single guard-cell, leading into an intercellular space in the parenchyma beneath. If we suppose the mother-cell to be divided by numerous vertical septa we should have a stoma surrounded by many guard-cells, as occurs in some Hepaticæ; and in this family, after the formation of the fissure a series of horizontal septa appear in the guard-cell, and thus the stomatic opening becomes a canal. In Ceratopteris thalictroides the stoma is bounded by three cells,—two of which, in their open condition, are crescentic and concave inwardly, while the third surrounds them, except for a small space at the end of the long axis of the stoma, and has on this account been called *peristomatic*. In Urostigma elasticum four cells form the stoma. Subsequent changes in the surrounding epidermal cells may cause alterations in their relations to the stomata. Thus, in the Oleander (fig. 37) the epidermis

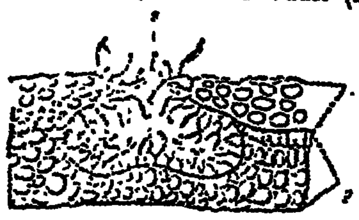

Fig. 37.

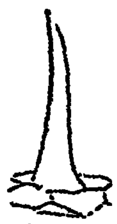

Fig. 38.

the Rice-paper plant (Fatsia papyrifera). When stellate hairs are flattened out, so as to form a sort of membranous expansion (fig. 44), a *scale* or *scurf* is produced. In Bromeliaceæ the scurfiness of the leaves is a marked character. To such expansions of the epidermis the name *lepis* is applied, and the surface is said to be *lepidote*. These scales have sometimes a beautiful silvery appearance, as in Elæagnus and Sea-buckthorn (fig. 44). Surrounding the base of the leaves of Ferns a brown chaffy substance occurs, consisting of elongated cells, to which the name of *ramentaceous hairs*, or *ramenta*, has been given. In Palms also a similar substance but of a fibrous texture occurs, called *reticulum* or *mattulla*. *Setæ* are bristles or stiff hairs, and the surfaces on which they occur are said to be *setose* or *setaceous*. Some hairs, as those of Drosera

(Sundew), have one or more spiral fibres in their interior. When the cells of hairs are hardened by thickening of the cell-wall, as in the Rose and Bramble, they are called Prickles (*aculei*). By some these are not considered as hairs, but are termed *emergencies*, inasmuch as they arise from a collection of cells, not from one epidermal cell. Various names have been given to the different forms of hairs. They are *clavate*, or *club-shaped*, gradually expanding from the base to their apex; *capitate* (fig. 42), having a distinct rounded head; *rough* or *scabrous*, with slight projections on their surface; *hooked* or *uncinate*, with a hook at their apex pointing downwards and to one side; *barbed* or *glochidiate*, with two or more hooks around the apex; *shield-like* or *peltate*, when attached by their middle, and projecting horizontally on either side, as in Malpighia urens (fig. 45), and in many Cruciferous plants; *cilia*, when surrounding the margin of leaves. On the pod of the Cowitch (Mucuna pruriens) hairs are produced with projections on their surface, which cause irritation of the skin. In Venus's Fly-trap (Dionæa muscipula) stiff hairs exist on the blades of the leaf (fig. 46), which, when touched, induce their closure.

Hairs occur on various parts of plants,—on the stem, leaves, flowers, seed-vessels, and seeds, and even in the interior of vessels. In the interior of the spathe of some Palms numerous ovate cells, analogous with hairs, occur in clusters, and can, when the spathe is dried, be shaken out in the form of powder. Cotton consists of the hairs surrounding the seeds of Gossypium herbaceum and other species of the genus. These when fresh are elongated tubular cells; when dried their walls collapse and they appear twisted. Hairs are occasionally developed to a great extent on plants exposed to elevated temperatures, as well as on those growing at high altitudes. When they occur on the organs of reproduction they are connected with fertilization, as the hairs on the style of Goldfussia, and the retractile hairs on the style of Campanula.

Different organs of plants are transformed into hairs,—as may be seen in the flowering stalks of the Wig-tree (Rhus Cotinus), and in the calyx of Compositæ.

Names are given to the surfaces of plants according to the presence or absence of hairs, as well as the nature of the hairs which cover them. The following are the more important terms;—*Glabrous*, smooth, having no hairs; *hairy* or *pilose*, furnished with hairs; *pubescent*, covered with soft, short, downy hairs; *villous*, having long, weak, often oblique hairs; *sericeous*, covered with long, closely appressed hairs, having a silky lustre; *hispid*, covered with long harsh or stiff hairs not appressed, *hirsute*, having long tolerably distinct hairs, not harsh nor appressed; *velvety* or *velutinous*, with a dense covering of short down, like velvet; *tomentose*, covered with crisp, rather rigid, entangled hairs like cotton, which form a sort of felt (*tomentum*); *woolly*, with long curled and matted hairs like wool; *bearded* or *stupose*, when hairs occur in small tufts. The hairs which are most frequently met with in plants are called *lymphatic*, from their not being connected with any peculiar secretion. Those, on the other hand, which have secreting cells at their base (fig. 43) or apex, are denominated *glandular*, and are not to be distinguished from glands. On young roots cellular projections occur, which may be called *radical* hairs. Young leaves and buds are frequently covered with protecting hairs. On the parts of the flower, as in the Iris, coloured hairs occur which have been called *corolline*.

In connection with the epidermal appendages we may notice glands, although they may occur in any tissue. A gland consists of a single cell or a collection of cells secreting substances different from those contained in the surrounding cells. In the former case the gland is simple, in the latter it is compound. In compound glands it frequently happens that the walls of the inner cells are absorbed, and thus the gland has only a single cavity, as in the glands of the Orange rind (fig. 28); these are termed *vesicular*. The secretion of the glands may be stored in their interior, as in Orange rind, and in the leaves of Laurus Camphora, or it may be exuded as in Lychnis viscaria, and in the nectaries of Fritillaria imperialis (fig. 50). Hairs serve as ducts through which the secretion of glands is discharged. Such hairs are seen in the Nettle (fig. 43), in Loasa or Chili Nettle, and in Malpighia (fig. 45), and are

FIG. 45.—Peltate hair *pp* of *Malpighia urens* rising from *e*, epidermis, *g*, gland.
FIG. 46.—Irritable leaves of Venus's Fly-trap (*Dionæa*)

commonly called stings (*stimuli*). In the Nettle they are formed of a single conical cell, dilated at its base, and closed at first at the apex by a small globular disk placed obliquely. This disk breaks off on the slightest touch, when the sharp extremity of the hair enters the skin, and pours into the wound the irritating fluid which has been pressed out from the elastic epidermal cells at the base. When a nettle is grasped with violence, the sting is crushed, and hence no injury is done to the skin. The glandular enlarged apex of hairs sometimes exudes a viscid secretion, as in the Chinese Primrose and in the Sundew. The hairs of the latter plant, by this secretion, detain insects which happen to alight on them. The hairs gradually close on the insects, electrical phenomena taking place during the movement, and then the secretion from the glands becoming acid, an action takes place upon the organic matter analogous to that of the pepsin of the gastric juice, by which it is rendered soluble, and is eventually absorbed by the plant. A similar property is possessed by the secretion from the glands upon the surface of the leaf of Venus's Fly-trap (Dionæa muscipula, fig. 46). The acid in both instances belongs to the formic acid series. Glands may be either internal or external, and they may be situated at the extremity of a hair (when they are *stalked*), or they may be immersed in the substance of the plant (*sessile*). In the Dittany (Dictamnus albus, fig. 47) a form of gland is seen intermediate between the sessile and stalked form. The glands in this plant secrete a green oily matter, so also do the stalked glands in the Rose. In the Ice-plant the glands appear as elevations of the epidermis, containing a transparent fluid like ice, which is said to have an alkaline reaction; in the Chick-pea similar superficial cells contain an acid fluid. Clear glands are also seen on the under surface of the leaf of Passiflora lunata. Resinous glands are seen in the Hop (fig. 48) and Hemp plants. At the base of the petals of the Crown-imperial (fig. 50), cavities occur containing a honey-like fluid, secreted by what are called *nectariferous* glands.

FIG. 50.—One of the petals of *Fritillaria imperialis*, Crown Imperial, showing a pit or depression *g* at the base containing a honey-like secretion. This gland is sometimes called a nectary.

Cavities containing saccharine matter, surrounded by small thin-walled cells, are met with in the leaves of Acacia longifolia, also in Viburnum Tinus, and Clerodendron fragrans. The cavities communicate with the surface of the leaves by means of canals. Peculiar sessile glands secreting a gummy substance are found at the inner side of the base of the petioles of Cinchona and Ipecacuan plants (fig. 49). On the buds of various trees peculiar glandular hairs termed *colleters* exist, secreting a gummy mucilaginous matter, the *blastocolla*, which covers the bud. These, however, disappear on the bursting of the bud. They

seem to have a protective function. The secretions of glands are very various, oily, waxy, resinous, gummy, saccharine, acid, &c.

ORGANS OF PLANTS.

Having now considered the elementary structures and tissues found in the Vegetable Kingdom, we proceed to view them in combination to form the plant. The simplest plant is found amongst Algæ, where, as in the Red-snow plant (Protococcus nivalis, fig. 51) the whole organism consists of a single isolated cell. Other Algæ and all Fungi and Musci are composed of a number of cells united in various ways; whilst in Ferns and their allies and all flowering plants vessels are formed in addition to the cells. The plants in which the tissues are entirely cellular are termed *cellular* plants; those in which vessels are also found are *vascular* plants.

Fig. 51.

Cells of the Red-snow plant (*Protococcus nivalis*), in different stages of growth and development. *a*, cell in the young state; *b*, cell fully formed, with cellules in its interior ready to be discharged, and to form independent plants; *c*, cell after its contents have been discharged.

That the portions of a plant may be properly maintained two functions have to be performed, namely, *nutrition*, on the proper performance of which the life of the individual plant depends, and *reproduction*, by which the perpetuation of the type is provided for. In such a simple form as the Red-snow plant (fig. 51) those functions are performed by the single cell. In the plants composed of numerous cells a differentiation takes place by which special cells are set apart for particular functions, and thus certain organs are formed in the plant. In the higher plants those organs become more complicated from the introduction of the vascular element.

The nutritive organs of plants are generally known as the *root*, the *stem*, and the *leaves*. In all vascular plants and the higher cellular plants an axis or stem having roots and bearing leaves is distinguishable, and such plants have been designated *Cormophytes* or *Phyllophytes*. In the lower class of cellular plants, as Fungi and Algæ, no such distinction is possible, and there is merely a flattened leafy expansion with dependent filiform processes; this structure has been termed a *thallus*, and such plants are *Thallogens* or *Thallophytes*.

Amongst the higher plants the reproductive organs are,

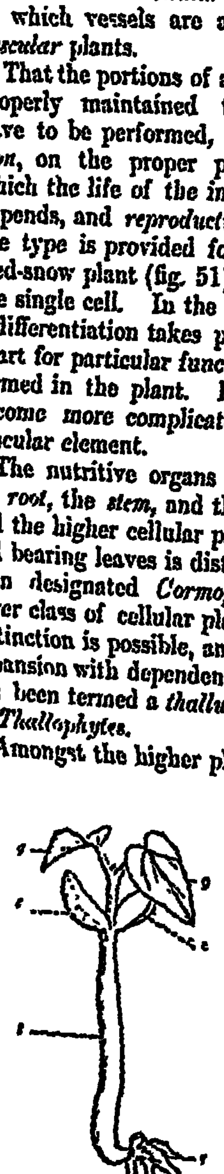

Fig. 52.

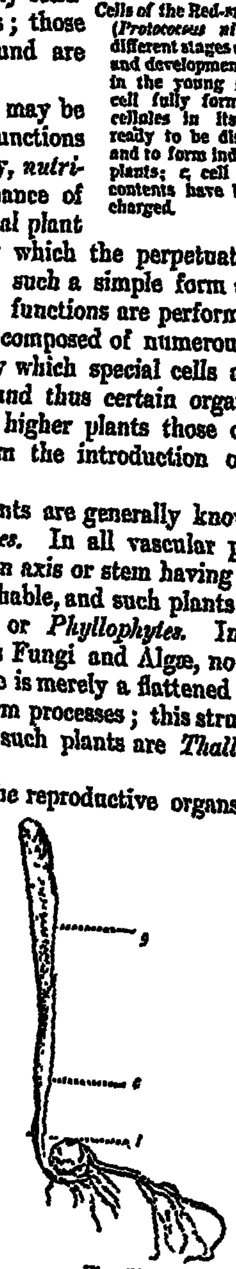

Fig. 53.

Fig. 52.—Haricot or French Bean, a Dicotyledonous plant, germinating. *r*, the roots coming off from the radicular end of the axis; *t*, the hypocotyledonary portion of the axis bearing the cotyledons *c*, *c*; the young stem and leaves, *g*, *g*.

in ordinary language, comprehended under the term flower; and, as they are conspicuous, such plants have been denominated *Flowering*, *Phanerogamous*, or *Phænogamous*. Amongst all cellular plants and in some vascular plants, as Ferns and Equisetum, there are no flowers, and the reproductive organs are inconspicuous, hence they have been termed *Flowerless* or *Cryptogamous*. In all cases the young plant, or embryo, is completely cellular. But as growth proceeds, that differentiation takes place which distinguishes the several classes of plants one from the other. In Phanerogams the first leaves produced upon the embryo plant are termed primary, seed-lobes, or *cotyledons*. In some cases these are two in number, and are opposite one another. Plants in which this occurs are *Dicotyledonous* (fig. 52), as our ordinary forest trees. In other plants the lobes alternate and only one cotyledon is formed; such are *Monocotyledonous* (fig. 53), as Grasses, Lilies. In Cryptogams, on the other hand, no such seed-lobes or cotyledons are produced, and they are *Acotyledonous* (fig. 54).

Primary tissue.

In all plants the original cell tissue which gives origin to its parts is of a uniform nature, and is termed the *primary tissue*. When all the cells of this tissue are capable of multiplication and division the tissue is a *meristem* or *generating tissue*. If the cells are not so capable, then it is a *permanent tissue*. The primary tissue at the growing point of any shoot or root is essentially a meristem, and it has been designated the *primary meristem* to distinguish it from the *secondary meristem*, which is applied to a tissue in the older parts of a stem or root which remains or becomes capable of division. The growing point of the apex has been termed the *punctum vegetationis*, and it not unfrequently forms a conical projection, and is then the *vegetative cone*. By growth at this punctum vegetationis the shoot or root increases in length, and the mode of addition is in many cases of a definite character. Two chief types of growth are recognized. In one of these a single large cell is always present at the apex, termed the *apical cell*, which may be regarded as the mother-cell, whence by bipartition in a definite manner the whole meristem below it has arisen, as is well seen in vascular Cryptogams and cellular plants. The other type is seen in Phanerogams, and here no such apical cell is visible, but a number of cells are found at the apex by whose multiplication the subsequent tissues are formed. But in whatever way formed, a primary meristem is the result of all the processes of growth, and by differentiation of its cells the various parts of the shoot or root are formed. The outer layer of the primary meristem, which extends completely over the punctum vegetationis, is termed the *dermatogen*; it is the primordial epidermis, being continuous with the epidermis of the shoot and afterwards becoming epidermis. Underneath the dermatogen several layers of cells are distinguished, continuous with the cortical portion of the shoot or root; this is the primordial cortex, and constitutes the *periblem*. Enclosed by this is a central cellular mass, out of which the fibro-vascular bundles and the structures of the central part of the shoot or root are formed; this has been termed the *plerome*. If the growing axis be a young root there is in addition developed, usually from the dermatogen, a mass of cells at the extremity, constituting a *root-cap*, or protective covering, to the delicate meristematic cells beneath; no such structure is formed in a stem. Thus a stem is structurally distinct from a root in having no root-cap.

In the plerome the fibro-vascular bundles are formed. Certain cells become elongated and prosenchymatous and united in bundles leaving no intercellular spaces; Fibro-vascular bundles.

this mass is termed the *procambium* of the fibro-vascular bundle. As growth proceeds changes take place in the cells by thickening, and, their contents disappearing, various kinds of cells and vessels are formed. In this way the whole mass of the procambium may be converted into permanent tissue, and then growth ceases; or an inner portion of the bundle remains merismatic, which is called the *cambium*, and then growth proceeds, the shoot or root increasing in thickness by the cambium forming new cells on both sides In the former case the bundle is *closed*, as in Cryptogams and Monocotyledons and some Dicotyledons; in the latter it is *open*, as in most Dicotyledons and Conifers. In every fibro-vascular bundle a separation into two groups of structures may be distinguished—the wood or xylem layers; and the bast or phloëm layers. As long as the bundle is open and cambium present, these layers are separated by the cambium (fig. 55). Their

varies. In some cases the phloëm is nearer the circumference, in other instances the xylem is peripheral, and in rare cases amongst Dicotyledons there are phloëm layers both on the outer and inner sides of the fibro-vascular bundles. In vascular Cryptogams the phloëm layers always surround the xylem portion of the bundle.

In the xylem or wood portion of a fibro-vascular bundle the cells all tend to thicken their walls, and, consequently, numerous kinds of cells and vessels are found, which are usually arranged in a definite manner. On the side furthest removed from the phloëm we find spiral vessels interspersed with wood-cells (figs. 55 and 56), outside are reticulated and scalariform vessels, and then interspersed with wood cells are large pitted vessels. In the phloem or bast layers the cells have not such a tendency to thicken, but usually remain thin-walled, forming ordinary parenchymatous cells, or becoming perforated and forming sieve cells. In certain layers, however, the cell-walls are thickened so as to become flexible, constituting the bast fibres. Around every fibro-vascular bundle a single layer of cells of the fundamental cellular tissue of the stem is marked off from its surroundings, the cells get filled with starch-grains, and this constitutes what has been termed the *bundle sheath* or starch-bearing layer (fig. 57). In fig. 57 is seen a transverse section of the closed fibro-vascular bundle from the Maize, and it will be observed that it is essentially the same as that of the open bundle (fig. 55), only that all the cambium cells have passed into permanent tissue.

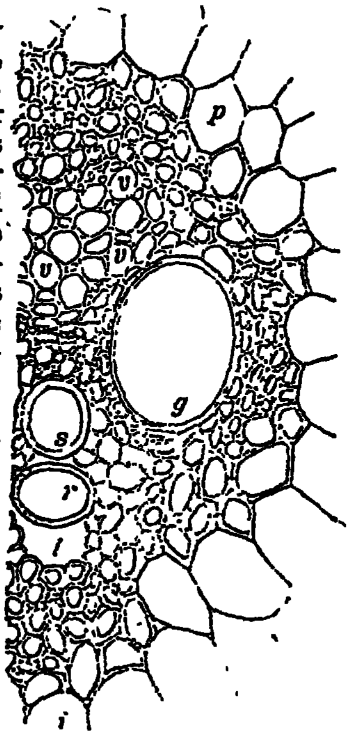

Fig. 57.

Between *r* and *s* are reticulated vessels. *p*, surrounding parenchyma. Outer cells *a* of the bundle are parenchymatous, *i* marks the inner side of the bundle. (*Sachs.*)

In all plants a provision is made for branching of the various organs, and two principal forms of it may be recognized. In one of these the generating axis elongates at the apex, producing in succession lateral structures. To this form the term *monopodium* has been applied. In the second form there is a cessation of growth at the apex in the direction of previous elongation of the axis, and a continuance in two diverging directions. This is *dichotomous* branching. In their rudimentary state all branchings may be easily referred to one or other of those types; but in the mature system it is frequently difficult to recognize the type, owing to irregular development of the successive branching. Thus in a dichotomous branching only one of the secondary axes may develop strongly, the weaker branch appearing as a small lateral shoot from its base, and an apparent primary shoot is thus produced which in reality consists of the bases of single branches of consecutive forkings. Such an axis is termed a *pseudaxis* or *sympodium*. And, again, in monopodial branchings the primary axis may continue to develop more strongly than its lateral axes, which in their turn develop similarly, and a *racemose* form arises; or the primary axis may be arrested in growth, and the secondary axes develop more strongly and overtop it, when a *cymose* branching results. More will be said on this subject when considering the inflorescence of Phanerogams, in which the various forms of branching are well seen.

We now proceed to consider the form and internal structure of the various organs of plants.

I. ORGANS OF NUTRITION.

1. *Root or Descending Axis.*

ot. Speaking generally, the root is that portion of the plant which descends into the soil. In all plants the root is at first entirely cellular. It may remain permanently so, or vessels may be formed in it. The *Radicle*, or young root (fig. 58, *r*), is the first portion of the embryo protruded from the seed or spore (fig. 54) when germination commences, and resembles very much in structure the young stem. Both are entirely cellular, consisting of a central nucleus of cellular tissue covered by two or more layers of cells. But at the apex of the root a mass of cells is developed, which constitutes what is known as the root-cap or *pileorhiza*. These cells extend for some distance along the sides of the root, forming a sheath, and in some cases, as Lemna, the cap becomes loosened from the root, remaining attached by a few cells at the apex only, and then it is known as the *ampulla*. This root-cap distinguishes structurally the root from the stem, and it serves as a protection to the apical growing-point of the root. The roots of Thallophytes, consisting entirely of cells, do not develop a root-cap.

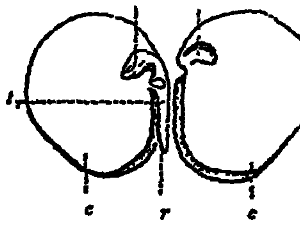

Fig. 58.

The dicotyledonous embryo of the Pea laid open. *c*, *c*, the two fleshy cotyledons, or seed-lobes, which remain under ground when the plant sprouts; *r*, the radicular extremity of the axis whence the root arises; *t*, the axis bearing the young stalk and leaves *g*, which lie in a depression of the cotyledons *f*.

The root is merely a prolongation downwards of the stem, and the part where they unite is the *collum* or *neck*. Afterwards the root is distinguished from the stem by the absence of a provision for the development of leaf-buds. It is not always easy to distinguish between a stem and a root. Many so-called roots bear at their upper part a portion called their *crown*, whence leaf-buds arise. Underground stems and roots are often confounded. Some plants, as the Moutan Pæony, the Plum-tree, Pyrus japonica, and especially Anemone japonica, have a power of forming buds on what are commonly called their roots. The last-mentioned plant develops these buds on every part of its extensively ramifying root-like prolongations, which may be chopped into numerous pieces, each capable of giving rise to a new plant. Such is also the case with the annulated root of Ipecacuan. Roots are usually subterranean and colourless. Externally, they have a cellular epidermal covering of a delicate texture, sometimes called *epiblema*, in which no stomata exist. In woody plants fibro-vascular bundles are found in the roots, and there is an internal arrangement of tissues similar to that seen in the stem itself, but spiral vessels are rare in the root. The axis of the root gives off branches which divide into radicles or fibrils, the extremities of which, composed of delicate cellular tissue constituting the *punctum vegetationis*, have been erroneously called *spongioles* or *spongelets*; they are not distinct organs. Hairs are often seen on roots, but no true leaves. These hairs consist of simple elongated cells, which occur singly, and appear to serve the purpose of absorption. Roots increase principally by additions to their extremities, which are constantly renewed, so that the minute fibrils serve only a temporary purpose, and represent deciduous leaves; but in large trees which form thick roots an increase in diameter occurs in the root similar to what is seen in the stem itself. In some plants no roots are formed at all, thus in the Orchidaceous plants Epipogium Gmelini and Corallorhiza innata, and also in Lemna arrhiza, no roots occur. Roots may be given off from any portion of a stem, originating as cellular prolongations from the inner portion of the stem, and coming off at any point of the stem, or at small lenticular points to which the name of *lenticels* has been given by some. When the stem is more or less horizontal the roots given off from it pass directly into the soil; but if the stem be erect they pass for a certain distance downwards through the air, and are called *aerial*. The latter are well seen in the Screw-pine (Pandanus), the Banyan (Ficus indica, fig. 59), and

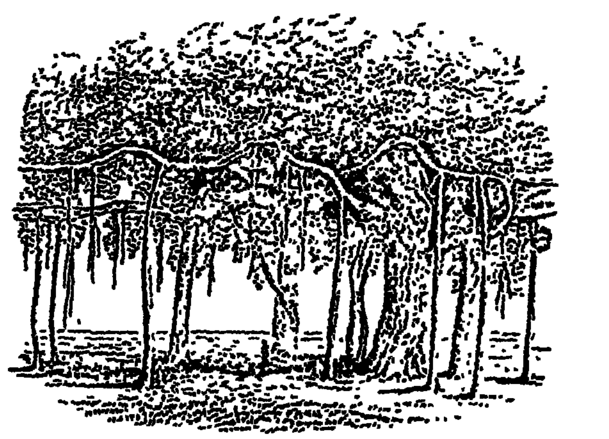

Fig. 59.

Ficus indica, the Banyan tree, sending out numerous aerial roots, which reach the soil, and prop the branches.

many other species of Ficus, where they assist in supporting the stem and branches. In the Mangrove they often form the entire support of the stem, which has decayed at its lower part. In Tree-ferns they form a dense coating around, and completely concealing, the stem; such is also the case in some Dracænas and Palms. In *Epiphytes*, or plants growing in the air, attached to the trunks of trees, such as Orchids of warm climates, the aerial roots produced do not reach the soil; they continue always aerial and greenish, and they possess stomata. Delicate hairs are often seen on these epiphytal roots, as well as a peculiar investment formed by the cells of the epidermis which have lost their succulent contents and are now filled with air. This layer is called *velamen radicum*, or covering of the roots. The aerial roots of the Ivy are not the nutritive roots of the plant, but are only intended for mechanical support.

Parasitic plants, as the Mistleto (Viscum), Broom-rape (Orobanche), and Rafflesia, send root-like processes into the substance of the plants whence they derive nourishment. In the Dodder (Cuscuta), the tissue around the roots swells into a kind of sucker (*haustorium*), which is applied flat Plate X.
upon the other plant, and ultimately becomes concave, so as to attach the plant by a vacuum. From the bottom of the sucker the root protrudes, which penetrates the supporting body. In the case of parasitic Fungi, such as Mould, there are cellular filaments which spread among the tissues of plants, and which may be looked upon as equivalent to roots and stems united. They form the *spawn* or *mycelium* of these plants, and in some cases cause rapid destruction of the tissues of plants, as in the disease called Dry-rot.

The forms of roots depend upon the mode in which the axis descends and branches. The mode of branching of roots is almost universally monopodial, only in Lycopodiaceæ is it dichotomous. When the central axis goes deep into the ground in a tapering manner, without dividing, a *tap-root* is produced. This kind of root is sometimes shortened, and becomes succulent, forming the *conical* root of Carrot, or the *fusiform* or spindle-shaped root of Radish, or the *napiform* root of Turnip. In ordinary forest trees the first root protruded continues to elongate and forms a long

primary root-axis, whence secondary axes come off. In other plants, especially Monocotyledons, the primary axis soon dies and the secondary axes take its place. When the descending axis is very short, and at once divides into thin, nearly equal, fibrils, the root is called *fibrous*, as in many Grasses (fig. 60); when the fibrils are thick and succulent the root is *fasciculated*, as in Ranunculus Ficaria,
VII. Asphodelus luteus, and Œnanthe crocata; when some of the fibrils are developed in the form of tubercules,

Fig. 60.

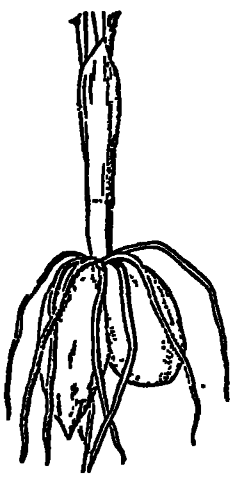

Fig. 61.

Fig. 62.

FIG. 60.—Fibrous root of a Grass. Numerous fibrils coming off from one point.
FIG. 61.—Orchis, showing tubercules or tuberous roots, which contain a gummy matter called bassorin.
FIG 62.—An epiphytic Orchid with pseudo-bulbs.

the root is *tubercular*, as in Orchis (fig. 61); when the fibrils enlarge in certain parts only, the root is *nodulose*, as in Spiræa Filipendula, or *moniliform*, as in Pelargonium triste, or *annulated*, as in Ipecacuan. Some of these so-called roots are formed of a stem and root combined, and when cut in pieces they give rise to buds and new plants. In some cultivated plants, as Turnip, the central root is sometimes injured, so as to end abruptly, and it then divides into numerous branches, resembling a fasciculated root. This gives rise to the disease called Fingers and Toes, which is very injurious to the crop. Anbury is a disease where a clubbing of the root takes place. The mode in which the fibres of roots are produced and developed gives origin to different forms of rhizotaxis, or root-arrangement.

Roots either fix the plant in the soil or attach it to other bodies. They absorb nourishment by a process of imbibition or endosmose through their cellular extremities. The elongation of the roots by their extremities enables them to accommodate themselves to the soil, and allows the extremities of the rootlets to extend deeply without being injured. Roots, in their lateral extension, bear usually a relation to the horizontal spreading of the branches, so as to fix the plant firmly, and to allow fluid nutritive substances to reach the absorbing extremities. As has been already stated, the structure of perennial roots is identical with that of the stem. Thus in Dicotyledons we find a pith, medullary rays, zones of wood, cambium layers, and bark, although no medullary sheath is present. In Monocotyledons we have fibro-vascular bundles distributed in a matrix of cellular tissue. The young primary root in Monocotyledons differs from that in Dicotyledons in that it rises deeply within the embryonal tissue, and on germination this tissue is ruptured and forms a sheath, around the base of the roots, called *coleorhiza*. Amongst Monocotyledons the primary roots usually soon die, and secondary roots are formed in abundance. In vascular Dicotyledonous plants the structure of the root is similar to that of the stem. In Thallogens the roots consist merely of simple or branching filamentous hair-like structures. In some large tropical Seaweeds the root-like bodies develop to a large extent, but serve only as fixing organs, and take no share in nourishing the plant.

2. *Stem or Ascending Axis.*

A stem may be defined as an axis bearing leaves. Stem.
Structurally it differs from a root in having no development of cells forming a cap over the growing point. Under the term *caulome* (stem structure) are included all those parts of a plant morphologically equivalent in bearing leaves. The stem generally ascends, seeking air and light, and has therefore been termed the *ascending axis*. Stems have usually considerable firmness and solidity, but sometimes they are weak, and either lie prostrate on the ground, thus becoming *procumbent*, or climb on plants and rocks by means of rootlets, like the Ivy, being then called *scandent*, or twist round other plants in a spiral manner like Woodbine, when they are *volubile*. Twining plants turn either from right to left, as the French Bean, Convolvulus, Passion-flower, Dodder, Periploca, and Gourd; or from left to right Plate X.
as Honeysuckle, Twining Polygonum, Hop, and Tamus. Bryony tendrils twine from right to left, and left to right, alternately. In warm climates twining plants (*lianas*) often form thick woody stems; while in temperate regions they are generally herbaceous. Exceptions, however, occur in the case of the Clematis, Honeysuckle, and Vine; the twining stem of the vine has been called *sarmentum*. Some stems are developed more in diameter than in height, and present a peculiar shortened and thickened aspect, as Testudinaria or Tortoise-plant, Cyclamen, Melocactus, Echinocactus, and other Cactaceæ; while in many Orchids (fig. 62) the stem assumes an oval or rounded form, and is called a *pseudo-bulb*.

Names are given to plants, according to the nature and duration of their stems. *Herbs*, or *herbaceous* plants, have stems which die down annually. In some of them the whole plant perishes after flowering; in others, the lower part of the stem forming the *crown of the root* remains, bearing buds from which the stem arises next season. In what are called *biennial* herbs, the whole plant perishes after two years, while in *perennial* herbs the crown is capable of producing stems for many years, or new annual products are repeatedly added many times, if not indefinitely, to the old stems. The short permanent stem of herbaceous plants is covered partially or completely by the soil, so as to protect the buds. Plants producing permanent woody stems are called *trees* and *shrubs*. The latter are less than five times the height of a man, and produce branches from or near the ground; while the former have conspicuous trunks, which attain at least five times the height of a man. Shrubby plants of small stature are called *under-shrubs* or *bushes*. The limits between these different kinds of stem are not always well defined; and there are some plants occupying an intermediate position between shrubs and trees, to which the name of *arborescent* shrubs is occasionally given. The stem receives the name of *caulis* in ordinary herbaceous plants which do not form a woody stem, *culm* in grasses, *truncus* in trees, *caudex* or *stock* in Palms and in some Cacti, and *stipe* in Ferns. The term *haulm* is probably a corruption of culm; it is used by farmers to designate the stem of grasses and the herbaceous stems of plants. The stem is not always conspicuous. Plants with a distinct stem are called *caulescent*; those in which it is inconspicuous are *acaulescent*, as the Primrose, Cowslip, Gentian, and Dandelion. A similar term is given in ordinary language to plants whose stems are buried in the soil, such as Cyclamen or Sowbread. Some plants are truly stemless, and consist only of expansions of cellular tissue representing stem and leaf, called a *thallus*, and hence are denominated *Thallogens*, or *Thallophytes*.

Stems have a provision for a symmetrical arrangement [illegible]

of leaves and branches,—*nodes*, or points whence leaf-buds are produced, being placed at regular intervals. No such provision occurs in roots. The intervals between nodes are called *internodes*. The stem, although it has a tendency to rise upwards when first developed, in many instances becomes prostrate, and either lies along the ground partially covered by the soil, or runs completely underneath its surface, giving off roots from one side and buds from the other. Some stems are therefore subterranean, and are distinguished from roots by the provision made for regular leaf-buds. The first rudiment of the young stem in the embryo appears outside the seed or spore after the radicle has been protruded. It is termed the *plumule* (fig. 58), and differs from the radicle in the absence of a root-cap and in its tendency to ascend. The apical growing portion of the young stem constitutes the terminal bud of the plant, and by its development the stem increases in height; but in addition there is a provision for the production of lateral buds, which develop into lateral shoots more or less resembling the parent stem, and by these the branching of the plant is determined. These buds are found in the *axil* of previously-formed leaves; or, in other words, in the angle formed between the stem and leaf. They are hence called *axillary*. They are produced always from the outer portion of the stem except in the case of Equisetaceæ (Horsetails), where they have a deep-seated origin. At first they consist entirely of cellular tissue, but in the progress of growth vascular bundles are formed in them continuous with those of the stem, and ultimately branches are produced, which in every respect resemble the axis whence the buds first sprang. As the axis of the bud increases in length, cellular projections appear at regular intervals upon the primary meristem, which are the rudimentary leaves.

Buds, as has been stated, are either terminal or lateral. By the production of the former, stems increase in length, while the latter give rise to *branches* (*rami*), from which others, called *branchlets* or *twigs* (*ramuli*), arise, and add to the diameter of the stem. The terminal bud, after producing leaves, sometimes dies at the end of one season, and the whole plant, as in annuals, perishes; or part of the axis is persistent, and remains for two or more years, each of the leaves before its decay producing a bud in its axil. This bud continues the growth in spring. In ordinary trees, in which there is provision made for the formation of numerous lateral buds, any injury done to a few branches is easily repaired; but in Palms, which only form terminal buds, and have no provision for a lateral formation of them, an injury inflicted on the terminal bud is more likely to have a prejudicial effect on the future life of the plant. In the trees of temperate and cold climates the buds which are developed during one season lie dormant during the winter, ready to burst out under the genial warmth of spring. They are generally protected by external modified leaves in the form of *scales* (*tegmenta* or *perulæ*), which frequently exhibit a firmer and coarser texture than the leaves themselves. They serve a temporary purpose, and usually fall off sooner or later, after the leaves are expanded. The bud is often protected by a coating of resinous matter, as in the Horse-chestnut and Balsam Poplar, or by a thick downy covering, as in the Willow. Linnæus called leaf-buds *hibernacula*, or the *winter quarters* of the young branch. In some plants, as in Platanus, the buds destined to live through the winter are so completely surrounded by the base of the petiole as not to be visible until the leaf has fallen off. These are said to be *intrapetiolar*.

In the bud of a common tree, as the Sycamore (fig. 63), there is seen the cicatrix left by the leaf of the previous year *c*, with the pulvinus or swelling *p*, then the scales *e*, *e*, arranged alternately in a spiral, and overlying each other in what is called an *imbricated* manner. On making a transverse section of the bud (fig. 64), the

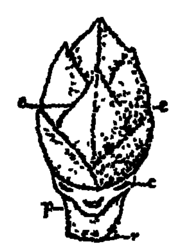

Fig. 63.

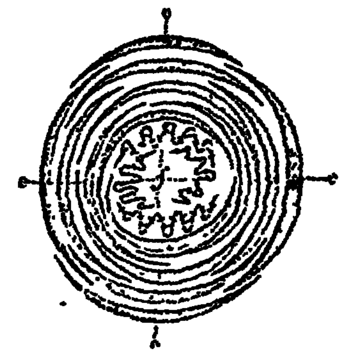

Fig. 64.

FIG. 63.—Leaf-bud of Sycamore (*Acer Pseudo-platanus*) covered with scales.
FIG. 64.—Transverse section of the same leaf-bud.

overlying scales *e*, *e*, *e*, *e*, are distinctly seen surrounding the leaves *f*, which are plaited or folded round the axis or growing-point. In plants of warm climates the buds are often formed by the ordinary leaves without any protecting appendages; such buds are called *naked*. A bud may be removed in a young state from one plant and grafted upon another by the process of *budding*, so as to continue to form its different parts; and it may even be made to grow in the soil, in some instances, immediately after removal. In some trees of warm climates, as Cycas, Plates XV.
Papaw-tree, Palms, and Tree-ferns, growth by terminal and VI.
buds is well seen. In these plants the elongation of the stem is generally regular and uniform, so that the age of the plant may be estimated by its height; owing to this mode of growth they do not attain a great diameter. Although provision is made for the regular formation of buds, there are often great irregularities in consequence of many being abortive, or remaining in a dormant state. Such buds are called *latent*, and are capable of being developed in cases where the terminal bud, or any of the branches, have been injured or destroyed. In some instances, as in Firs, the latent buds follow a regular system of alternation; and in plants with opposite leaves, it frequently happens that the bud in the axil of one of the leaves only is developed, and the different buds so produced are situated alternately on opposite sides of the stem. Occasionally, after a partial development as branches, buds are arrested and form knots or nodules. The embryo-buds or nodules of the Beech, Cedar, and Olive are apparently of this nature.

When the terminal bud is injured or arrested in its growth the elongation of the main axis stops, and the lateral branches often acquire increased activity. By continually cutting off the terminal buds, a woody plant is made to assume a bushy appearance, and thus *pollard* trees are produced. Pruning has the effect of checking the growth of terminal buds, and of causing lateral ones to push forth. The peculiar bird-nest appearance, often presented by the branches of the common Birch, depends on an arrestment in the terminal buds, a shortening of the internodes, and a consequent clustering or fasciculation of the twigs. In some plants there is a natural arrestment of the main axis after a certain time, giving rise to peculiar shortened stems. Thus the crown of the root is a stem of this nature, forming buds and roots. Such is also the case in the stem of Cyclamen, Testudinaria Elephantipes, and in the tuber of the Potato. The production of lateral in place of terminal buds sometimes gives the stem a remarkable zigzag aspect. Branches are sometimes arrested in their progress at an early stage of their development, and do not appear beyond the surface of the stem; at other times, after having grown to a considerable size, they undergo decay. In both instances the lower part of the

branch becomes embedded and hardened among the woody layers of the stem.

ıches. The mode in which branches come off from the stems gives rise to various forms of trees, as pyramidal, spreading, or weeping,—the angles being more or less acute or obtuse. In the Italian Poplar and Cypress the branches are erect, forming acute angles with the upper part of the stem; in the Oak and Cedar they are spreading or patent, forming nearly a right angle; in the Weeping Ash and Elm they come off at an obtuse angle; while in the Weeping Willow and Birch they are pendulous from their flexibility. The comparative length of the upper and under branches also gives rise to differences in the contour of trees, as seen in the conical form of Spruce, and the umbrella-like form of the Italian Pine (*Pinus Pinea*). The branching of some trees is peculiar. In the Amazon district many Myristicaceæ and Monimiaceæ have verticillate branches coming off in fives. This is also seen in the Chili Pine. Some Amazon trees taper downwards, so as to have a form like an inverted cone or pyramid, as in the Mulatto tree (Eukylista Spruceana), one of the Cinchonaceæ.

Branches are sometimes long and slender, and run along the ground, producing buds with roots and leaves at their extremity or apex. This is seen in the *runner* (*flagellum*) of the Strawberry. In the Houseleek (Sempervivum) there is a similar prostrate branch of a shorter and thicker nature, producing a bud at its extremity capable of independent existence. It receives the name of *offset* (*propagulum*). In many instances the branch decays, and the young plant assumes a separate existence. Gardeners propagate plants by the process of *layering*, which consists in bending a twig, fixing the central part of it into the ground, and, after the production of roots, cutting off its connection with the parent. A *stolon* differs from these in being a branch which curves towards the ground, and, on reaching a moist spot, takes root and forms an upright stem, and ultimately a separate plant. This is a sort of natural layering, and the plant producing such branches is called *stoloniferous*. In the Rose and Mint a subterranean branch arises from the stem, which runs horizontally to a certain extent, and ultimately sends up an aerial stem, which becomes an independent plant. Such branches are denominated *suckers*, and the plants are *surculose*. The gardener divides the connection between the sucker and the parent stem, in order to propagate these plants. In the case of Asparagus and other plants which have a perennial stem below ground, subterranean buds are annually produced, which appear above ground as shoots or branches covered with scales at first, and ultimately with true leaves. The young shoot is called a *turio*. These branches are herbaceous and perish annually, while the true stem remains below ground ready to send up fresh shoots next season. In Bananas and Plantains the apparent aerial stem is a shoot or leaf-bud sent up by an underground stem, and perishes after ripening fruit. Branches are sometimes arrested in their development, and, in place of forming leaves, become transformed into *spines* or *thorns*, as in the Hawthorn. Plants which have spines in a wild state, as the Apple and Pear, often lose them when cultivated, in consequence of their being changed into branches; in some cases, as in the Sloe (Prunus spinosa), (fig. 65), a branch bears leaves at its lower portion, and terminates in a spine. Plants bearing thorns (modifications of branches or leaves) are denominated *spiny*, *spinose*, or *spinescent*. A bud is sometimes developed as a slender spiral or twisted branch, called a *tendril* or *cirrus*. In the Passion-flower the lateral buds are thus altered, with the view of enabling the plant to climb. In the Vine the tendrils are looked upon as the terminations of separate axes, or as transformed terminal buds, and are sometimes called *sarmenta*. In the Vine there are no young buds seen in the angle between the stem and leaves, nor between the stem and tendrils; and the latter are not axillary.

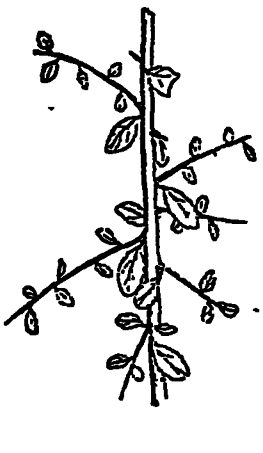

Fig. 65.

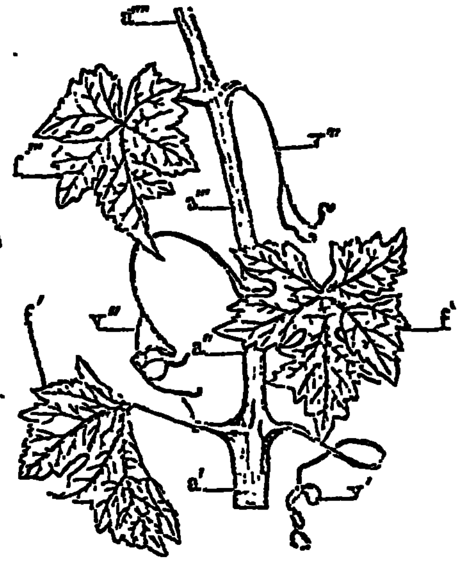

Fig. 66.

FIG. 65.—Branch of the Sloe (*Prunus spinosa*) producing spines or thorns which are abortive branches, as shown by their bearing leaves.
FIG. 66.—Portion of a branch of the Vine (*Vitis vinifera*), on which the terminal buds are converted into tendrils.

Fig. 66 represents the branch of a Vine, in which a' is the primary or first formed axis, ending in v', a tendril or altered terminal bud, and having a leaf f' on one side. Between this leaf and the tendril, which represents the axis, a leaf-bud was formed at an early date, producing the secondary axis, or branch a'', ending in a tendril v'', with a lateral leaf f'', from which a tertiary axis or branch a''' was developed, ending in a tendril v''', and so on. The tendrils of Ampelopsis Veitchii are terminated by disks which secrete a sticky matter, by means of which they adhere to walls, &c. The tendrils, like those of the Vine, are modifications of the axis. Tendrils twist in a spiral manner, and enable the plants to rise into the air by twining round other plants. The direction of the spiral frequently differs from that of the climbing stem which produces the tendril. In the Vine the lower part of the stem is strong, and needs no additional support; the tendrils therefore occur only in the upper part, where the branches are soft, and require aid to enable them to support the clusters of fruit. In the Bryony the tendril in the first part of its course twines from right to left, and in the last from left to right.

In some instances lateral buds are found without being in the axil of leaves. In this case they are *extra-axillary*. Such buds are produced after the stem and leaves have been formed, and in certain circumstances they are developed like normal buds. What have been called *embryo-buds* are woody nodules seen in the bark of the Beech, Elm, and other trees. They are partially developed adventitious or abnormal buds, in which the woody matter is pressed upon by the surrounding tissue, and thus acquires a very hard and firm texture. When a section is made, they present woody circles arranged around a central pith, and traversed by medullary rays. The nodules sometimes form *knots* on the surface of the stem, at other times they appear as large *excrescences*, and in some cases twigs and leaves are produced by them.

Buds sometimes become extra-axillary in consequence of the non-appearance or abortion of one or more leaves, or on account of the adhesion of the young branch to the parent stem. In place of one bud there are occasionally several accessory ones produced in the axil, giving origin to numerous branches. Such an occurrence is traced to the presence of latent or adventitious buds. By the union of several such buds, branches are produced, having

a thickened or flattened appearance, as is seen in the Fir, Ash, and other trees. These *fasciated* branches, in some cases, however, are owing to the abnormal development of a single bud. Occasionally adventitious buds are produced on the edges of leaves, as in Bryophyllum calycinum (fig. 67), Malaxis paludosa, and various species of Asplenium, and on the surface of leaves, as in Ornithogalum thyrsoideum. These are capable of forming independent plants. Similar buds are also made to appear on the leaves of Gesnera, Gloxinia, and Achimenes, by wounding various parts of them, and placing them in moist soil; this is the method often pursued by gardeners in their propagation. The Ipecacuan plant has been propagated by means of leaves inserted in the soil. In this case the lower end of the leaf becomes thickened like a corm, and from it roots are produced, and ultimately a bud and young plant. Leaves bearing buds on their margin are called *proliferous*.

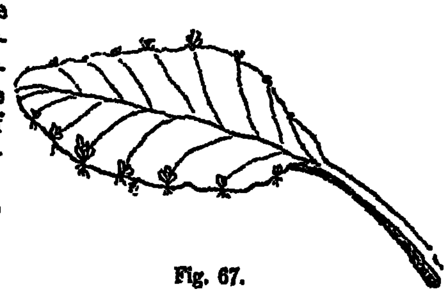

Fig. 67.

Leaf of *Bryophyllum calycinum*, producing buds along the margin, at the extremities of the primary veins.

The typical form of stems is rounded. They are sometimes compressed or flattened laterally, while at other times they are angular: being *triangular*, with three angles and three flat sides; *trigonous*, with three convex faces; *triquetrous*, with three concave sides; *quadrangular* or square; *quinquangular* or five-angled; *octangular* or eight-angled, &c. Various terms are applied to the forms of stems, as *cylindrical* or *terete*, *jointed* or *articulated*, &c. The following are some of the more important modifications of stems:—The *crown of the root* is a shortened stem, often partially under ground, which remains in some plants after the leaves, branches, and flower-stalks have withered. In this case the internodes are very short, and the nodes are crowded together, so that the plant appears to be stemless. It is seen in perennial plants, the leaves of which die down to the ground annually. A *rhizome* or *root-stock* (fig. 68) is a stem which runs along the surface of the ground, being partially covered by the soil, sending out roots from its lower side and leaf-buds from its upper. It occurs in Ferns, Iris, Hedychium, Acorus or Sweet Flag, Ginger, Water-lily, many species of Carex, Rushes, Anemone, Lathræa, &c. By many the term *rhizome* is applied to stems creeping horizontally, whether they are altogether or only partially subterranean. In rhizomes called definite, the terminal bud gives off flowers, and the lateral buds form the stem; while in indefinite rhizomes the terminal leaf-bud is formed annually. A rhizome such as occurs in Solomon's Seal (fig. 68) is not a single stem, *i.e.*, the product of a single bud, but is composed of portions of successive axes, the leaves of which have died off and remain as scars (fig. 68, *c*, *c*); it is thus an indefinite rhizome. Rhizomes are well seen in British Ferns. A rhizome sometimes assumes an erect form as in Scabiosa succisa, in which the so-called *præmorse* root is in reality a rhizome, with the lower end decaying. The erect rhizome of Cicuta virosa shows hollow internodes, separated by partitions.

Modification of stem

Fig. 68.

A *pseudo-bulb* (fig. 62) is an enlarged bulbous-like aerial stem, common in Orchidaceous plants. It is succulent, often contains numerous spiral cells and vessels, and is covered with a thick epidermis. A *soboles* is a creeping underground stem, sending roots from one part and leaf, buds from another, as in Couch-grass, Carex arenaria, and Scirpus lacustris. It is often called a creeping root, but is really a rhizome with narrow elongated internodes. A *tuber* is a thickened stem or branch produced by the approximation of the nodes and the swelling of the internodes, as in the Potato. The eyes of the Potato are leaf-buds. Tubers are sometimes aerial, occupying the place of branches. The ordinary herbaceous stem of the Potato, when cut into slips and planted, sends off branches from its base, which assume the form of tubers. Tubers frequently store up a quantity of starch as in Maranta arundinacea, whence arrowroot is derived. Another form of thickened underground stem is the *corm*, as seen in the Autumn Crocus (Colchicum, fig. 69), Gladiolus, &c. Structurally it is composed of a solid more or less rounded axis covered by a layer of thin membranous scales (fig. 70, *h*, *h*). A

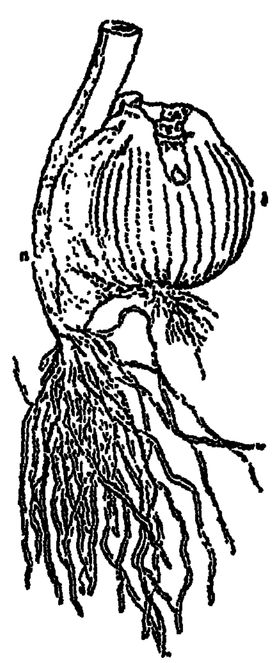

Fig. 69.

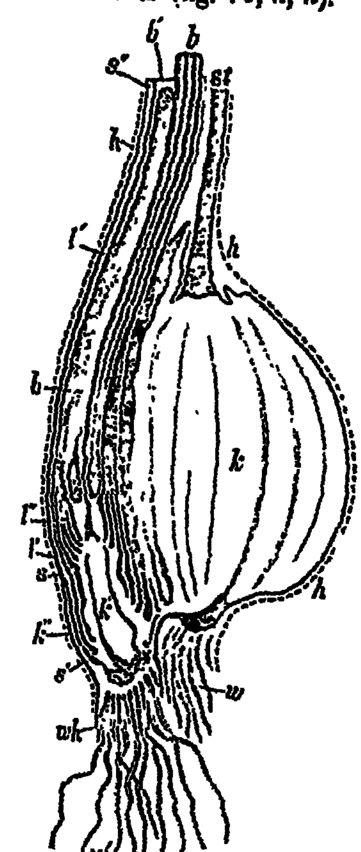

Fig. 70.

Fig. 70.—Corms of *Colchicum autumnale* in autumn when the plant is in flower. *k*, oldest corm; *h*, *h*, brown scales covering it; *w*, its roots; *st*, its withered flowering stem; *k'*, younger corm produced from *k*; *wk*, roots from *k'*, which grows at expense of *k*; *s*, *s'*, *s''*, sheathing leaves; *l'*, *l''*, foliage leaves; *b*, *b*, flowers; *k''*, young corm produced from *k'* in autumn, and which in succeeding autumn will produce flowers. (*Sachs.*)

corm is only of one year's duration, giving off buds annually in the form of young *corms*. In autumn the young corm gives origin to leaves, the lower of which (*s*, *s'*, *s''*) form sheaths round the corm and flower-stalk, the upper (*l'*, *l''*) remaining very small; and in the axil of the uppermost leaves the flowering-stem develops and bears the flowers (*b*, *b'*). Meanwhile in the axil of the middle leaves on the corm, a bud—the rudiment of a new corm—appears (*k''*). The flowering-stem dies down, and the corm from which it arose enlarges greatly during the winter at the expense of its parent corm (*k*), which thus becomes shrivelled. In spring the leaves produced *on it* (*l'*, *l''*), which were merely rudiments in autumn, appear above ground as conspicuous

large leaves. At the end of spring these leaves die down, the bases of the lower ones alone remaining, and constituting thin brown scales around the corm (as at *h*). Meanwhile, the young bud corm (*k''*) in the axil of the middle leaves grows rapidly at the expense of its parent corm (*k'*), but it does not attain a great size. In autumn it produces new leaves, which remain small, but from the axil of the two upper the flowering stem rises up and bears flowers; whilst in the axil of its middle leaves a new bud-corm appears, which will the following autumn produce young leaves, flowering stem, and a new bud-corm, and thus the cycle goes on. The buds or new corms formed from the old corms may be produced either laterally, as in Colchicum autumnale, or terminally, as in Crocus and Gladiolus. The *bulb* is another form of underground stem or bud. The axis in this case is much shortened, and the internodes are hardly developed. The bases of the leaves rising from the stem are quite close together, and become succulent and enclose the axis. In the Lily the thick and narrow scales are arranged separately in rows, and the bulb is called *scaly;* while in the Leek, Onion, Squill, and Tulip the scales are broad, and enclose each other in a concentric manner, the outer ones being thin and membranous, and the bulb is *tunicated.* In the axils of these fleshy scales new lateral shoots arise, forming new bulbs. The lateral buds or *cloves* sometimes remain attached to the axis, and produce flowering stems, so that apparently the same bulb continues to flower for many years, as in the Hyacinth and Tulip; at other times the young bulbs are detached, and form separate plants. In the axil of the leaves of Lilium bulbiferum, Dentaria bulbifera, and some other plants, small conical or rounded bodies are produced, called *bulbils* or *bulblets* (fig. 71, *b*). They resemble bulbs in their aspect, and consist of a small number of thickened scales enclosing a growing-point. These scales are frequently united closely together, so as to form a solid mass. Bulbils are therefore transformed leaf-buds, which are easily detached, and are capable of producing young plants when placed in favourable circumstances. The scales in bulbs vary in number. In Gagea there is only one scale; in the Tulip and Fritillaria imperialis they vary from two to five; while in Lilies and Hyacinths there are a great number of scales. In the Tulip a bud is formed in the axil of an outer scale, and this gives rise to a new flowering axis, and a new bulb, at the side of which the former bulb is attached in a withered state.

cture tem. The forms of the stem having been considered, we now proceed to examine its anatomical structure. This structure consists of the elementary tissues combined and arranged in various ways. The arrangement of the fibro-vascular bundles in the mature stem or root is not the same in all plants. But we find that in most plants which have two seed-lobes in the embryo, *i.e.*, Dicotyledons, a characteristic structure is apparent, quite distinct from what is found in the majority of plants in which only one seed-lobe is present in the embryo, *i.e.*, in Monocotyledons; and these, again, have a different structure from that found in Acotyledons, or plants with no seed-lobe in their embryo. The three forms of stem here referred to have been usually distinguished as follows:—(1.) *Exogenous* stem, in which the fibro-vascular bundles are produced indefinitely in an outward direction, and the stem increases in diameter by the annual formation of a new layer of woody matter on the outside of the preceding layers. This is the form found in most Dicotyledons, and they have hence been called *Exogens*, or Outward-growers. Ordinary trees, such as the Oak and Ash, furnish instances. (2.) *Endogenous* stem, in which the fibro-vascular bundles are definite, and are formed towards the centre, which becomes filled up with them in the progress of growth, so that the diameter of the stem increases in a great measure by the new matter pushing out that previously formed. This stem characterizes many Monocotyledons, which have thus been called *Endogens*, or Inward-growers. Palms supply examples. (3.) *Acrogenous* stem, in which the bundles of vessels are simultaneously developed, and the additions to the stem take place at the summit by the union of the bases of the leaves. Plants having this kind of stem are called *Acrogens*, or Summit-growers, and are Acotyledons. Tree-ferns furnish an example. Recent research, however, has shown that these terms cannot always be used as synonymous with Dicotyledon, Monocotyledon, and Acotyledon, as we find amongst Dicotyledons stems where the formation of new fibro-vascular bundles is distinctly endogenous, and again amongst Monocotyledons stems with a provision for exogenous growth, and also amongst Acotyledons examples are not wanting in which a continuous increase in diameter is provided for.

We shall consider the structure of the stem in Dicotyledons, Monocotyledons, and Acotyledons successively.

In the young stem of a Dicotyledon the fibro-vascular bundles first appear as a circle of wedge-shaped masses, by which the stem is divided into a central cellular portion, the *pith*, and a peripheral *cortex*,—the space between the bundles being occupied by cellular tissue constituting the *medullary rays*, and uniting the pith and cortex. Each fibro-vascular bundle increases by division of its own cambium cells. If eventually all the cambium cells become permanent tissue then the bundle becomes closed, and all further growth ceases. This is the complete structure of an annual herbaceous dicotyledonous stem, which thus consists of a central cellular pith, a circle of fibro-vascular bundles, a cellular cortex united with the pith by medullary rays, and outside all an epidermis (fig. 72). In trees and shrubs with permanent woody stems, the young shoots given out annually have a structure similar to that of annual herbaceous stems; but as the shoot grows, further changes occur by which the diameter is increased, and the stem becomes more dense. After the first year's growth, the cells of the medullary rays, stretching between the fibro-vascular bundles and continuous with their cambium cells, become converted into *secondary meristem*, and then an *interfascicular* cambium is formed, which eventually coalesces with the cambium cells of the fibro-vascular bundles, and thus a complete *cambium ring* is formed (fig. 73). From this cambium ring new xylem or wood is formed on the inside, whilst new cortex

Stem Dicoty dons.

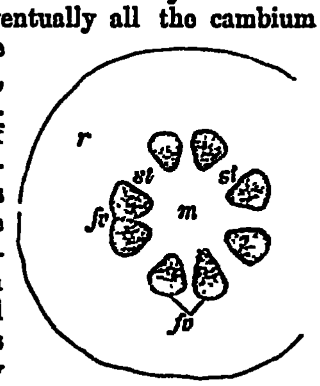

Fig. 72.
Young Dicotyledonous stem. *m*, pith; *fr*, wedge-shaped fibro-vascular bundles; *st*, medullary rays; *r*, cortex. Outside all is the epidermis. (*Sachs.*)

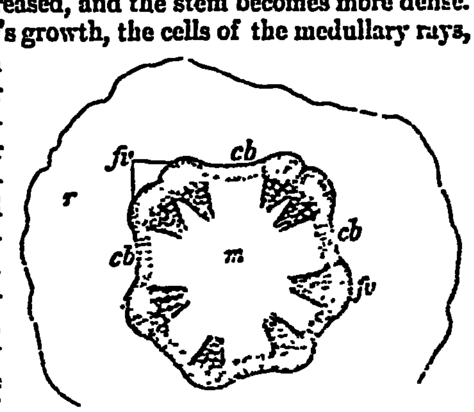

Fig. 73.
Young Dicotyledonous stem. *m*, pith; *fv*, fibro-vascular bundles; *cb*, [illegible] which a cambium ring is formed; *r*, cortex. (*Sachs.*)

is formed on the outside; and in this way the stem increases in thickness. This growth in thickness, however, ceases periodically, and is renewed with each new period of vegetation, and thus the wood is formed in concentric layers, sharply marked off from succeeding layers, each being an *annual ring* of wood, and the same is seen in the cortex (fig. 74). The rings of wood are thus formed successively outside those pre-existing, while in the cortex the new layers are produced inside those already formed.

The inner vessels of the primary fibro-vascular bundles immediately surround the pith and often project into it, and form what is termed the *medullary sheath*, which consists of spiral vessels, and through this sheath the primary medullary rays pass. These medullary rays extend from the pith to the cortex, but as new zones of wood and cortex are produced, new rays are formed in them, which increase by additions from the cambium layer. The secondary cortex, formed from the cambium ring, constitutes what is commonly known as the inner bark or *endophlœum*; the primary cortex, which forms the outer bark, consists of two layers of cells, which have been respectively termed the *mesophlœum* and the *epiphlœum*. Outside all is the epidermis. This, however, does not remain as thin-walled cells, but is usually converted into *periderm*, and this may in turn be completely supplanted by the bark. Thus, if a transverse and a longitudinal section of a Dicotyledonous stem be made, the following structures will be seen as represented in fig. 74. In the centre is the cellular pith *a*, *a*,

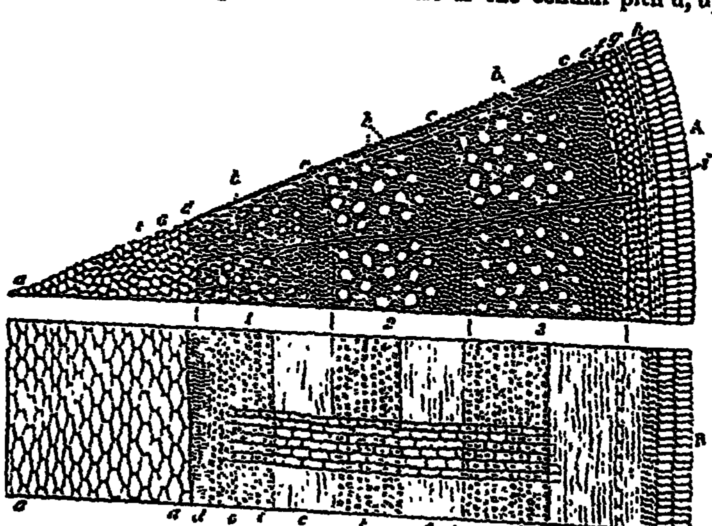

Fig. 74.

Diagram of the structure of an Exogenous or Dicotyledonous stem of three years' growth, A being a transverse section, and B a vertical section. The figures 1, 2, 3, mark the years of growth, and the letters refer to the same parts in both figures. *a*, *a*, medulla or pith, consisting of hexagonal parenchyma; *b*, *b*, *b*, pitted or dotted vessels, and *c*, *c*, *c*, wood-cells, of successive annual layers; *d*, spiral vessels of the medullary sheath; *e*, layer of cambium cells between wood and bark; *f*, inner bast layer of bark (Liber, Endophlœum); *g*, cellular envelope, forming middle layer of bark (Mesophlœum); *h*, outer corky layer of bark (Epiphlœum); *i*, *i*, medullary ray which, in the transverse section, is seen running continuously from the pith to the bark. (*After Carpenter.*)

immediately surrounding it comes the medullary sheath *d*, then the secondary layers of wood *b*, *c*, of successive years' growth, outside this the cambium ring *e*, separating the wood-layers from the cortical layers. Of these last, the inner, *f*, is the bast layer or endophlœum, *g* is the middle cellular layer or mesophlœum, and *d* is the outer epiphlœum. The latter two constitute the outer bark. Connecting the mesophlœum with the pith is seen a medullary ray *i*. Outside all are the epidermal tissues.

Let us now examine the different parts of an Exogenous stem proceeding from the centre to the circumference:—

Pith. The *Pith*, or the central part of a Dicotyledonous stem, is composed of cellular tissue. In the young stem it is succulent, the cells being full of fluid and frequently of a greenish hue; but in process of time it becomes pale-coloured, dry, and full of air. These changes take place first in the central cells. Sometimes the pith is broken up into cavities, which have a regular arrangement, as in the Walnut, Jessamine, and Cecropia peltata; it is then called *discoid* or *disciform*. At other times, by the rapid growth of the outer part of the stem, the pith is ruptured irregularly, and forms large cavities, as in the fistular stem of Umbelliferous plants. Plate VII. In some cases fibro-vascular bundles are found in the pith, as in Elder, Pitcher-plant, and Ferula, and occasionally its cells are marked by pores indicating a thickening of the cell-wall. The extent of pith varies in different plants and in different parts of the same plant. In Ebony it is small, while in the Elder it is large. In Æschynomene aspera (Shola plant, the Rice-paper plant of India), the interior of the stem is almost entirely composed of cellular tissue or pith; from this a kind of paper is made, and light hats. The same kind of tissue occurs in the Papyrus of the Nile. Large pith is also seen in Fatsia (Aralia) papyrifera (Tung-tsaou or Chinese rice-paper plant), and in Scævola Taccada of the Malay archipelago. When the woody circle of the first year is completed, the pith usually *remains stationary* as regards its size, retaining more or less its dimensions, even in old trunks, and never becoming obliterated.

The *Medullary Sheath* is the fibro-vascular layer immediately surrounding the pith. Medullary sheath. It is the inner layer of the fibro-vascular bundle of the first year (fig. 74, *d*), and consists chiefly of true spiral vessels, with annular and reticulated vessels, intermixed with long woody fibres, which continue to exercise their functions during the life of the plant, and which extend into the leaves. Between the vessels of the sheath the medullary rays from the pith pass.

The *Wood*.—The layers of wood (fig. 74, *b*, *c*) are formed The wood. outside the medullary sheath in concentric rings in the manner already described. On account of this mode of formation of wood-layers successively outside pre-existing layers the stem increases indefinitely. There are *no annular* or *spiral* vessels present; these have been replaced by pitted and punctated vessels along with wood-cells. The stems have been called *exogenous* and also *indefinite*, and Dicotyledonous plants have sometimes received the name of *Cyclogens*, in consequence of exhibiting concentric circles in their stems. On a transverse section each zone or circle is usually seen to be separated from that next to it by a well-marked line of demarcation. This line, as in the Oak and in the Ash, is indicated by holes which are the openings of large pitted vessels,—the remainder of the tissue in the circle being formed by pleurenchymatous tubes with thickened walls and of smaller calibre. In some trees, as the Lime, Hornbeam, and Maple, the line is by no means so well marked, as the openings are smaller and more generally diffused; but there is usually a deficiency of pitted vessels towards the outer part of the circle. In cone-bearing plants, as the Fir, in which the woody layers consist entirely of punctated tissue, without any large pitted vessels, the line of separation is marked by the tissue becoming dense and often coloured. In some kinds of wood, as Sumach, the zones are separated by a marked development of cellular tissue. The separation between the zones is owing to the interruption in the growth of the tree during autumn and winter, and hence it is well defined in trees of temperate and cold climates. But even in tropical trees, the lines, although often inconspicuous, are still visible,—the dry season, during which many of them lose their leaves, being their season of repose.

The woody layers vary in their texture at different periods. At first all the tissues are pervious and full of fluid; but by degrees they become thickened, and the channels of the vessels get filled up and obliterated. The first-formed layers are those which soonest become thus

altered. In old trees there is a marked division between the central *heart-wood* or *duramen*, and the external *sap-wood* or *alburnum*,—the former being hard and dense, and often coloured, with its tubes dry and thickened, while the latter is less dense, is of a pale colour, and has its tubes permeable by fluids. The difference of colour between these two kinds of woods is often very marked. In the Ebony tree the duramen or perfect-wood is black, and is the part used for furniture, while the alburnum is pale; in the Beech, the heart-wood is light-brown; in the Oak, deep-brown; in Judas tree, yellow; in Guaiacum, greenish. The alteration in colour is frequent in tropical trees. In trees of temperate climates, called *white-wood*, as the Willow and Poplar, no change in colour takes place; this is also the case in the Chestnut and Bombax. The relative proportion of alburnum and duramen varies in different trees. The heart-wood is more useful than the sap-wood, and is less liable to decay.

From the mode in which the woody layers are formed, it is obvious that each vascular zone is moulded upon that which precedes it; and as, in ordinary cases, each woody circle is completed in the course of one year, it follows that, by counting the concentric circles, the age of a tree may be ascertained. Thus fig. 75 represents an oak eight years old, having eight woody layers *b*. This computation can only be made in trees having marked separations between the circles. There are, however, many sources of mistake. In some instances, by interruption to growth, several circles may be formed in one year, and thus lead to an erroneous estimate. Care must be taken to have a complete section from the bark to the pith, for the circles sometimes vary in diameter at different parts of their course, and a great error might occur from taking only a few rings, or circles, and then estimating for the whole diameter of the tree. When by the action of severe frost, or other causes, injury has been done to the tender cells from which the young wood is developed, while, at the same time, the tree continues to live, so as to form perfect woody layers in subsequent years, the date of the injury may be ascertained by counting the number of layers which intervene between the imperfectly formed circle and the bark. Inscriptions made in the wood become covered, and may be detected in after years when a tree is cut down; so also wires or nails driven into the wood. As the same development of woody layers takes place in the branches as in the stem of an exogenous tree, the time when a branch was first given off may be computed by counting the circles on the stem and branch respectively. If there are fifty circles, for instance, in the trunk, thirty in one branch and ten in another, then the tree must have been twenty years old when it produced the first, and forty when it formed the other.

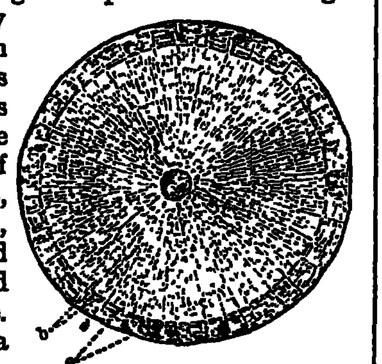

Fig. 75.

Horizontal section of the stem of an oak eight years old. *b*, wood, showing concentric circles or zones, separated by points which correspond to the opening of the large pitted vessels; *e*, bark, showing also eight concentric circles, thinner and less distinct. The wood and bark are traversed by medullary rays, some of which are the primary rays extending from the bark to the pith, while others (the secondary rays) reach only a certain way inwards.

In exogenous stems the pith is not always in the centre. The layers of wood on one side of a tree may be larger than those on the other, in consequence of their fuller exposure to light and air, or the nature of the nourishment conveyed, and thus the pith may become *excentric*. Zones vary in size in different kinds of trees, and at different periods of a plant's life. Soft wooded trees have usually broad zones, and old trees form smaller zones than young ones. There are certain periods of a plant's life when it seems to grow most vigorously, and to form the largest zones. This is said to occur in the Oak between twenty and thirty years of age.

Cambium.—External to the layers of wood, and between them and the bark, there is a layer of thin-walled cells in which the protoplasm and cell-sap remain, and consequently they are capable of division and growth. To this layer the name of *cambium* has been given. This cambium layer marks the separation between the wood and the bark, and may be regarded as constituting the active formative tissue of Dicotyledonous stems. It constitutes the *thickening zone*, by means of which the stem is enlarged,—the cambium cells situated most internally being subservient to the purposes of the wood formation, while the external ones give origin to the new bark. When these cells are carrying on the process of growth with activity, during the flow of the sap in spring, the bark can be easily separated from the wood. Cambium

The *Bark* or *Cortical System* lies external to the wood, and, like it, consists of several layers. In the early state it is entirely cellular, and is in every respect similar to the pith; but as the fibro-vascular bundles are developed, the bark and pith are separated, and the former gradually becomes altered by the formation of secondary deposits. We find in the cortex, as in the wood portion of the stem, fibro-vascular along with cellular tissue. But the position and relative proportion of these two systems is reversed. In the bark the cellular system is external, and is much developed, while the fibro-vascular is internal, and occupies comparatively a small space. The cellular portion of the bark consists of an external layer, or *epiphlœum*, and the cellular envelope, or *mesophlœum*, while the vascular system forms the internal portion called *liber*, or *endophlœum*. The bark.

The *endophlœum*, liber, or inner bark, is formed from the secondary cortex of the young stem. It consists mainly of thick or thin walled woody fibres, commonly known as bast-fibres, mixed with elongated cellular tissue and frequently with laticiferous vessels. It is separated from the wood by the cambium layer. The pleurenchymatous tubes are thickened so as to be flexible, but are not lignified, and are thus very tenacious. The endophlœum of the Lime-tree and of Antiaris saccidora (the Sack tree of Coorg) is used to form mats, cordage, and bags; and the toughness of the fibres of the inner bark of flax, hemp, and of many of the Nettle and Mallow tribes, render them fit for various manufacturing purposes. The endophlœum is sometimes, from its uses, called the *bast-layer*. Occasionally it is continuous and uninterrupted, as in the Vine and Horse-chestnut; at other times, as in the Oak, Ash, and Lime, the fibres are separated during the progress of growth, and form a sort of network, in the interstices of which the medullary rays are seen. The fibres of the Lace-bark tree (Lagetta lintearia) are similar. In fig. 76 is represented the bark of Daphne Laureola,—*f* indicating the woody fibres of liber, and *r* the medullary rays. The endophlœum increases by layers on its inside, which are thin, and may be separated like the leaves of a book. The outer layer of bast-fibres betwixt the endophlœum and the outer bark has been termed the *cortical sheath*, corresponding to the medullary sheath on the inside of the stem.

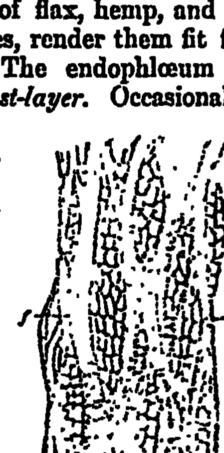

Fig. 76.

Network formed by liber of *Daphne Laureola*. *f. f.* [illegible]; *r. r.* medullary rays.

The outer bark is formed from the primary cortex; it is always cellular, and is divided into two layers, the epi-

phlœum with the mesophlœum underneath. The cellular envelope, or *mesophlœum*, lies immediately on the outside of the liber. It consists of polyhedral, often prismatical cells, elongated vertically to the surface, usually having chlorophyll, or green colouring matter, in their interior, but sometimes being colourless, and containing raphides. They are distinguished from those of the epiphlœum by their *form* and direction, by their thicker walls, their green colour, and the intercellular spaces which occur among them. This covering is usually less developed than the outer suberous layer, but sometimes, as in the Larch and common Fir, it becomes very thick, and separates like the epiphlœum. In the cellular envelope laticiferous vessels occur. The *epiphlœum* is the outer covering of the bark, consisting of cells which usually assume a cubical or flattened tabular form. The cells have no chlorophyll in their interior, are placed close together, and are elongated in a horizontal direction; and thus they are distinguished from the cells of mesophlœum. In the progress of growth they become often of a brown colour. This covering may be composed of a single layer of tabular cells; but in some trees it consists of numerous layers, forming the substance called *cork*, which is well seen in Quercus Suber, the Cork-oak; hence the name *suberous*, or *corky layer*, which is given to it. The form of its cells varies in some instances, being cubical at one part, and more compressed or tabular at another, thus giving rise to the appearance of separate layers. On the exterior of the epiphlœum is situated the epidermis, which has already been described. It is formed of a layer of cells, which in woody stems serve only a temporary purpose, becoming ultimately transformed in various ways.

The bark, in its increase, follows an order exactly the reverse of that which occurs in the woody layers. The layers of liber owe their increase to the cambium cells, which, by their constant reproduction, mark the separation between the xylem and phloëm portions of the stem. These layers are often so compressed and united together as to be counted with difficulty, while at other times they are separated by rings of cellular tissue, and thus remain conspicuous. As the additions are made to the woody layers on the outside, and to the bark on the inside, there is a constant distension going on, by which the bark becomes compressed, its layers of liber are condensed, the fibres are often separated (fig. 76) so as to form meshes, its epidermis is thrown off, and the epiphlœum is either detached along with it, or, when thick, is ruptured in various ways, so as to give rise to the rugged appearance presented by such trees as Elm and Cork-oak. In some instances the bark is very distensible, and its outer cellular covering is not much developed, so that the surface remains smooth, as in the Beech. The outer suberous layer sometimes separates with the epidermis, in thin plates or scales; in the Birch these have a white and silvery aspect. There is thus a continual destruction and separation of different portions of the bark. The cellular envelope and liber may remain while the epiphlœum separates, or they also may be gradually pushed off—the parts which were at first internal becoming external. In the case of some Australian trees both the cellular and fibrous portions are detached in the form of thin flakes, and occasionally each annual layer of liber pushes off that which preceded it. The epidermis separates early, and no renewal of it takes place. It *is*, however, replaced by the cork layer, which then covers the outer part of the stem. To this covering the name *periderm* is given.

From the mode in which the outer layers of bark separate, it follows that inscriptions made on them, and not extending to the wood, *gradually fall* off and disappear. A nail driven into these layers ultimately falls out. In consequence of the continued distension of an exogenous stem, it is found that woody twining plants cause injury, by interrupting the passage of the fluids. Thus a spiral groove may be formed on the surface of the stem by the compression exercised by a twining plant, such as Bush-rope (Bauhinia, fig. 77) or Honeysuckle. From what has been stated relative to the changes which take place in the bark, it will be understood that it is often difficult to count its annual layers, so as to estimate the age of the tree by means of them. This may, however, be done in some cases, as shown at fig. 75, where there are eight layers of bark *e*, and eight woody layers *b*.

Medullary rays.

Fig. 77.

Stem of an Exogenous tree, surrounded by a woody climber called Bush-rope.

Medullary Rays or Plates.—While the bark and pith become gradually separated by the intervention of vascular bundles, the connection between them is kept up by means of processes called *medullary rays* (figs. 78 and 79). These form the *silver grain* in wood, so conspicuous in the maple; they communicate with the pith and the cellular envelope of the bark, and they consist of cellular tissue, which becomes compressed and flattened so as to assume a muriform appearance. At first they occupy a large space (fig. 72, *st*); but as the vascular bundles increase they become more and more narrow, forming thin laminæ or plates, which separate the woody bundles. On making a transverse or horizontal section of a woody stem, the medullary rays present the aspect of narrow lines running from the centre to the circumference (fig. 74); and on making a vertical section of a similar stem through one of the rays, the appearance represented in fig. 78 will be observed, where a medullary ray *mr*, composed of flattened muriform cells, passes from the pith *p* to the cellular

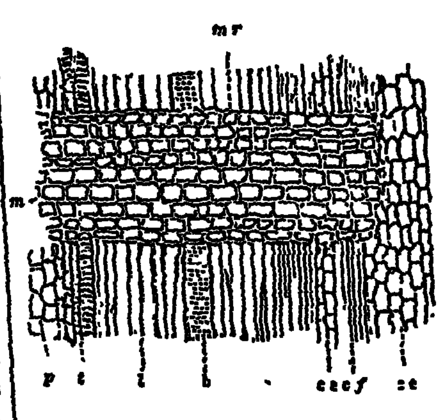

Fig. 78.

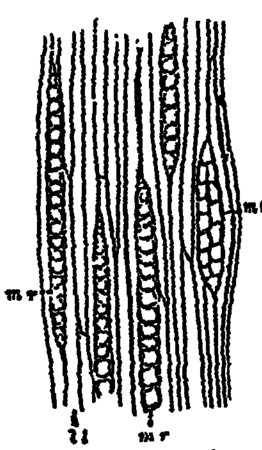

Fig. 79.

FIG. 78.—Vertical section of a young Dicotyledonous stem, parallel to the medullary rays.
FIG. 79.—Vertical section of the same, tangential to the medullary rays.

envelope *ce*, crossing the tracheæ of the medullary sheath *t*, the ligneous tissue *l*, the pitted vessels of the wood *b*, and the fibres of the liber *cf*. The laminæ do not by any means preserve an uninterrupted course from the apex to the base of the tree. They are broken up by the intervention of woody fibres, as seen in a vertical section of a woody stem (fig. 79), tangentially to the medullary rays *mr*, *mr*, *mr*, which are separated by interlacing fibres *ll*. The primary medullary rays extend completely from the pith to the bark; but in the secondary wood and secondary cortex new rays are formed which, therefore, extend only through a portion of the stem. These are secondary medullary rays. All may increase by division of the merismatic cells of the cambium. Medullary rays are conspicuous in the Cork-Oak, Hazel, Beech, Ivy, Clematis, Vine. They are not so well marked in the Lime, Chestnut, Birch, Yew,

The medullary rays are in some cases, as in Clematis and Aristolochia, large and broad, while the woody wedges are comparatively small.

The stems of Dicotyledonous plants occasionally present anomalous appearances in the structure and arrangement of their wood, bark, and medullary rays. In place of concentric circles there are sometimes only a few rows of wedge-shaped vascular bundles produced during the life of the plant, additions being made by the annual interposition of bundles of a similar kind, resembling in this respect the formation of woody bundles in the early growth of herbaceous plants. In Piperaceæ, Aristolochiaceæ, and Menispermaceæ, these anomalous stems occur. In Gnetum (fig. 80), the vascular bundles, *b, b, b, b, b*, form zones, which

FIG. 80.—Horizontal section of stem of Gnetum. *m*, pith; *em*, medullary sheath; *b, b, b, b, b*, woody bundles forming seven concentric zones, each of which is the produce of several years; *l, l, l, l, l, l*, fibres of liber, forming interposed circles equal in number to the woody zones.

FIG. 81.—Peculiar stem of a Malpighiaceous plant of South America. The plant is Dicotyledonous.

are each the produce of several years' growth, and are separated by layers, *l, l, l, l, l, l*, which may be considered as representing different bast-layers. In some of the Menispermaceæ the separating layers are of a cellular and not of a fibrous nature. Many of the Malpighiaceæ, Sapindaceæ, and Bignoniaceæ of Brazil exhibit stems in which the woody layers are arranged in a very irregular manner. In some of them (fig. 81) there is a central woody mass with from three to ten small secondary ones round it. Each of the masses contains true pith, derived either from the cortical cellular tissue, or from the original medullary centre. Around these separate collections of pith there is a medullary sheath and spiral vessels. No annual rings have been detected in the secondary masses, but medullary rays exist usually in their outer portion. In some anomalous Sapindaceæ, the central and lateral woody masses are enclosed in a common bark, with a continuous layer of liber. Some have supposed that the lateral masses are undeveloped branches united together under the bark.

In some Bignoniaceæ (fig. 82) the layers of wood are divided

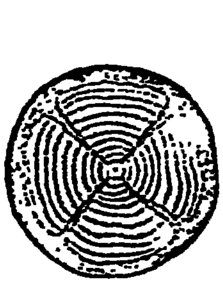

Fig. 82.

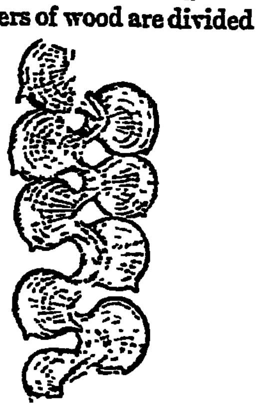

Fig. 83.

FIG. 82.—Horizontal section of the stem of *Bignonia capreolata*, showing the crucial division of the woody layers.

FIG. 83.—Fragment of a stem of a climbing species of Banisteria (*B. scandens*), showing the effects of compression.

in a crucial manner into four wedge-shaped portions by the intervention of plates differing in texture from the ordinary wood of the plant, and probably formed by the introversion, or growing inwards, of the liber. In Aspidosperma excelsum (Paddle-wood) of Guiana, and in Heteropterys anomala, the stem assumes a peculiar lobed and sinuous aspect; and in some woody climbing plants pressure causes the stems to become flattened on the side next the tree on which they are supported, while from being twisted alternately in different directions, they present a remarkable zigzag form, having the woody layers developed only on one side (fig. 83). In Firs the wood is occasionally produced in an oblique in place of a perpendicular manner, thus injuring the timber and causing it to split in an unusual way. The young plants produced from the seed of such twisted-wooded firs are said to inherit the peculiarity of their parents. Occasionally the Dicotyledonous stem becomes swollen at certain places, especially near the root, and thus exhibits a tuberous appearance. This peculiarity is said to be liable to occur in Coniferous plants grown from cuttings. In some of the lower class of plants a cellular stalk is produced, which on a transverse section presents an appearance like that of a Dicotyledonous stem. Thus Lessonia fuscescens, a species of sea-weed, has stems which are often 5 to 10 feet long, and as thick as the human thigh, and which show concentric elliptic cellular rings. Such is also the case with Usnea melaxantha, a tree-like lichen. In these plants, however, the structure is entirely cellular, and quite distinct from that of Dicotyledonous plants.

Stem in Monocotyledons.

In the young stem of a Monocotyledonous plant the fibro-vascular bundles appear scattered in an irregular manner through the fundamental parenchyma, becoming more numerous towards the periphery. There is thus no primary separation in the stem into pith, cortex, and medullary rays, although the central cellular mass may be considered as representing the pith. Thus, if a section be made across a young Monocotyledonous stem, an appearance is observed such as is represented in fig. 84, where the vessels are seen

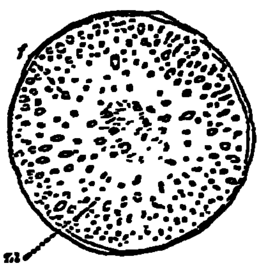

Fig. 84.

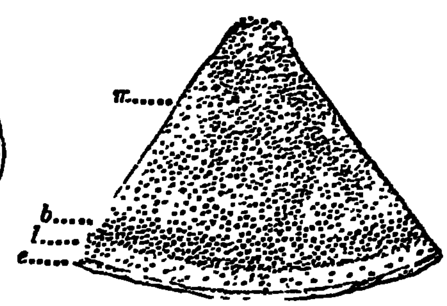

Fig. 85.

FIG. 84.—Transverse section of the stem of a Palm, which is Monocotyledonous. *m*, the central loose cellular portion; *f*, the outer fibrous portion, showing numerous vascular bundles. The whole being covered by a false bark or rind.

FIG. 85.—Transverse section of the stem of a Palm, more advanced.

as points scattered through a cellular matrix, the circumference not having any marked cortex, and the whole covered by an epidermis. A similar section of a further advanced stem, as of a Palm (fig. 85), shows numerous bundles of vessels dispersed irregularly in cellular tissue; those near the centre, *m*, being scattered at a distance from each other, while those towards the outside are densely aggregated, forming a darkish zone *b*, and are succeeded at the circumference by a paler circle of less compact vessels *l*, with some compressed cells, covered by an epidermis *e*. The central cellular mass has no medullary sheath. In some cases its cells are ruptured, and disappear during the progress of growth, leaving a hollow cavity; but in general it remains permanent, and is gradually encroached upon by the development of the vascular system. The peripheral portion differs from *true* bark in not being separable from the rest of the tissue. It has received the name of *false* bark, and consists of the epidermal cells *e*, and what has been called the cortical integument, *l*. This

portion of the stem is often very inconspicuous, but sometimes it is much developed, as in Testudinaria Elephantipes, in which it is rugged, and is formed of a substance resembling cork in many respects. The fibro-vascular bundles of the stem very soon become closed, and thus all growth in them ceases, the cambium cells being converted completely into permanent tissue. Fig. 57 represents a transverse section of a closed fibro-vascular bundle from the stem of the maize (Zea Mays). In it the several elements seen in the section of the fibro-vascular bundle from a Dicotyledonous stem may be recognized, but there is no cambium, the cells marked *v*, *v* representing those cambiform cells which have last become permanent tissue. This absence of cambium necessarily curtails the growth of the bundle, and hence the limited diameter characteristic of the stems of Monocotyledons. In fig. 86 a diagram

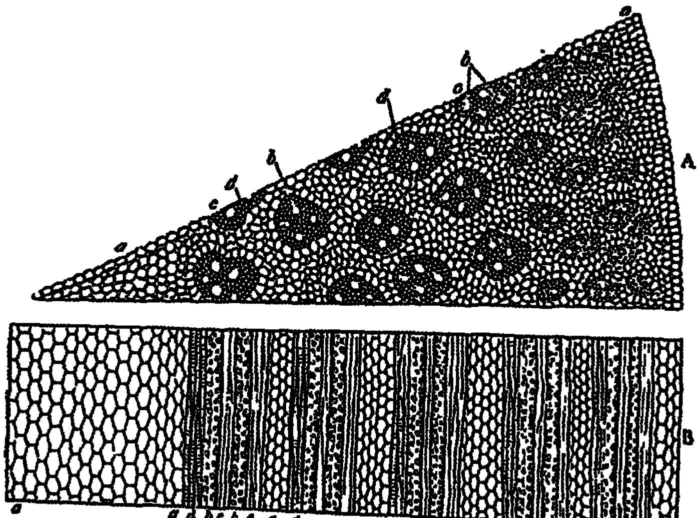

Fig. 86.

Diagram of a Monocotyledonous stem. A, transverse section; B, longitudinal section; *a*, *a*, cellular tissue (Parenchyma); *b*, *b*, dotted vessels (Bothrenchyma); *c*, *c*, woody fibres (Pleurenchyma); *d*, *d*, spiral vessels (Trachenchyma). (*After Carpenter.*)

represents a transverse and longitudinal section of a Monocotyledonous stem.

All the fibro-vascular bundles of the stem are *common* bundles, that is, they pass out into the leaf, and in these stems each bundle has a definite arrangement. At the point where the bundle curves out into the leaf it has its greatest thickness, gradually becoming attenuated as it passes upwards into the leaf and downwards into the stem. In some instances, however, the bundles as they descend increase at different parts of their course, probably by *interstitial* growth, and give rise to irregular swellings of the stem, as in Ceroxylon Andicola. The distension takes place occasionally at the base of the stem, as in Euterpe montana. This downward prolonged portion does not, however, run a straight course, but first passing inwards towards the centre of the stem, it then gradually arches outwards towards the periphery. This passing inwards at first of the fibro-vascular bundle gave origin to the idea that the first formed fibres were gradually pushed towards the circumference by those which succeeded them, and that the wood portion of these stems was increased by additions to the centre; hence the term endogenous applied to them, meaning internal growth. But, as has been shown, the fibro-vascular bundles really become external at the base, although internal above. On making a vertical section of the endogenous stem, as of a Palm (fig. 87), there is observed an interlacing of fibres, the fibro-vascular bundles are first directed towards the centre, and then curve outwards towards the circumference, so that those last formed ultimately become external. The term endogenous will, therefore, only apply strictly to the fibres at the early part of their course. The true distinction between exogenous and endogenous stems is, that in the former the fibro-vascular bundles remain open, a cambium ring being eventually formed from which the stem increases indefinitely in diameter. In the latter the fibro-vascular bundles soon become closed, and being scattered irregularly through the cellular tissue, and not in a circle, no cambium ring can be formed, and thus growth in a transverse direction is soon arrested, and the stem is of a comparatively uniform diameter throughout. The investing bark of the former permits an unlimited extension of woody growth beneath it; the fibrous cortical layer of the latter, by maintaining an intimate union with the subjacent tissue, prevents unlimited increase in diameter. Hence we find that the stem does not attain the enormous diameter exhibited by some Dicotyledonous trees, such as Sequoia (*Wellingtonia*) gigantea and the Baobab,—the former of which has been measured 116 feet in circumference. In consequence of this mode of formation, the outer part of a Palm-stem is the hardest and densest, and after acquiring a certain degree of firmness it resists all further distension, and frequently becomes so hard as to withstand the blow of a hatchet, and therefore a woody twining plant does less injury to it than to trees of exogenous growth (fig. 88). The growth

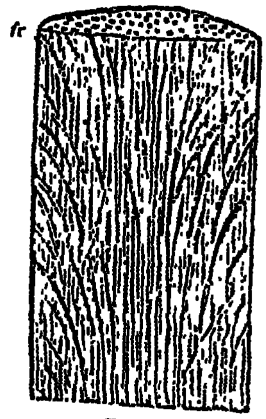

Fig. 87.

Fig. 88.

FIG. 87.—Vertical section of a Palm-stem, showing the vascular bundles, *fr*, curving downwards and interlacing.
FIG. 88.—Monocotyledonous stem, surrounded by a twining woody plant, and remaining uninjured.

of endogenous stems may be said to resemble an upward growth of an exogen by the terminal bud only, for there is no cambium layer, and no peripherical increase. The terminal central bud is called a *phyllophor* or *phyllogen*. As growth only proceeds in this manner, no annual rings of wood are formed. From the absence of concentric circles the age of a Palm cannot be estimated in the same way as that of an exogenous tree. The elongation, however, of each species of Palm is pretty regular, and by this some idea may be formed of its age. There are many herbaceous plants in Britain, as Lilies, Grasses, &c., having Monocotyledonous stems, but there are no British Monocotyledonous plants with permanent aerial woody stems. All the British trees are Dicotyledonous. Illustrations of Monocotyledonous stems must be taken from trees of other countries, and of these Palms furnish the best examples.

Although this limited growth in a transverse direction is characteristic of most Monocotyledons, we find instances where a true thickening ring is formed and an indefinite increase in diameter takes place, as in Dracæna, Yucca, &c. This thickening ring, however, originates in a manner different from that in Dicotyledonous plants. A layer of the fundamental cellular tissue parallel to the surface of the stem becomes merismatic, and produces new closed fibro-vascular bundles and new cellular tissue

between them. The new woody tissue so formed thus corresponds to the secondary wood in Dicotyledonous stems, and the new fibro-vascular bundles are all cauline, that is, do not pass out into the leaves. By this means an enormous increase in diameter of the stem may take place. And not unfrequently the primary central portion of the stem gives way, and thus a hollow cylinder formed by this secondary wood remains. This was well seen in the famous Dracæna Draco, or Dragon tree of Orotava, in the Canary Islands, which had a hollow stem capable of holding several men.

The composition of the vascular bundles in different parts of their course varies. Thus, at the upper part, tracing them from the leaves towards the centre, they contain spiral vessels, pitted vessels with some cellular tissue, a few laticiferous vessels, and woody fibres resembling those of liber. As we descend to the older portions of the bundle, where the tissues have become permanent throughout, the spiral vessels disappear, then the pitted vessels, and at the periphery nothing but pleurenchymatous tissue remains, forming a complicated anastomosis or network. Not unfrequently at the nodes of the stem a network of horizontal vessels occurs. They are well seen in many Grasses, where the central portion of the stem has given way, and there they serve to strengthen the stem. The branching of Monocotyledonous stems is originally the same as in Dicotyledons, namely, a monopodial form; frequently however, the axillary buds do not unfold, and the form becomes much varied. In Palms this is well seen, and usually no lateral shoots are formed. In some Palms, however, as the Doum Palm of Egypt (*Hyphæne thebaica*), the lateral shoots are developed in such a way that the stem appears to fork. Other examples of the development of branches are seen in the case of the Screw-pine (*Pandanus*), in Grasses, as the Bamboo, in Asparagus, Cordyline, Dracæna, &c. In some instances the axillary shoots detach themselves from the parent stem and form an independent plant, as in Lilium bulbiferum (fig. 71). The bases of the leaves produced from the stem remain attached to the stem in many Palms, being surrounded by a fibrous substance, the *mattulla or reticulum.*

When the internodes of the caudex of a Palm are not much elongated, the scars of the leaves are seen forming spirals on the stem, as in the Coco-nut and Date. In Xanthorrhœa Hastile the same arrangement is observed. In this plant also a curious internal structure of the stem occurs. On making a vertical section the structure appears to be that of a Dicotyledon. The woody part is formed of vertical loose fibres as in Palms, and there are other fibres, radiating from the centre, and cutting the preceding at right angles. These horizontal fibres resemble the medullary rays, but differ in their structure. They probably serve for the origin of leaves, which are numerous, and are disposed throughout the whole length of the stem. In Palms, such as species of Chamædorea, the internodes are much lengthened, and rings are seen on the stem at distant intervals, showing thickened node-like joints. Some Palm stems, as those of Calamus Rudentum, the common Cane, are very thin and slender. In many Monocotyledonous plants the stem remains below ground, developing shoots which are simple, as in Banana and Plantain, or branched, as in Asparagus. In the former the stem above ground is an herbaceous shoot, composed of the sheaths of the leaves. It dies after fruiting, and is succeeded by other shoots from the subterranean stem. The shoots or buds from such stems occasionally remain in part below ground in the form of bulbs, as in Lilies, Tulips, and Hyacinths; or as corms, as in Colchicum, Crocus, Gladiolus, and Arum. In some instances the aerial stem has the usual Monocotyledonous structure, while in the underground stem the fibro-vascular bundles are arranged in a circle, enclosing a central cellular mass or pith, and thus resembling in structure a Dicotyledonous stem. This structure has been remarked in the Smilax or Sarsaparilla family. Lindley calls these plants *Dictyogens*, from their netted leaves, by which they differ from most Monocotyledons.

ate XVI. . 2.

Stem in Acotyledons.

Amongst Acotyledonous plants there are some which possess stems consisting entirely of cellular tissue, whilst in others the stems have a well-developed vascular system. Of the former we have examples in Mosses, Hepaticæ, and Characeæ; the latter we find represented in Ferns, Equisetaceæ, and Lycopodiaceæ. The term *Acrogenous* has been used as descriptive of the stems of Acotyledonous plants, as they were supposed to be formed by additions to the summit, and by the elongation of vessels already formed. They are also sometimes called *Acrobrya*. But as in the case of the terms exogenous and endogenous applied to the stems of Dicotyledons and Monocotyledons respectively, recent research has shown that the term acrogenous cannot have the significance formerly attached to it; for in some Acotyledonous plants a true cambium ring is formed by which layers of tissue are successively added, and the stem increases in diameter, and also in many instances the fibro-vascular bundles develop from above downwards. The characters of the stem, however, enable us easily to distinguish it from that in Dicotyledons or Monocotyledons. With merely a slight exception there is no provision for lateral growth of the stem, and all increase in size takes place by an elongation of the terminal growing-point. No cambium ring is as a rule formed; where it does exist, it is not produced in the same way as in Dicotyledons, but rather resembles the formation of the cambium ring in Dracæna amongst Monocotyledons. When a permanent woody stem occurs amongst Acotyledonous plants it resembles in general aspect the stem of a Monocotyledonous plant, having nearly a uniform height, and being usually unbranched and producing a tuft of leaves (fronds) at the summit. Tree-ferns furnish the best example of this kind of stem. In them it is denominated a *stipe*, and it often attains the height of 120 feet. The stem in Acotyledonous plants is distinguished from that in Dicotyledons by the absence of annual rings of wood, of (with only slight exception) a cambium ring, of a separable bark, and by the fact that the fibro-vascular bundles are all closed; in this latter character they agree with Monocotyledons, but are distinguished from them by the arrangement of the vascular bundles.

In Acotyledonous stems growth takes place by division of a single apical cell, situated at the extreme end of the punctum vegetationis. By divisions of this cell two portions of tissue are marked out in the stem,—an inner portion, from which arise the fibro-vascular tissues when they exist, and an outer or cortical portion. The primary fibro-vascular bundles originate from the cellular tissue of the stem in a manner analogous to what occurs in Dicotyledons and Monocotyledons,—a procambial bundle being first formed, which differentiates subsequently into xylem and phloëm layers, but the bundles always become closed. The character of the stem varies very much in the several families of Acotyledonous plants.

Characeæ.

In Characeæ the stem consists of a series of joints (internodes), each composed of a single much elongated cell. Interposed between successive internodes are the nodes, each composed of a whorl of small cells, from which the leaves are developed, one leaf from every cell of the node. In the genus Chara a cortex is found completely investing the internodal cell. It is formed by the development, from every cell, of the nodes of an ascending and descending lobe. The ascending lobes of one node and the descending lobes of the next higher node meet in the middle of the intervening internode, and there interlock in

a prosenchymatous manner. Subsequently by cell-division a complicated structure is developed in this investing mass. No fibro-vascular bundles are found in Characeæ.

Mosses. In Mosses and many Hepaticæ we find no fibro-vascular system, but a slender leafy cellular stem. In it there is sometimes a differentiation into an inner and a peripheral mass of tissue. In the former the cells have usually thin walls, and are not coloured, though in some cases a thickening of the walls of the central cells is observed, and a sort of rudimentary bundle is formed. The circumferential cells have usually thickened walls, and are not unfrequently coloured.

Ferns. In Ferns we have a familiar example of an Acotyledonous stem. Ordinary ferns of Britain seldom attain any height, but usually creep along the ground, forming rhizomes. But in the Tree-ferns of warm climates the caudex frequently attains a great height. A transverse section of the stem of a fern (fig. 89) exhibits an irregular circle of fibro-vascular bundles, composed of masses *f*, *v*, of various forms and sizes, situated near the circumference,—the centre *m* being formed of cellular tissue, frequently with solitary fibro-vascular bundles scattered through it, and often becoming hollow. On the outside of the vascular circle cells exist, *p*, covered by an epidermal layer or cellular integument *e*, often of hard and dense consistence, and marked with the scars of the fronds.

The vascular system is of greater density than the rest of the tissue, and is distinguished by the dark colour of the outer portion (fig. 89, *f*), which surrounds the paler

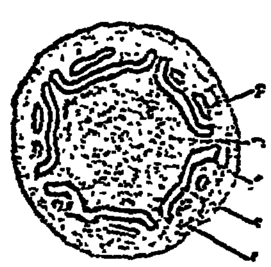

Fig. 90.

constitutes the inner, lighter-coloured portion of the bundles. The phloëm portion, which completely surrounds the bundle, has also starch-cells, and, in addition, sieve-tubes and elongated bast-like thick-walled fibres are found at the periphery of the bundle. The whole bundle is usually enclosed by a distinct sheath of elongated cells; these cells are frequently much thickened and of a dark brown colour, hence the appearance presented on transverse section of a dark layer enclosing a lighter-coloured part. The central cellular portion of the stem frequently becomes ruptured and absorbed in old stems, which are thus hollow. The bases of the leaves remain long attached, but ultimately fall off, leaving marked scars (fig. 91, *c*), which are at first

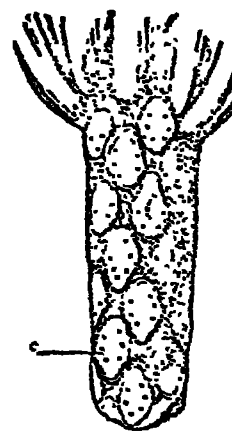

Fig. 91.

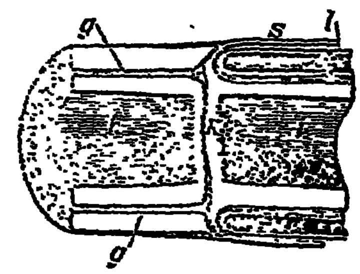

Fig. 92.

FIG. 91.—Rhizome of Male Fern, *Lastrea (Aspidium) Filix-mas*, showing the scars (cicatrices) of the leaves (fronds), with the markings of the vascular bundles, *c*.
FIG. 92.—Longitudinal section of rhizome of Equisetum, showing septum, *k*, between cavities *h*, *h*; *g*, *g*, fibro-vascular bundles; *l*, vallecular canal; *s*, leaf-sheath. (*Sachs*.)

close together, but often separate afterwards by interstitial growth. On these scars or *cicatrices* the markings of the vessels are easily seen, arranged in the same manner as those of the stem. From all points of the woody cylinder stem-roots may be given off, and frequently they are formed so abundantly as completely to invest the stem and conceal it.

In Equisetaceæ or Horsetails we have another example of an Acotyledonous stem. The true stem in those plants is a rhizome underground, from which aerial shoots are sent up annually. Every aerial stem consists of a series of joints (internodes), which are usually hollow and closed at their base by a thin septum (fig. 92). Each internode passes up into a leaf-sheath embracing the next internode, and this sheath is usually split into teeth at its upper margin. In transverse section a circle of fibro-vascular bundles is seen (fig. 93) marking off an inner medullary from an outer cortical portion, and separated one from the other by a mass of parenchyma. These bundles are all common bundles. From each tooth of the leaf-sheath the bundle may be traced, passing vertically down into the internodes In Equisetaceæ.

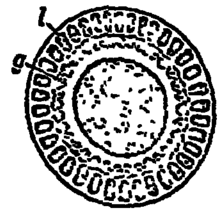

Fig. 93.

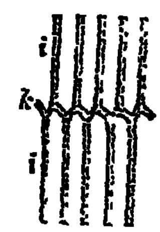

Fig. 94.

FIG. 93.—Transverse section of a rhizome of Equisetum. *g*, fibro-vascular bundles; *l*, vallecular canal; *h*, central cavity. (*Sachs*.)
FIG. 94.—To show union of the fibro-vascular bundle of an upper with a lower internode; *i*, *i*, internode; *k*, node. (*Sachs*.)

as far as the node beneath, and at the lower end dividing into two, uniting by each branch with a bundle of the next lowest internode (fig. 94). In transverse section the bundle

resembles much that of a Monocotyledon. One peculiarity, however, must be noticed. The spiral, annular, and reticulated vessels at the inner side of the bundle soon disappear, and an air-canal is formed in the bundle. This canal must be distinguished from the *vallecular* canals found in the cortex, with which they alternate. Round the bundles a single layer of usually thickened and coloured cells forms a sheath, and this may either run continuously round the stem, and thus shut off completely the medullary from the cortical portion of the stem, or may invest separately each bundle, in which case the medullary and cortical portions of the stem are continuous. In some cases a layer of thickened cells is found within the vascular bundles. The cortical portion is divisible into two layers, an inner layer of parenchymatous cells with air canals, the *vallecular* canals, and an outer layer of thickened cells immediately underlying the epidermis. The structure of the rhizome resembles that of the aerial stem, differing only in the fact that the thickened cells of the outer cortical layer are dark coloured, and that the central canal of the internodes is often absent. In Calamites, a fossil plant which flourished abundantly during the Carboniferous Period, we have a plant which in all particulars is closely allied to Equisetum of the present day. But whilst the young stem of Calamites presented a zone of vascular bundles separating it into a medullary and cortical portion (just as in an Equisetum), new vessels were added to the exterior of the pre-existing bundles as the plant grew, so that a series of woody wedges were formed, increasing in growth to an enormous extent.

ypo- eæ. In Lycopodiaceæ, or Club Mosses, the stem presents differences from that in Ferns and Equisetaceæ. In most members of the family there is an axial cylinder formed of either one or more fibro-vascular bundles. In some cases (Selaginella) the fibro-vascular bundles remain separate and do not form a cylinder. They are surrounded by a mass of prosenchymatous cellular tissue, the cells of which may be thin-walled, leaving no intercellular spaces, or the cell-walls may be much thickened. Immediately surrounding the central axial bundle in Selaginella are large air lacunæ, which are wanting in Lycopodium. The fibro-vascular bundles consist of tissues very similar to what occurs in Ferns, and the bundles are all cauline. In the leaves, bundles arise which pass into the stem and coalesce with the cauline bundles. In Isoetes we find a most anomalous structure. Here there are no internodes in the stem; consequently, it is much shortened. The central axial fibro-vascular bundle is very poorly developed, and round it a meristem is formed, which, by adding new parenchyma outside, increases the diameter of the stem. Thus we have here a thickening ring, but it differs from that structure in Dicotyledons, inasmuch as it is not formed by a union of cambium cells of the fibro-vascular bundles. It resembles more the thickening ring formed in Dracæna, Yucca, and other Monocotyledons.

zo- peæ. In Rhizocarpeæ the structure of the stem is very simple, consisting of an axial fibro-vascular bundle surrounded by parenchyma full of air-cavities.

In plants with Acotyledonous stems the mode of branching is various. In Lycopodiaceæ we have an example of a dichotomous branching, and the same is also seen in Ferns. In the Equisetaceæ a mode of branching occurs seen nowhere else in the Vegetable Kingdom. The branches arise from deeply-seated lateral buds, which, upon developing, break through the superincumbent tissue; these have been termed *endogenous* buds. In Characeæ the branching is of the normal monopodial type.

allogens. Amongst Thallogens, as a rule, there is no evident distinction between stem and leaf. The vegetative organs consist of a number of cells separate or combined into a more or less flattened expansion termed the thallus. In this group are included all the Algæ, Fungi, and Lichens, and many Hepaticæ. The vegetative structures vary much in each of these groups. In many Hepaticæ, as Marchantia, the vegetative structure is of a thalloid nature, and appears as a flattened, broad, dichotomously-branched plate, composed of several layers of cells. The upper and lower layers consist of colourless cells, and form a sort of epidermis. The upper epidermal layer has stomata, while the lower gives off root-like filaments, which attach it to the stratum on which it grows. The stomata are, by repeated division of the guard-cells, converted into canals. The central layer of cells contains green matter, and between the cellules there are large intercellular spaces, which communicate with the stomata on the upper surface. In what are usually termed the foliose Hepaticæ, such as Jungermanniæ, a distinct stem is visible bearing leaves. All are cellular, no differentiation occurring beyond a compacting of the peripheral layers of cells. The mode of branching is usually dichotomous.

In Fungi the vegetative organs consist of a mass of cellular filaments, anastomosing and branching in various ways, constituting the *mycelium* or *spawn* (fig. 95, *m*), from which diversely-shaped portions of cellular tissue are developed, forming *receptacles* for the support of the reproductive organs. The mycelium creeps along in or upon the stratum whence it is nourished, sending up here and there a receptacle. The structural elements which form these are colourless cellular filaments, or *hyphæ*, divided usually by many transverse septa. These sometimes combine to form a dense mass of parenchyma. In some cases the hyphæ of the mycelium are densely interwoven, and form masses of definite shape, the outer layer of which (pseudo-parenchymatous) forms a hard shell or skin; such a mass is termed a *sclerotium*. The reproductive receptacle formed from the mycelium is also composed of hyphæ. When there is only a single hypha the reproductive bodies are borne on the ends of its branches; but more usually the branches of the hyphæ bearing the reproductive bodies unite to form a flattened expansion, the *hymenium*. As they contain no chlorophyll, Fungi take up assimilated matter from other organisms, and therefore are frequently parasites. Fungi.

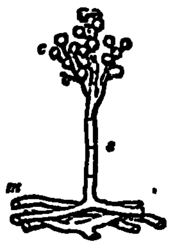

Fig. 95.

A species of Mould-fungus (*Botrytis*), consisting of a mycelium *m*, bearing a septate cellular stalk *s*, which branches at the apex, each division bearing a rounded spore *c*.

In Algæ the simplest forms present nothing but a cell-wall, containing a coloured protoplasmic substance, as in some Nostocaceæ. In some cases firmness is attained by deposition of silica as in Diatoms, or by lime carbonate as in Acetabularia. Lignification never occurs. More usually, however, the cells are combined into a tissue, but the forms which this may assume and the modes of combination are more various than in any other class of plants,—linear masses, strings, globes, laminæ, &c., being formed. There may be in some cases a slight differentiation into distinct organs. Thus, in some of the higher forms, as Fucaceæ, a distinct stem is formed, from which flattened thalli resembling leaf structures arise, and at the base root-like structures (*rhizoids*) are formed. These parts, however, have none of the internal structures which characterize higher plants, but consist entirely of cellular tissue. At most there is a condensation of cellular tissue at the periphery, forming an epidermis, and a similar condensation in the axis. The mode of branching amongst Algæ is either monopodial or dichotomous. Algæ.

In Lichens the thallus (fig. 96) consists of a *hyphal* element of anastomosing and interlacing filaments, amongst which are distributed rounded unicellular coloured bodies, the *gonidia* (fig. 97, *g*). These gonidia are either arranged Lichens.

in one layer in the thallus, which is then said to be *heteromerous* (the hypha layer being divided into a cortical and deeper part), or they are scattered equally throughout its substance and are *homœomerous*. The gonidia are separable, and may form independent plants. When they are being detached, the separation begins at the centre of the thallus, so that the middle of the Lichen becomes pulverulent, while its circumference may remain foliaceous or crustaceous. By the continuation of this process it sometimes happens that the whole Lichen becomes a mass of greenish or yellowish powder. The thallus may be crustaceous, in the form of an incrustation upon rocks, trees, &c., with which it becomes closely connected, as in Graphis; or it may be foliaceous, forming a flattened expansion easily detachable from the substratum to which it is connected by small root-like bodies or *rhizines*, as in Peltigera; or the lichen may be what is termed fruticose, *i.e.*, composed of a much-branched thallus rising from a single point of attachment, as in Usnea. Recent observations upon Lichens tend to show that they are in reality composed of two distinct organisms,—one, a Fungus, being the hyphal part, and the other, an Alga, the gonidial portion, and that the Fungus is parasitic upon the gonidia.

3. *Leaves and their Modifications.*

Leaves. In popular language all the green expanded organs borne upon an axis are designated leaves. Investigation, however, has shown that many other parts of a plant which externally appear very different from ordinary leaves are, in their essential particulars, very similar to them, and are in fact their morphological equivalents. Thus the scales on the bulb of the Onion, the various parts of the flower, &c., are all leaves. Assuming, then, that the structure ordinarily termed a leaf is the typical form, these latter are designated changed or *metamorphosed* leaves; and all structures morphologically equivalent with the leaf are included under the general term *phyllome* (leaf-structure). Leaves are produced as lateral outgrowths of the stem. This character, common to all leaves, distinguishes them from other organs. In the higher plants we can easily recognize the distinction between stem and leaf. Amongst the lower plants, however, it is found that a demarcation into stem and leaf is impossible, but that there is a structure which partakes of the characters of both,—such is a *thallome*. The leaves always arise from the outer portion of the primary meristem of the plant, and the tissues of the leaf are continuous with those of the stem. Every leaf originates as a simple cellular papilla, which consists of a development from the cortical layers covered by epidermis; and as growth proceeds, the fibro-vascular bundles of the stem are continued outwards, and finally expand and terminate in the leaf. The increase in length of the leaf by growth at the apex is usually of a limited nature. In some Ferns, however, there seems to be a provision for indefinite terminal growth, while in others this growth is periodically interrupted. It not unfrequently happens, especially amongst Monocotyledons, that after growth at the apex has ceased, it is continued at the base of the leaf, and in this way the length may be much increased. Amongst Dicotyledons this is very rare. In all cases the dimensions of the leaf are enlarged by interstitial growth of its parts.

Structure of leaves. The simplest leaf is found in some Mosses, where it consists of a single layer of cells. Usually it consists of several layers, and amongst vascular plants is distinguishable into an epidermis and a central parenchyma with fibro-vascular bundles distributed through it.

The *epidermis* (fig. 98, *es*, *ei*), composed of cells more or less compressed, has usually a different structure and aspect on the two surfaces of the leaf. It is chiefly on the epidermis of the lower surface (fig. 98, *ei*) that stomata, *st*, are produced, occupying spaces between the veins, and it is there also that hairs, *p*, usually occur. The lower epidermis is often of a dull or pale-green colour, soft, and easily detached. The upper epidermis is frequently smooth and shining, and sometimes becomes very hard and dense. Many tropical plants present on the upper surface of their leaves several layers of compressed epidermal cells. These appear to be essential for the preservation of moisture in the leaf. In leaves which float upon the surface of water, as those of the Water-lily, the upper epidermis alone possesses stomata.

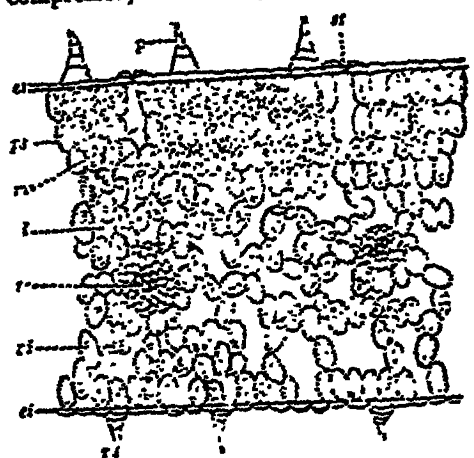

Fig. 98.

Section of a Melon-leaf, perpendicular to the surface. *es*, upper epidermis; *ei*, lower epidermis; *p*, hairs; *st*, stomata; *ps*, upper layers of parenchymatous cells; *pi*, lower layers of parenchymatous cells; *m*, meatus, or canals connected with stomata; they are sometimes called hypostomatic spaces; *l*, lacunæ, or cavities between the loose cells in the cavernous lower parenchyma; *fv*, bundles of fibro-vascular tissue, consisting of woody, dotted, spiral, and other vessels.

The *parenchyma* of the leaf is the cellular tissue surrounding the vessels, and enclosed within the epidermis (fig. 98, *ps*, *pi*). It has sometimes received the names of *diachyma*, *mesophyllum*, and *diploë*. It is formed of two distinct series of cells, each containing chlorophyll or green-coloured granules, but differing in form and arrangement. Below the epidermis of the upper side of the leaf there are one or two layers of oblong blunt cells, placed perpendicularly to the surface (fig. 98, *ps*), and applied so closely to each other as to leave only small intercellular spaces (fig. 98, *m*), except where stomata happen to be present. On the under side of the leaf the cells are irregular, often branched, and are arranged more or less horizontally (fig. 98, *pi*), leaving cavities between them, *l*, which often communicate with stomata. On this account the tissue has received the name of *cavernous*. In leaves having a very firm texture, as those of Coniferæ and Cycadaceæ, the cells of the parenchyma immediately beneath the epidermis are very much thickened and

elongated in a direction parallel to the surface of the leaf, so as to be fibre-like. These constitute a hypodermal layer, beneath which the chlorophyll cells of the parenchyma are densely packed together, and are elongated in a direction vertical to the surface of the leaf; this has been termed *palisade* tissue. The form and arrangement of the cells, however, depend much on the nature of the plant, and its exposure to light and air. Sometimes the arrangement of the cells on both sides of the leaf is similar, as occurs in leaves which have their edges presented to the sky. In very succulent plants the cells form a compact mass, and those in the centre are often colourless. In some cases the cellular tissue is deficient at certain points, giving rise to distinct holes in the leaf, as in Monstera Adansonii; such a leaf has been called *pertuse*. In Victoria regia perforations in the leaf seem to be subservient to the purposes of nutrition, by permitting the gases collected beneath the large expanded leaf to escape, and thus allowing its under surface to be brought into immediate contact with the water. The fibro-vascular system in the leaf constitutes the *venation*. The fibro-vascular bundles from the stem bend out into the leaf, and are there arranged in a definite manner. They usually form two layers, which may be separated by maceration. In *skeleton leaves*, or leaves in which the parenchyma is removed, these layers are well seen. In some leaves, as in the Barberry, the vessels forming the veins are hardened, producing spines without any parenchyma. The hardening of the extremities of the vascular tissue is the cause of the spiny margin of many leaves, such as the Holly, of the sharp-pointed leaves of Madder, and of mucronate leaves, or those having a blunt end with a hard projection in the centre.

Submerged leaves, or leaves which are developed under water, differ in structure from aerial leaves. They have usually no fibro-vascular system, but consist of a congeries of cells, which sometimes become elongated and compressed so as to resemble veins. They have a layer of compact cells on their surface, but no true epidermis, and no stomata. Their internal structure consists of cells, disposed irregularly, and sometimes leaving spaces which are filled with air for the purpose of floating the leaf. When exposed to the air these leaves easily part with their moisture, and become shrivelled and dry. In some instances there is only a network of filamentous-like cells formed, the spaces between which are not filled with parenchyma, giving a peculiar skeleton appearance to the leaf, as in Ouvirandra fenestralis (Lattice plant). Such a leaf has been called *fenestrate*. A leaf, whether aerial or submerged, generally consists of a flat expanded portion (fig. 99, *l*), called the *blade*, *limb*, or *lamina*, of a narrower portion called the *petiole* or *stalk* (fig. 99, *p*), and sometimes of a portion at the base of the petiole, which forms a *sheath* or *vagina* (fig. 99, *g*), or is developed in the form of leaflets, called *stipules* (fig. 123, *s*). The sheathing portion is sometimes incorporated with the stem, and is then called *tigellary*. These portions are not always present. The sheathing or stipulary portion is frequently wanting, and occasionally only one of the other two is developed. When a leaf has a distinct stalk it is called *petiolate*; when it has none, it is *sessile*, and if in this case it embraces the stem it is said to be *amplexicaul*. The part of the leaf next the petiole or the axis is the *base*, while the opposite extremity is the *apex*. The surfaces of the leaf are called the *paginæ*,

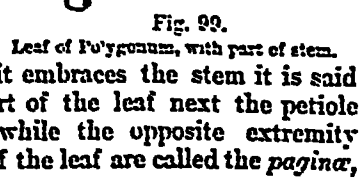

Fig. 99.
Leaf of Polygonum, with part of stem.

and its edges or margins form the *circumscription* of the leaf. The leaf is usually flattened and expanded horizontally, *i.e.*, at right angles to the longitudinal axis of the shoot, so that the upper pagina is directed towards the heavens, and the lower pagina towards the earth. In some cases leaves, as in Iris, or leaf-like petioles, as in Australian Acacias and Eucalypti, have their plane of expansion parallel to the axis of the shoot; or the leaf may have a cylindrical or polyhedral form, as in Mesembryanthemum. In other instances, as in Alströmeria, the leaf becomes twisted in its course, so that what is superior at one part becomes inferior at another. The upper angle formed between the leaf and the stem is called its *axil*, and everything arising at that point is called *axillary*. It is there that leaf-buds are usually developed. The leaf is sometimes articulated with the stem, and, when it falls off, a *scar* or *cicatricula* remains; at other times it is continuous with it, and then decays, while still attached to the axis. In their early state all leaves are continuous with the stem, and it is only in their after growth that articulations are formed. When leaves fall off annually they are called *deciduous*; when they remain for two or more years they are *persistent*, and the plant is called *evergreen*. The laminar portion of a leaf is occasionally articulated with the petiole, as in the Orange, and a joint at times exists between the vaginal or stipulary portion and the petiole.

Venation

The arrangement of the fibro-vascular system in the lamina constitutes the *venation* or *nervation*. In an ordinary leaf, as that of the Elm, there is observed a large central vein running from the base to the apex of the leaf, this is the *midrib* (fig. 100); it gives off veins laterally (*primary veins*), which either end in a curvature within the margin (*curve-veined*), as in Lilac and Belladonna, or go directly to the edge of the leaf (*feather-veined*), as in Elm (fig. 100) and Chestnut. If they are curved, then external veins and marginal veinlets are interspersed through the parenchyma external to the curvature. There are also other veins of less extent (*costal veins*) given off by the midrib, and these give origin to small *veinlets*. A leaf with only a single midrib is said to be *unicostate* (fig. 100). In some cases, as Sycamore and Cinnamon, in place of there being only a single midrib there are several large veins (ribs) of nearly equal size, which diverge from the point where the blade joins the petiole or stem, giving off lateral veins. The leaf in this case is *multicostate* (fig. 101). When there are three prominent ribs, as in Cinnamon and Cassia, the leaf is *tricostate*; when five, *quinquecostate*. When the midrib gives off two ribs a little above the base, the leaf becomes *triplicostate*; when it gives off five, *quintuplicostate*.

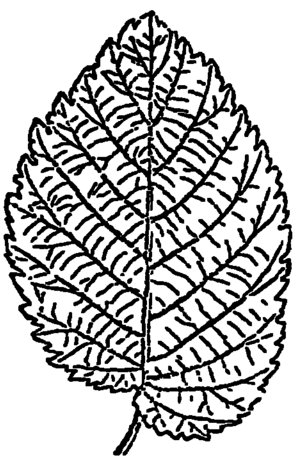

Fig. 100

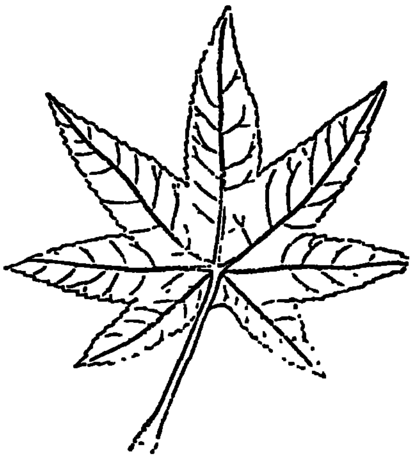

Fig. 101.

FIG. 100.—Leaf of *Ulmus effusa*. Reticulated venation; primary veins going to the margin, which is serrated. Leaf unequal at the base.

FIG. 101.—Multicostate divergent leaf of Castor-oil plant (*Ricinus communis*). It is palmately-cleft, and exhibits seven lobes at the margin. The petiole is inserted a little above the base, and hence the leaf is called peltate or shield-like.

In a leaf having many ribs they may converge towards the apex, as in Cinnamon, or they may diverge, as in Sycamore and the Castor-oil plant (fig. 101). Thus the primary veins give off secondary veins, and these in their turn give off tertiary veins, and so on until a complete network of vessels is produced, and those veins usually project on the under surface of the leaf. To a distribution of veins such as this the name of *reticulated* or *netted* venation has been applied. In the leaves of some plants there exists a midrib with large veins running nearly parallel to it from the base to the apex of the lamina, as in Grasses (fig. 102); or with veins diverging from the base of the lamina in more or less

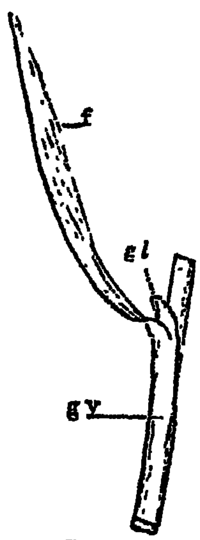

Fig. 102.

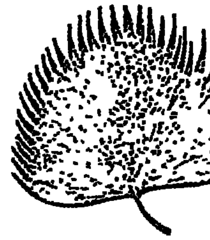

Fig. 103.

FIG. 102.—Stem of a Grass (*Poa*) with leaf. The sheathing petiole *gv* ending in a process *gl*, called a ligule; the blade of the leaf, *f*.
FIG. 103.—Leaf of Fan Palm (*Chamærops*), showing the veins running from the base to the margin, and not forming an angular net-work.

parallel lines, as in Fan Palms (fig. 103), or with veins coming off from it throughout its whole course, and running parallel to each other in a straight or curved direction towards the margin of the leaf, as in Plantain and Banana. In these cases the veins are often united by cross veinlets, which do not, however, form an angular network. Such leaves are said to be *parallel-veined*. The leaves of Monocotyledons have generally this kind of venation, while reticulated venation most usually occurs amongst Dicotyledons. Some plants, which in most points of their structure are Monocotyledonous, yet have reticulated venation. Such have been called Dictyogens. In vascular Acotyledonous plants there is frequently a tendency to fork exhibited by the fibro-vascular bundles in the leaf; and when this is the case we have *fork-veined* leaves. This is well seen in many Ferns. The distribution of the system of vessels in the leaf is usually easily traced, but in the case of succulent plants, as Hoya, Agave, Stonecrop, and Mesembryanthemum, the veins are obscure, and the leaves are said to be *hidden-veined*. In the cellular leaves of Mosses a median vein of several layers of cells is often visible, but as there are no fibro-vascular bundles present this is considered a false venation, and they are styled *veinless* (*Avenia*).

TABULAR ARRANGEMENT OF VENATION.

A.—Reticulated Venation.
- I. *Unicostate*. A single rib or costa in the middle (midrib).
  - 1. Primary veins coming off at different points of the midrib.
    - *a*. Veins ending in curvatures within the margin, and forming what have been called *true netted* leaves (Lilac).
    - *b*. Veins going directly to the margin and forming *feather-veined* leaves (Oak and Chestnut).
  - 2. Primary veins coming off along with the midrib from the base of the leaf.
- II. *Multicostate*. More than one rib. Authors usually give to these leaves the general name of *costate* or *ribbed*.
  - 1. *Convergent*. Ribs converging, running from base to apex in a curved manner, as in Cinnamon and Melastoma. There is occasionally an obscure rib running close to the edge of the leaf, and called intra-marginal, as in the Myrtle.
  - 2. *Divergent*. Ribs diverging or proceeding in a radiating manner, as in Sycamore, Vine, Geranium, Castor-oil plant.

B.—Parallel Venation.—The term parallel is not strictly applicable, for the veins often proceed in a radiating manner, but it is difficult to find a comprehensive term. This venation may be characterised as *not reticulated*.
- I. Veins proceeding transversely from midrib to margin, usually with convexity towards the midrib, as in Musa and Canna.
- II. Veins proceeding longitudinally from base to apex.
  - 1. Veins more or less convergent, as in Iris, Lilies, Grasses.
  - 2. Veins more or less divergent, as in Fan Palms.

C.—Furcate Venation. Veins dividing in a forked manner, as in the case of many Ferns.

In all plants, except Thallophytes, leaves are present at some period of their existence. In Cuscuta (Dodder), however, we have an exception. The forms assumed by leaves vary much, not only in different plants but in the same plant. It is only amongst the lower classes of plants,—Mosses, Characeæ, &c.,—that all the leaves on a plant are similar. As we pass up the scale of vegetable life we find them becoming more and more variable. The structures in ordinary language designated as leaves are considered so *par excellence*, and they are frequently spoken of as *foliage leaves*. In relation to their production on the stem we may observe that when they are small they are always produced in great number, and as they increase in size their number and rapidity of growth diminish correspondingly. The cellular process from the axis which develops into a leaf is simple and undivided; it rarely remains so, but in progress of growth becomes segmented in various ways, either longitudinally or laterally, or in both ways. By longitudinal segmentation we have a leaf formed consisting of vagina, petiole, and lamina; or one or other of these may be absent, and thus stalked, sessile, sheathing, &c., leaves are produced. Lateral segmentation affects the lamina, producing indentations, lobings, or fissuring of its margins. In this way two marked forms of leaf are produced—(1.) *Simple* form, in which the segmentation, however deeply it extends into the lamina, does not separate portions of the lamina which become articulated with the midrib or petiole; and (2.) *Compound* form, where portions of the lamina are separated as detached *leaflets* (*foliola*), which become articulated with the midrib or petiole. In simple leaves, then, there is never more than one articulation, which is at the point of their insertion on the stem. In compound leaves there are one or more articulations beyond the point of insertion on the stem. In both simple and compound leaves, according to the amount of segmentation and the mode of development of the parenchyma and direction of the fibro-vascular bundles, many forms are produced. Forms of leaves. Plate X.

Simple Leaves.—When the parenchyma is developed symmetrically on each side of the midrib or stalk, the leaf is *equal*; if otherwise, the leaf is *unequal* or *oblique* (fig. 100). If the margins are even and present no divisions, the leaf is *entire* (fig. 104); if there are slight projections of cellular or vascular tissue beyond the margin the leaf is not entire; when the projections are irregular and more or less pointed, the leaf is *dentate* or toothed; when they lie regularly over each other, like the teeth of a saw, the leaf is *serrate* (fig. 100); when they are rounded the leaf is *crenate*. If the divisions extend more deeply into the lamina than the margin, the leaf receives different names according to the nature of the segments; thus, when the divisions extend about half-way down (fig. 105), it is *cleft* (*fissus*), and its lines of separation are called *fissures*; when Simple leaves.

the divisions extend nearly to the base or to the midrib the leaf is *partite*, and its lines of separation are called *partitions.*

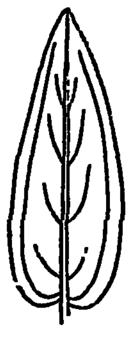

Fig. 104.

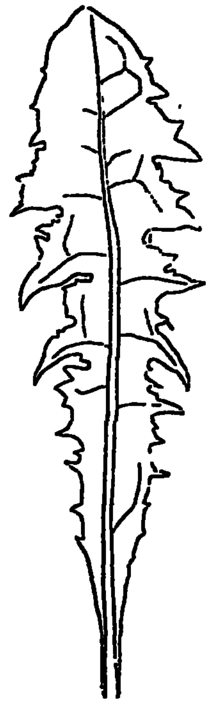

Fig. 105.

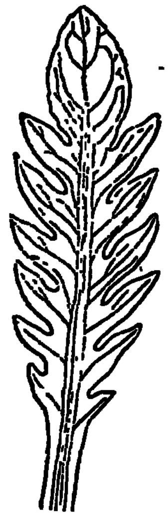

Fig. 106.

Fig. 104.—Ovate acute leaf of *Coriara myrtifolia*, one of the adulterations of senna. Besides the midrib there are two intra-marginal ribs which converge to the apex. The leaf is therefore tricostate.
Fig. 105.—Runcinate leaf of Dandelion (*Leontodon Taraxacum*). It is a pinnatifid leaf, with the divisions pointing towards the petiole.
Fig. 106.—Pinnatifid leaf of *Valeriana dioica*.

If these divisions take place in a simple *feather-veined* leaf it becomes either *pinnatifid* (fig. 106), when the segments extend to about the middle and are broad; or
ates I. *pectinate*, when they are narrow; or *pinnatipartite*, when
d VIII. the divisions extend nearly to the midrib. These primary divisions may be again subdivided in a similar manner, and thus a *feather-veined* leaf will become *bipinnatifid* or *bipinnatipartite;* and still further subdivisions give origin to *tripinnatifid* and *laciniated* leaves. If the divisions of a pinnatifid leaf are more or less triangular, and point downwards towards the base, the extremity of the leaf being undivided and triangular, the leaf is *runcinate* (fig.
ate IX. 105), as in the Dandelion. When the apex consists of a large rounded lobe, and the divisions, which are also more or less rounded, become gradually smaller towards the base, as in Barbarea, the leaf is called *lyrate*, from its resemblance to an ancient lyre. When there is a concavity on each side of a leaf, so as to make it resemble a violin, as in Rumex pulcher, it is called *panduriform*. The same kinds of divisions taking place in a simple leaf with *radiating* venation, give origin to *lobed*, *cleft*, and *partite* forms. When the divisions extend about half-way through the leaves, they may be *three-lobed*, *five-lobed*, *seven-lobed*, *many-lobed*, or *trifid*, *quinquefid*, *septemfid*, *multifid*, according to the number of the divisions. The name *palmate*, or *palmatifid* (fig. 101), is the general term applied to leaves with radiating venation, in which there are several lobes united by a broad expansion of parenchyma, like the
'late VI. palm of the hand, as in the Castor oil plant, Rheum palma-
g. 1. tum, and Papaw. The divisions of leaves with radiating venation may extend to near the base of the leaf, and the names *bipartite*, *tripartite*, *quinquepartite* (fig. 107), *septempartite*, *digitipartite* (Plate II. fig. 1), are given according as the partitions are two, three, five, seven, or more. In Drosera dichotoma bipartite and tripartite leaves are seen. The term *dissected* is applied to leaves with radiating venation, having numerous narrow divisions, as in Geranium dissectum.

When in a radiating leaf there are three primary partitions, and the two lateral lobes are again cleft, as in Helleborus

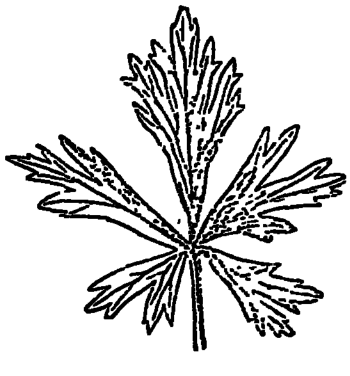

Fig. 107.

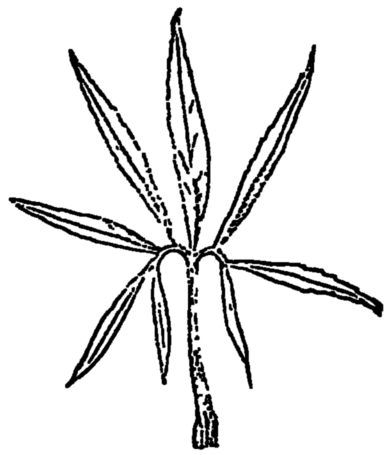

Fig. 108.

Fig. 107.—Five-partite leaf of Aconite. Such a leaf is sometimes called palmipartite, palmately-partite, or dissected. The venation is radiating, and the segments of the leaf are cuneate, and each of them is cleft and toothed at the apex
Fig. 108.—Pedate leaf of Stinking Hellebore (*Helleborus fœtidus*). The venation is radiating. It is a palmately-partite leaf, in which the lateral lobes are deeply divided. When the leaf hangs down it resembles the foot of a bird, and hence the name.

(fig. 108), the leaf is called *pedate* or *pedatifid*, from a fancied resemblance to the claw of a bird. In all the instances already alluded to the leaves have been considered as flat expansions, in which the ribs or veins spread out on the same plane with the stalk. In some cases, however, the veins spread at right angles to the stalk. If they do so equally on all sides, and are united by parenchyma, so that the stalk occupies the centre, the leaf becomes *orbicular*, as in Hydrocotyle; if unequally, so that the stalk is not in the centre, the leaf is *peltate*, as in Indian Cress (fig. 109). The edges or margins of orbicular and peltate leaves are often variously divided.

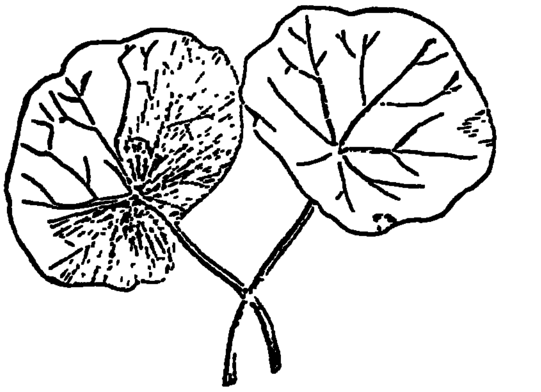

Fig. 109.

Fig. 110.

Fig. 109.—Peltate leaves of Indian Cress (*Tropæolum majus*).
Fig. 110.—Lanceolate leaf of a species of Senna.

Without attempting to notice all the forms of leaves, the following are enumerated as the most important. When the veins do not spread out, but run fron the apex with a narrow strip of parenchyma, *linear* or *acicular*, as in Pines and Firs. The hence called in Germany *Nadel-hölzer*, or When the veins diverge, those in the middle be and *the leaf tapering at each end* (fig. 110), *lanceolate*. If the middle veins exceed the otl and the ends are convex, the leaf is either *round*, *oval*, or *oblong* (fig. 111). If the veins at the base and the leaf narrows to the top, it is *ovate* or (fig. 104), as in Chickweed; if the apex is broa is *obovate*, or inversely egg-shaped (fig. 112). *cuneate* or wedge-shaped, in Saxifraga; *sp* spatula-like, having a broad rounded apex, a

down to the stalk, as in the Daisy; *subulate*, narrow and tapering like an awl; *acuminate*, or drawn out into a long point, as in Ficus religiosa; *mucronate*, with a hard stiff point or mucro at the apex. When the parenchyma is deficient at the *apex* so as to form two rounded lobes, the leaf is *obcordate* or inversely heart-shaped; when the deficiency is
Plate IV. very slight the leaf is called *emarginate* (fig. 112), as having a portion taken out of the margin; when the apex is merely flattened or slightly depressed the leaf is *retuse;* and when the apex ends abruptly in a straight margin, as in the Tulip-tree, the leaf is *truncate*. When the veins at the base of the lamina are prolonged downwards at an obtuse angle with the midrib, and rounded lobes are formed, as in

Fig. 111.

Fig. 112.

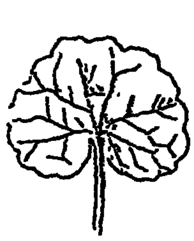

Fig. 113.

Fig. 114.

Fig. 111.—Oblong leaf of a species of Senna.
Fig. 112.—Emarginate leaf of a species of Senna. The leaf in its contour is somewhat obovate, or inversely egg-shaped, and its base is oblique.
Fig. 113.—Reniform leaf of *Nepeta Glechoma*, margin crenate.
Fig. 114.—Sagittate leaf of Convolvulus.

Dog-violet, the leaf is *cordate* or heart-shaped; it is kidney-shaped or *reniform* (fig. 113), when the apex is rounded as in Asarum. When the lobes are prolonged downwards and are acute, the leaf is *sagittate* (fig. 114); when they proceed at right angles, as in Rumex Acetosella, the leaf is *hastate* or halbert-shaped. When a simple leaf is divided at the base into two leaf-like appendages, it is called *auriculate*. When the veins spread out in various planes, and there is a large development of cellular tissue, so as to produce a succulent leaf, such forms occur as *conical, prismatical, ensiform* or sword-like, *acinaciform* or scimitar-shaped, and *dolabriform* or axe-shaped. When the development of parenchyma is such that it more than fills up the spaces between the veins, the margins become *wavy, crisp,* or *undulated*, as in Rumex crispus and Rheum undulatum. By cultivation the cellular tissue is often much increased, giving rise to the *curled* leaves of Greens, Savoys, Cresses, Lettuce, &c. In Rushes the shoots which act as leaves are often *terete*. They are either barren or bear flowers. Their cellular tissue is often stellate, and the shoots sometimes exhibit a peculiar spiral twisting. Amongst parallel veined leaves the margins are usually entire, especially when the veins converge.

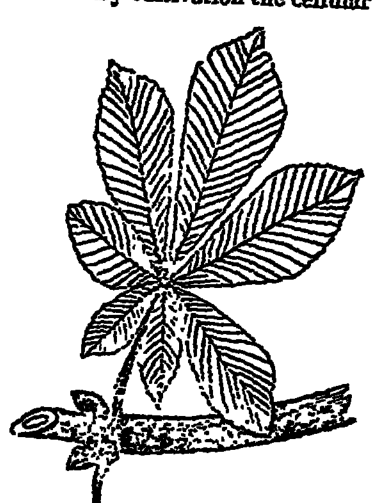

Fig. 115.

Septenate leaf of the Horse-chestnut (*Æsculus Hippocastanum*). Such leaves, especially when there are five leaflets, are called digitate.

Compound leaves. Compound leaves are those in which the divisions extend to the midrib or petiole, and the separated portions become each articulated with it, and receive the name of *foliola* or *leaflets*. The midrib, or petiole, has thus the appearance of a branch with separate leaves attached to it, but it is considered properly as one leaf, because in its earliest state it arises from the axis as a single piece, and its subsequent divisions in the form of leaflets are all in one plane. The leaflets are either sessile (fig. 115), or have stalks, called *petiolules* (fig. 116), according as the vascular bundles of the veins spread out or divaricate at once, or remain united for a certain length. Compound leaves have been classified according to the nature of the venation and the development of parenchyma. If we suppose that in a simple feather-veined unicostate leaf the divisions extend to the midrib, and each of the primary veins spreads out or branches, and becomes surrounded with parenchyma, and the leaflets thus formed become articulated to the petiole or midrib (fig. 116), the leaf becomes compound and

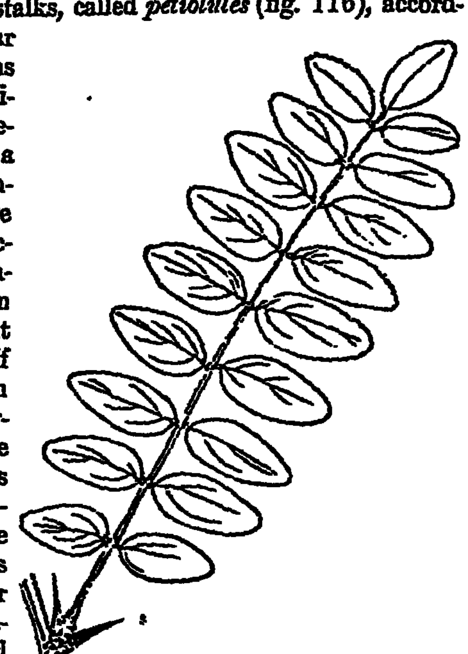

Fig. 116.

Impari-pinnate (unequally pinnate) leaf of Robinia. There are nine pairs of shortly-stalked leaflets (foliola, pinnæ), and an odd one at the extremity. At the base of the leaf stipules *s* are seen.

pinnate. If the midrib and primary veins are not covered Plate XV.
with parenchyma, while the *secondary* (or those coming off in a feather-like manner from the primary veins) are, and separate leaflets are thus formed which are articulated with the veins, the leaf is *bipinnate*. In this case the secondary veins form as it were partial petioles. A farther subdivision, in which the *tertiary* veins only are covered with parenchyma and have separate leaflets, gives *tripinnate* or *decompound* forms, in which case the tertiary veins form the partial petioles. A leaf divided still more is called *supradecompound*. When a pinnate leaf has one pair of leaflets it is *unijugate;* with two pairs, it is *bijugate;* with many pairs, *multijugate* (fig. 116). When a pinnate leaf ends in a pair of pinnæ it is *equally* or *abruptly pinnate* (pari-pinnate); when there is a single terminal leaflet (fig. 116), the leaf is *unequally pinnate* (impari-pinnate); when the leaflets or pinnæ are placed alternately on either side of the midrib, and not directly opposite to each other, the leaf is *alternately pinnate;* and when the pinnæ are of different sizes, the leaf is *interruptedly pinnate*. In the case of a simple multicostate leaf with radiating venation, if we suppose the ribs to be covered with parenchyma, so as to form separate leaflets, each of which is articulated to the petiole, the *digitate* form of compound leaf is produced; if there are three leaflets the form is *ternate* or *trifoliate;* Plate V
if four, *quaternate;* if five, *quinate;* if seven, *septenate;* and so on. If the three ribs of a ternate leaf subdivide each into three primary veins, which become covered with parenchyma so as to be separate articulated leaflets, the leaf is *biternate;* and if another threefold division takes place, it is *triternate*.

The *petiole* or leaf-stalk is the part which unites the limb Petiole.
or blade of the leaf to the stem (fig. 99, *p*). It is absent in *sessile* leaves, and this is also frequently the case when the vagina is present, as in Grasses. It consists of a mass of fibro-vascular bundles with a varying amount of cellular

tissue. The vessels are enclosed in an epidermal covering, with few stomata, and are more or less compressed. When the vascular bundles reach the base of the lamina they separate and spread out in various ways, as already described under venation. At the place where the petiole joins the stem there is frequently an articulation, or a constriction with a tendency to disunion, and at the same time there exists a swelling (fig. 117, *p*), called *pulvinus*, formed of cellular tissue, the cells of which exhibit the phenomenon

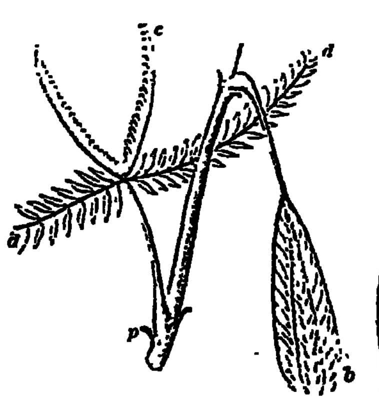

Fig. 117.

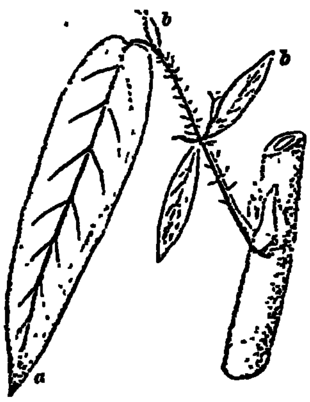

Fig. 118.

FIG. 117.—Branch and leaves of the Sensitive plant (*Mimosa pudica*), showing the petiole in its erect state, *a*, and in its depressed state, *b*; also the leaflets closed, *c*, and the leaflets expanded, *d*. Irritability resides in the pulvinus *p*, and in the struma.

FIG. 118.—A portion of the branch and leaf of the Moving plant of India (*Hedysarum* or *Desmodium gyrans*). The leaf is impari-pinnate, and often pinnately-trifoliate. The large leaflet or pinna, *a*; the smaller leaflets, *b*, of which there are either one or two pairs. The leaflets are in constant motion.

of irritability (figs. 117, 118). At the point where the petiole passes into the lamina, or where the midrib joins the leaflets of a compound leaf, there is occasionally a cellular dilatation called *struma*, and an articulation. In Mimosa pudica a sensitiveness is located in the pulvinus (fig. 117, *p*), which upon irritation induces a depression of the whole bipinnate leaf; a similar property exists in the struma at the base of the leaflets which fold upwards. In Desmodium gyrans (fig. 118) the pulvinus and struma have a similar power of causing movements of the large terminal leaflet and the two smaller lateral ones. In other cases the petiole is not articulated, but is continuous either with the stem, or with the sheath (vagina). The articulation or joint is by many considered as indicating a compound leaf, and hence the leaf of the Orange is considered as such, although it has an undivided lamina (fig. 119, *l*). In articulated leaves, the pulvinus may be attached either to the petiole or to the axis, and may fall with the leaf, or remain attached to the stem. When articulated leaves drop, their place is marked by a cicatrix or scar, seen below the bud in fig. 63. In this scar the remains of the vascular bundles *c* are seen; and its form furnishes characters by which particular kinds of trees may be known when not in leaf. In the case of many Palms and Tree-ferns the scars or cicatrices of the leaves are very conspicuous. In fossil plants important characters are founded on them.

When there is no articulation between the petiole and the stem, as is the case with many Monocotyledons, the leaf is continuous with the axis, and is not deciduous, but withers on the stalk. In many Liliaceous plants the leaves during their decay continue attached to the plants. The petiole varies in length, being usually shorter than the lamina, but sometimes much longer. In some Palms it is 15 or 20 feet long, and is so firm as to be used for poles or walking-sticks. In general, the petiole is more or less rounded in its form, the upper surface being flattened or grooved. Sometimes it is compressed laterally, as in the Aspen, and to this peculiarity the trembling of the leaves of this tree is attributed. In aquatic plants the leaf-stalk is sometimes distended with air, as in Pontederia and Trapa, so as to float the leaf. At other times it is *winged*, and is either leafy, as in the Orange (fig. 119, *p*), Lemon, and Dionæa (fig. 46, *p*), or pitcher-like, as in the Pitcher-plant

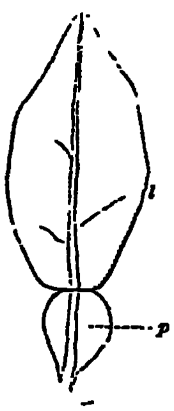

Fig. 119.

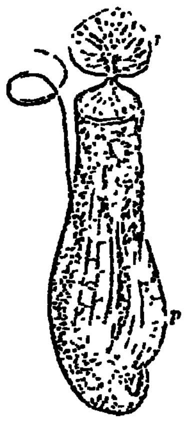

Fig. 120.

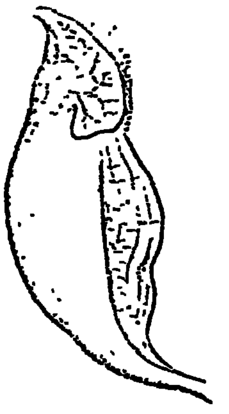

Fig. 121.

FIG. 119.—Leaf of Orange (*Citrus Aurantium*), showing a winged leafy petiole *p*, which is articulated to the lamina *l*. It is considered a compound leaf, having only one leaflet.

FIG. 120.—Pitcher of a species of Pitcher-plant (*Nepenthes distillatoria*). It is supposed to be formed by a folded petiole *p*, the edges of which are united. The lid *l* at the top is supposed to represent the lamina, united by articulation to the pitcher.

FIG. 121.—Pitcher (*ascidium*) of a species of Side-saddle plant (*Sarracenia purpurea*). The pitcher is supposed to be formed by the folded petiole, which is prolonged.

(fig. 120, *p*) and Sarracenia (fig. 121). Leafy petioles are occasionally united to the axis for some extent, and thus become *decurrent*. In some Australian Acacias, and in some species of Oxalis and Bupleurum, the petiole is flattened in a vertical direction, the vascular bundles separating immediately after quitting the stem, and running nearly parallel from base to apex. This kind of petiole (fig. 122, *p*) has been called *phyllodium*. In these plants the laminæ or blades of the leaves are pinnate, bipinnate, or ternate, and are produced at the extremities of the phyllodia in a horizontal direction; but in many instances they are not developed, and the phyllodium serves the purpose of a leaf. Hence some Acacias are called leafless. These phyllodia, by their vertical position and their peculiar

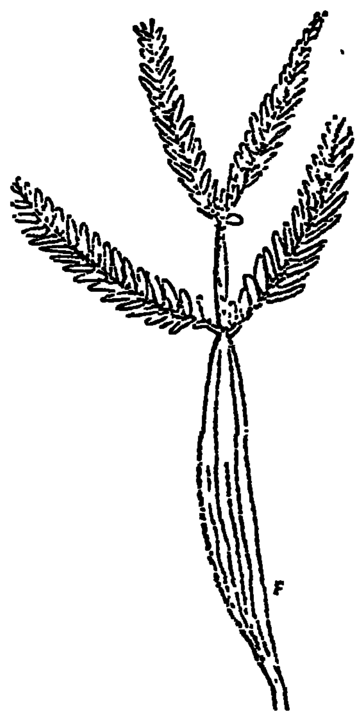

Fig. 122.

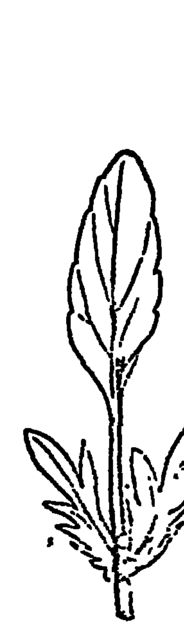

Fig. 123.

FIG. 122.—Leaf of an Acacia (*Acacia* [illegible]), showing a flattened leaf-like petiole *p*, called a phyllodium, with straight venation, and a bipinnate lamina *l*.

FIG. 123.—Leaf of Pansy, *l*, separated from the stem; the lyrato-pinnatifid stipules *s* are distinctly visible, and their lateral position is seen.

form, give a remarkable aspect to vegetation. On the same Acacia there occur leaves with the petiole and lamina

perfect; others having the petiole slightly expanded or winged, and the lamina imperfectly developed; and others in which there is no lamina, and the petiole becomes large and broad. Some petioles, in place of ending in a lamina become changed into a delicate filiform body, a *tendril* or *cirrus*, so as to enable the plant to climb. In many leaves interposed betwixt the petiole and the stem, or, in sessile leaves, betwixt the lamina and the stem, an expansion of the foliar tissue takes place, so that a *sheath* (*vagina*) is formed, which embraces the whole or part of the circumference of the stem (fig. 102, *gv*). This sheath is comparatively rare in Dicotyledons, but is seen in

Plate VII. Umbelliferous plants, where it constitutes the *pericladium*, and in the Rhubarb order, where it is large and membranous, and has received the name of *ochrea* or boot. It is much more common amongst Monocotyledons. In Palms it forms a kind of network, to which the name of *reticulum* has been given. In Sedges the sheath forms a complete investment of the stem, whilst in Grasses (fig. 102) it is split on one side. In the latter plants there is also a membranous outgrowth at right angles to the median plane of the leaf from the point where the sheath passes into the lamina (there being no petiole). To this structure the name of *ligule* (fig. 102, *gl*) has been given. It is of various dimensions, and thus gives a character to the plants.

Stipules. In leaves in which no sheath is produced we not unfrequently find small foliar organs at the base of the petiole. These have been denominated *stipules* (fig. 123, *s*). The stipules are often two in number, and they are important as supplying characters in certain natural orders. Thus they occur in the Pea and Bean family, in Rosaceous plants, and the Cinchona bark family. They are not common in Dicotyledons with opposite leaves. Plants having stipules are called *stipulate;* those having none are *exstipulate*. Stipules are formed by some of the vascular bundles diverging as they leave the stem, and becoming covered with parenchyma, so as to resemble true leaves. Like leaves they are large or small, entire or divided, deciduous or persistent, articulated or non-articulated. They are not usually of the same form as the ordinary foliage leaves of the plant, from which they are distinguished by their lateral position at the base of the petiole. In the Pansy (fig. 123) the true leaves *l* are stalked and crenate, while the stipules *s* are large, sessile, and pinnatifid. In Lathyrus Aphaca, and some other plants, the true pinnate leaves are abortive, the petiole forms a tendril, and the stipules alone are developed, performing the office of leaves. When stipules are attached separately to the stem at the base of the leaf, they are called *caulinary*, as in Salix aurita. When stipulate leaves are opposite to each other, at the same height on the stem, it occasionally happens that the stipules on the two sides unite wholly or partially, so as to form an *interpetiolary* or *interfoliar* stipule, as in Cinchona and in Ipecacuan. In the case of alternate leaves, the stipules at the base of each leaf are sometimes united to the petiole and to each other, so as to form an *adnate*, *adherent*, or *petiolary* stipule, as in the Rose, or an *axillary* stipule, as in Houttuynia cordata. In other instances the stipules unite together on the side of the stem opposite the leaf, and become *synochreate*, as in Astragalus. This so-called union or adhesion of stipules is not an accidental adhesion taking place after they have been developed. In these cases the parts never were separate; from the first they are developed as one portion. In the development of the leaf the stipules frequently play a most important part. They begin to be formed after the origin of the leaves, but grow much more rapidly than the leaves, and in this way they arch over the young leaves and form protective chambers wherein the parts of the leaf may develop. In Ficus, Magnolia, and Potamogeton they are very large and completely envelop the young leaf-bud. The stipules are sometimes so minute as to be scarcely distinguishable without the aid of a lens, and so fugacious as to be visible only in the very young state of the leaf. They may assume a hard and spiny character, as in Robinia Pseudacacia, or may be cirrose, as in Smilax, where each stipule is represented by a tendril; while in Cucurbitaceæ there is only one cirrose stipule. At the base of the leaflets or foliola of a compound leaf, small stipules are occasionally produced, to which some have given the name of *stipels*.

Variations in the structure and forms of leaves and leaf-stalks are produced by the increased development of cellular tissue, by the abortion or degeneration of parts, by the multiplication or repetition of parts, and by adhesion. Abnormalities. When cellular tissue is developed to a great extent, leaves become succulent and occasionally assume a crisp or curled appearance. Such changes take place naturally, but they are often increased by the art of the gardener, and the object of many horticultural operations is to increase the bulk and succulence of leaves. It is in this way that Cabbages and Savoys are rendered more delicate and nutritious. By a deficiency in development of parenchyma and an increase in the fibro-vascular tissue, leaves are liable to become hardened and spinescent. The leaves of Barberry and of some species of Astragalus, and the stipules of the False Acacia (Robinia) are spiny. To the same cause is attributed the spiny margin of the Holly-leaf. In the Gooseberry, the swelling (pulvinus) at the base of the petiole, and below the leaf, assumes a spinose character. Changes in the appearances of leaves are produced by adhesions and foldings of various kinds. When two lobes at the base of a leaf are prolonged beyond the stem and unite (fig. 124), the leaf is *perfoliate*, the stem appearing to pass through it, as in Bupleurum perfoliatum and Chlora perfoliata; when two leaves unite by their bases they become *connate* (fig. 125), as in Lonicera Caprifolium;

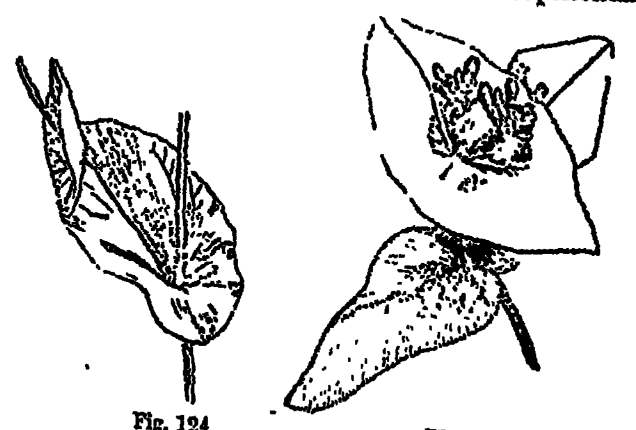

Fig. 124. Fig. 125.

FIG. 124.—Perfoliate leaf of a species of Hare's-ear (*Bupleurum rotundifolium*). The two lobes at the base of the leaf are united, so that the stalk appears to come through the leaf.
FIG. 125.—Connate leaves of a species of Honeysuckle (*Lonicera Caprifolium*). Two leaves are united by their bases.

and when leaves adhere to the stem, forming a sort of winged or leafy appendage, they are *decurrent*, as in Thistles. The formation of peltate and orbicular leaves has been traced to the union of the lobes of a cleft leaf. In the leaf of the Victoria regia the transformation may be traced during germination. The first leaves produced by the young plant are linear, the second are sagittate and hastate, the third are rounded-cordate, and the next are orbicular. The cleft indicating the union of the lobes remains in the large leaves. The parts of the leaf are frequently transformed into *tendrils* (*cirri*), with the view of enabling the plants to twine round others for support. In Leguminous plants (the Pea tribe) the pinnæ are frequently cirrose. When tendrils occupy the place of leaves, and Tendrils.

appear as a continuation of the leaf-stalk, they are called *petiolary*, as in Lathyrus Aphaca, in which the stipules perform the function of true leaves. In Flagellaria Indica, Gloriosa superba, Anthericum cirrhatum, and Albuca cirrhata, the midrib of the leaf ends in a tendril. In Smilax there are two stipulary tendrils, while in the Cucumber tribe there is a single one at the base of each leaf. In the Passion-flower the lateral leaf-buds, and in the Vine the terminal ones, become tendrils. In the Vanille plant (*Vanilla aromatica*) the tendrils are produced opposite the leaves, until the plant gains the top of the trees by which it is supported,—the upper tendrils being then developed as leaves. The midrib is sometimes prolonged in a cup-like or funnel-shaped form; this is occasionally seen in the common Cabbage, and seems to depend on the vascular bundles of the midrib spreading out at their extremity in a radiating manner, and becoming covered with parenchyma in such a way as to form a hollow cavity in the centre.

The vascular bundles and cellular tissue are sometimes developed in such a way as to form a circle, with a hollow in the centre, and thus give rise to what are called *fistular* or hollow leaves, as in the Onion, and to *ascidia* or *pitchers*.

em. Pitchers are formed either by petioles or by laminæ, and they are composed of one or more leaves. In Sarracenia (fig. 121) and Heliamphora, the pitcher is composed apparently of the petiole of the leaf. In Nepenthes (fig. 120) and perhaps in Cephalotus, while the folding of a winged petiole *p* forms the pitcher, the lid *l*, which is united by an articulation, corresponds to the lamina. This kind of ascidium is called *calyptrimorphous*, and may be considered as formed by a leaf, such as that of the Orange (fig. 119); the lamina *l* being articulated to the petiole *p*, which, when folded, forms the pitcher. In Dischidia Rafflesiana, a climbing plant of India, the pitchers are formed by the lamina of the leaf, and have an open orifice into which the rootlets at the upper part of the plant enter. These pitchers would seem, therefore, to contain a supply of fluid for the nourishment of the upper branches of the plant. In Utricularia the leaves form sacs called *ampullæ*. Some suppose that pitchers are not due to folding and adhesion, but that they are produced by a hollowing out of

s. the extremity of the stalk. In some cases the leaves are reduced to mere *scales*; they are then frequently called *cataphyllary* leaves. They are produced abundantly upon underground shoots. In parasites (Lathræa, Orobanche), and in plants growing on decaying vegetable matter (*Saprophytes*), in which no chlorophyll is formed, these scales are the only leaves produced. In Pinus the only leaves produced on the main stem and the lateral shoots are scales, the acicular leaves of the tree growing from axillary

e XV. shoots. In Cycas whorls of scales alternate with large pinnate leaves. In many plants, as already noticed, phyllodia or stipules perform the function of leaves. The production of leaf-buds from leaves has already been noticed. Such leaves are termed *proliferous*. In Bryophyllum (fig. 67) this is a common occurrence, and it is met with in many plants of the order Gesneraceæ. The leaf of Venus's Fly-trap (Dionæa muscipula, fig. 46), when cut off and placed in damp moss, with a pan of water underneath and a bell-glass for a cover, has produced buds from which young plants were obtained. Some species of Saxifrage and of Ferns also produce buds on their leaves and fronds. In Nymphæa micrantha buds appear at the upper part of the petiole.

ves in otyle- s. Amongst Dicotyledons we have leaves which present the greatest amount of variation in structure and form. The venation is reticulated. They are frequently articulated, exhibit divisions at their margin, and become truly compound. There are, no doubt, instances in which the veins proceed in a parallel manner, but this will be found to occur chiefly in cases where the petiole may be considered as occupying the place of the leaf. Examples of this kind are seen in Acacias (fig. 122). Dicotyledons rarely have a sheath developed, but stipules are very commonly present.

Leaves in Monocotyledons. In Monocotyledons the leaves do not present an angular network of vessels, nor do they, as a rule, exhibit divisions on their margin. Exceptions to this occur in some plants, as Tamus and Dioscorea, which have been called Dictyogens by Lindley, on account of their somewhat netted venation; and in Palms, in which, although the leaves are entire at first, they afterwards become split into various lobes. They are rarely stipulate, and very frequently have a sheath at their base. The petiole is often absent, and a sheathing ligule takes its place. The leaves are often continuous with the stem. In some aquatic Monocotyledons the submerged and floating leaves are narrow, like petioles, while those growing erect above the water expand. This is seen in Sagittaria sagittifolia, in which the erect leaves assume an arrow-like shape.

Leaves in Acotyledons. In Acotyledons the leaves vary much, being entire or divided, stalked or sessile, often feather-veined, occasionally with radiating venation, the extremities of the veins being forked. In Ferns the leaf (frond) is usually stalked, with frequently a much-divided lamina, remarkable for the prolonged growth at the apex, and in the young state usually covered with curious flattened hairs (*paleæ*). In Equisetaceæ the leaves are sheathing cylinders embracing successive internodes of the stem, and subsequently splitting at the top into few or many teeth. In Lycopodiaceæ the leaves vary from mere rudimentary scales, as in Psilotum, to the flattened acuminate leaf of Selaginella, with only a single fibro-vascular bundle, and then to the more complicated form in Isoetes, in which the longest leaves in the order occur, and these have a sheathing basal part and an upper lamina. On the face of the sheathing part is a depression or *fovea*, in which rests the sporangium, the margin of it rising as a thin membranous outgrowth, the *velum*. Above the fovea, and separated from it by a saddle-like ridge, lies a smaller depression the *foveola*, the lower margin of which forms a lip, the *labium*, and from its bottom is prolonged beyond the foveola an apiculate membranous structure, which is termed the *ligule*. In Mosses we have the simplest form of leaf, composed of one or more layers of cells, sometimes the central ones being more or less compacted and forming a median vein.

Phyllotaxis. Leaves occupy various positions on the stem and branches, and have received different names according to their situation. Thus leaves arising from the crown of the root, as in the Primrose, are called *radical*; those on the stem are *cauline*; on the branches, *ramal*; on flower-stalks, *floral* leaves. The first leaves developed are denominated *seminal* leaves or *cotyledons*, and those which succeed are *primordial*. The arrangement of the leaves on the axis and its appendages is called *phyllotaxis*. In their arrangement leaves follow a definite order. It has been stated already that there are regular *nodes* or points on the stem at which leaves appear, and that the part of the stem between the nodes is the *internode*. Each node is capable of giving origin to a leaf. Occasionally several nodes are approximated so as to form as it were one, and then several leaves may be produced at the same height on the stem. When two leaves are thus produced, one on each side of the stem or axis, and at the same level, they are called *opposite* (fig. 126); when more than two are produced (fig. 127), they are *verticillate*, and the circle of leaves is then called a *verticil* or *whorl*. When the zone of the axis which produces the circle of leaves is transverse from its origin, the whorl is a *true* one; but when the zone is the result of unequal development or of displacement the whorl is *spurious*. Again, in each whorl the leaves may be all

formed together, and a *simultaneous* whorl results; or they may be formed one after the other, as in Characeæ, when a *successive* whorl is formed. When leaves are opposite, each successive pair may be placed at right angles to the pair immediately preceding. They are then said to *decussate*, following thus a law of alternation. The same occurs

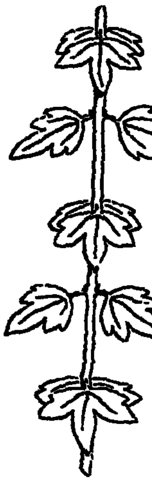

Fig. 126.

Fig. 127.

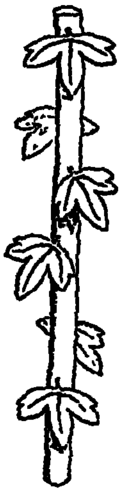

Fig. 128.

FIG 126.—A stem with opposite leaves The pairs are placed at right angles alternately, or in what is called a decussate manner. In the lowest pair one leaf is in front and the other at the back; in the second pair the leaves are placed laterally, and so on.

FIG 127—Verticillate or whorled leaves of a species of Madder There are five leaves in the verticil or whorl.

FIG 128.—A stem with alternate leaves, arranged in a pentastichous or quincuncial manner. The sixth leaf is directly above the first, and commences the second cycle. The fraction of the circumference of the stem expressing the divergence of the leaves is two-fifths.

in the verticillate arrangement, the leaves of each whorl rarely being *superposed* on those of the whorl next it, as on the branches of Chara, but usually alternating so that each leaf in a whorl occupies the space between two leaves of the whorl next to it. There are considerable irregularities, however, in this respect, and the number of leaves in different whorls is not always uniform, as may be seen in Lysimachia vulgaris. When a single leaf is produced at a node, and the nodes are separated so that each leaf is placed at a different height on the stem, the leaves are *alternate* (fig. 128). A plane passing through the point of insertion of the leaf in the node, dividing the leaf into two similar halves, is the median plane of the leaf; and when the leaves are arranged alternately on an axis so that their median planes coincide they form a straight row or *orthostichy* On every axis there are usually two or more orthostichies. The leaves in such a case are said to be rectiserial. In fig. 129, leaf 1 arises from a node *n*; leaf 2 is separated by

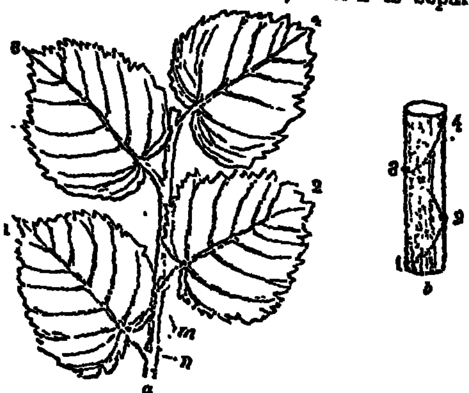

Fig. 129.

Portion of a branch of a Lime tree, with four leaves arranged in a distichous manner, or in two rows *a*, the branch with the leaves numbered in their order *n* being the node, and *m* the internode or merithal; *b* is a magnified representation of the branch, showing the cicatrices of the leaves and their spiral arrangement, which is expressed by the fraction ½ or one turn of the spiral for two internodes.

an internode *m*, and is placed to the right or left; while leaf 3 is situated directly above leaf 1. In this case, then, there are two orthostichies, and the arrangement is said to be *distichous*. When the fourth leaf is directly above the first, the arrangement is *tristichous*. The same arrangement continues throughout the branch, so that in the latter case the 7th leaf is above the 4th, the 10th above the 7th; also the 5th above the 2d, the 6th above the 3d, and so on. The size of the angle between the median planes of two consecutive leaves in an alternate arrangement is their *divergence*; and it is expressed in fractions of the circumference of the axis which is supposed to be a circle. In a regularly-formed straight branch covered with leaves, if a thread is passed from one to the other, turning always in the same direction, a spiral is described, and a certain number of leaves and of complete turns occur before reaching the leaf directly above that from which the enumeration commenced. If this arrangement is expressed by a fraction, the numerator of which indicates the number of turns, and the denominator the number of internodes in the spiral cycle, the fraction will be found to represent the angle of divergence of the consecutive leaves on the axis. Thus, in fig. 130, *a*, *b*, the cycle consists of five leaves, the 6th leaf being placed vertically over the 1st, the 7th over the 2d, and so on; while the number of turns between the 1st and 6th leaf is two; hence this arrangement is indicated by the fraction $\frac{2}{5}$. In other words, the distance or divergence between the first and second leaf, expressed in parts of a circle, is $\frac{2}{5}$ of a circle, or $360° \div \frac{2}{5} = 144°$. In fig. 129, *a*, *b*, the spiral is $\frac{1}{2}$, *i.e.*, one turn and two leaves; the third leaf being placed vertically over the first, and the divergence between the first and second leaf being one-half the circumference of a circle, $360° \div \frac{1}{2} = 180°$. Again, in a tristichous arrangement the number is $\frac{1}{3}$, or one turn and three leaves, the angular divergence being 120°.

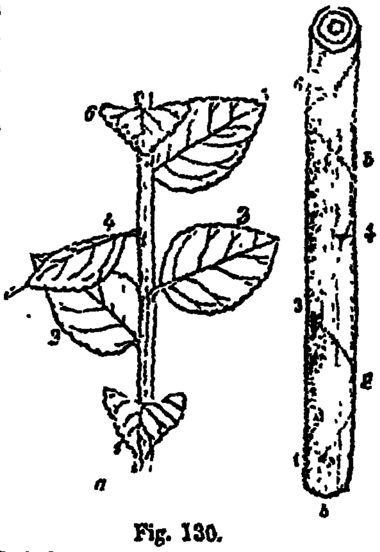

Fig. 130.

Part of a branch of a Cherry with six leaves, the sixth being placed vertically over the first, after two turns of the spiral. This is expressed by two-fifths, or the quincunx. *a*, the branch, with the leaves numbered in order; *b*, a magnified representation of the branch, showing the cicatrices of the leaves or their points of insertion, and their spiral arrangement.

By this means we have a convenient mode of expressing on paper the exact position of the leaves upon an axis. And in many cases such a mode of expression is of excellent service in enabling us readily to understand the relations of the leaves. The divergences may also be represented diagrammatically on a horizontal projection of the vertical axis, as in fig. 131. Here the outermost *circle* represents a section of that portion of the axis bearing the lowest leaf, the innermost represents the highest. The broad dark lines represent the leaves, and they are numbered according to their age and position. It will

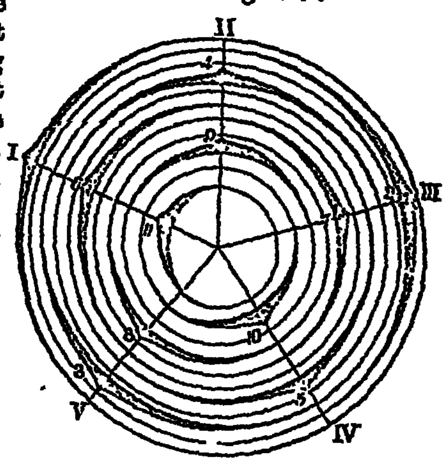

Fig. 131.

Diagram of a phyllotaxis represented by the fraction 2-5ths. (*Sachs.*)

be seen at once that the leaves are arranged in orthostichies marked I.–V., and that these divide the circumference into five equal portions. But the divergence between leaf 1 and leaf 2 is equal to $\frac{2}{5}$ths of the circumference, and the same is the case between 2 and 3, 3 and 4, &c. The divergence, then, is $\frac{2}{5}$, and from this we learn that, starting from any leaf on the axis, we must pass twice round the stem in a spiral through five leaves before reaching one directly over that with which we started. When the leaves or scales are alternate, and run in a single series, they are *unijugate;* when the leaves are opposite, and there are two series, the arrangement is *bijugate;* while in the case of whorled leaves the arrangement may be *trijugate* or *quadrijugate.* The line which, winding round an axis either to the right or to the left, passes through the points of insertion of all the leaves on the axis is termed the *genetic* or *generating spiral;* and that margin of each leaf which is towards the direction from which the spiral proceeds is the *kathodic* side, the other margin facing the point whither the spiral passes being the *anodic* side.

In cases where the internodes are very short, and the leaves are closely applied to each other, as in the House-leek, it is difficult to trace the *generating spiral.* Thus, in fig. 132 there are thirteen leaves which are numbered in their order, and five turns of the spiral marked by circles in the centre

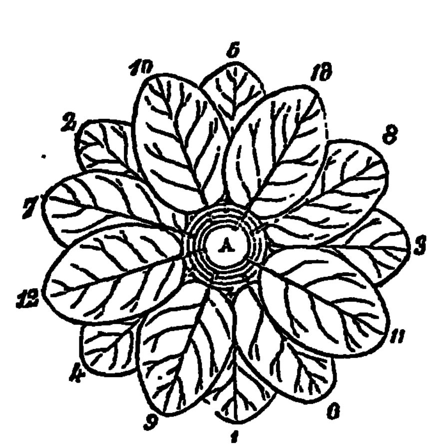

Fig. 132.

Fig. 133.

FIG. 132.—Cycle of thirteen leaves placed closely together so as to form a rosette. as in Sempervivum. A is the very short axis to which the leaves are attached, The leaves are numbered in their order, from below upwards. The circles in the centre indicate the five turns of the spiral, and show the insertion of each of the leaves. The divergence is expressed by the fraction 5-13ths.

FIG. 133.—Cone of *Abies alba* with the scales or modified leaves numbered in the order of their arrangement on the axis of the cone. The lines indicate a rectilinear series of scales, and two lateral secondary spirals, one turning from left to right, the other from right to left.

($\frac{5}{13}$ indicating the arrangement); but this could not be detected at once. So also in Fir cones (fig. 133), which are composed of scales or modified leaves, the generating spiral cannot be determined easily. But in such cases a series of *secondary spirals* or *parastichies* are seen running parallel with each other both right and left, which to a certain extent conceal the genetic spiral. Thus, in fig. 133, it will be found that there are five secondary spirals running towards the right and parallel to each other, the first passing through the scales 1, 6, 11, 16, &c.; the second through 9, 14, 19, 24, &c.; the third through 17, 22, 27, 32, 37, &c.; the fourth through 30, 35, 40, 45, &c.; the fifth through 43, 48, 53, &c. The number of these secondary spirals indicates the number of scales intervening between every two scales in each of these spirals, the common difference being five. Again, it will be found on examination that there are secondary spirals running to the left, in which the common difference between every two scales is eight, and that this corresponds to the number of secondary spirals, the first of which passes through the scales 1, 9, 17, &c.; the second through 6, 14, 22, 30, &c.; the third through 3, 11, 19, 27, 35, 43, and so on. Thus it is that, by counting the secondary spirals, all the scales may be numbered, and by this means the generating spiral may be discovered. From the number of secondary spirals the angle of divergence may be easily calculated, the sum of those which wind in both directions giving the denominator of the fraction, while the smaller of the two numbers representing those winding in each direction is the numerator. Thus in the instance last mentioned the angular divergence is $\frac{5}{13}$. In the cone of the American larch (fig. 134) there is a quincuncial arrangement of scales marked by the fraction $\frac{2}{5}$. There are five vertical ranks, as marked in the tabular numerical view at the side of the cone, which represents the unwound surface of the cone, viz., 2, 7, 12; 4, 9, 14; 1, 6, 11; 3, 8, 13; 5, 10, 15,—the common difference in each row being 5. On looking at the cone we find also parallel oblique ranks, two of which, ascending to the left, are marked by the numbers 1, 3, 5, which, if the diagram is coiled round a cylinder, continue in the numbers 7, 9, 11, 13, 15; and 2, 4, 6, 8, 10, continued into 12, 14. There are thus two left-handed spirals, with 2 as the common difference in the numbering of the scales. Again, three oblique parallel spirals ascend to the right, marked by the numbers 1, 4, 7, running into 10, 13; 3, 6, 9, 12, going on to 15; and 5, 8, 11, 14; here the common difference in the numbering of the scales is 3, corresponding with the oblique right-handed spirals.

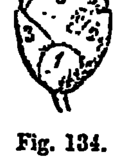

Fig. 134.

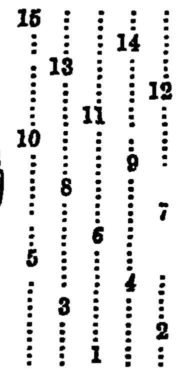

Cone of a species of Larch (*Larix microcarpa*). The surface of the cone is supposed to be unwound and the scales numbered so far as seen. The arrangement is 2-5ths, in the five-ranked series.

All the constant divergences found in phyllotaxis may be represented as successive convergents of the continued fraction

$$\frac{1}{a + 1 + 1 + 1 + 1, \&c.,}$$

where a may have the values 1, 2, 3, 4, &c.

The actual fractions thus resulting are—

$$\begin{aligned} \text{when } a &= 1, \ldots \tfrac{1}{2},\ \tfrac{2}{3},\ \tfrac{3}{5},\ \tfrac{5}{8},\ \tfrac{8}{13},\ \&c. \\ a &= 2, \ldots \tfrac{1}{2},\ \tfrac{1}{3},\ \tfrac{2}{5},\ \tfrac{3}{8},\ \tfrac{5}{13},\ \&c. \\ a &= 3, \ldots \tfrac{1}{3},\ \tfrac{1}{4},\ \tfrac{2}{7},\ \tfrac{3}{11},\ \tfrac{5}{18},\ \&c. \\ a &= 4, \ldots \tfrac{1}{4},\ \tfrac{1}{5},\ \tfrac{2}{9},\ \tfrac{3}{14},\ \tfrac{5}{23},\ \&c. \end{aligned}$$

The spiral is not always constant throughout the whole length of an axis. The angle of divergence may alter either abruptly or gradually, and the phyllotaxis thus becomes very complicated. This change may be brought about by arrest of development, by increased development of parts, or by a torsion of the axis. The former are exemplified in many Crassulaceæ and Aloes. The latter is seen well in the Screw pine (Pandanus). In the bud of the screw pine the leaves are arranged in three orthostichies with the phyllotaxis $\frac{1}{3}$, but by torsion the developed leaves become arranged in three strong spiral rows running round the stem. These causes of change in phyllotaxis are also well exemplified in the alteration of an opposite or verticillate arrangement to an alternate, and *vice versa;* thus the effect of interruption of growth, in causing alternate leaves to become opposite and verticillate, can be distinctly shown in Rhododendron ponticum. Again, parts which are usually opposite or verticillate become alternate by the vigorous development of the axis, as in Hippuris, and also in Lysimachia vulgaris, where on different parts of the same stem there may be seen alternate, opposite, and

verticillate leaves. When the interruption to development takes place at the end of a branch, the leaves become *fasciculate* or clustered, as in the Larch. The primitive or generating spiral may pass either from right to left or from left to right. It sometimes follows a different direction in the branches from that pursued in the stem. When it follows the same course in the stem and branches, they are *homodromous;* when the direction differs, they are *heterodromous.* In different species of the same genus the phyllotaxis frequently varies.

All modifications of leaves follow the same laws of arrangement as true leaves—a fact which is of importance in a morphological point of view. In Dicotyledonous plants the first leaves produced (the cotyledons) are opposite, in some cases verticillate. This arrangement often continues during the life of the plant, but at other times it changes, passing into distichous and spiral forms. Some tribes of plants are distinguished by their opposite or verticillate, others by their alternate, leaves. Labiate plants have decussate leaves, while Boraginaceæ have alternate leaves, and Tiliaceæ usually have distichous leaves; Cinchonaceæ have opposite leaves; Galiaceæ, verticillate. Such arrangements as $\frac{2}{5}$, $\frac{3}{8}$, $\frac{5}{13}$, and $\frac{8}{21}$ are common in Dicotyledons. The first of these, called a *quincunx,* is met with in the Apple, Pear, and Cherry (fig. 130); the second, in the Bay, Holly, Plantago media; the third, in the cones of Pinus (Abies) alba (fig. 133); and the fourth in those of the Pinus (Abies) Picea. In Monocotyledonous plants there is only one seed-leaf or cotyledon produced, and hence the arrangement is at first alternate; and it generally continues so more or less, rarely being verticillate. Such arrangements as $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{2}{5}$ are common in Monocotyledons, as in Grasses, Sedges, and Lilies. In Acotyledons the leaves assume all kinds of arrangement, being opposite, alternate, and verticillate. It has been found in general that, while the number 5 occurs in the phyllotaxis of Dicotyledons, 3 is common in that of Monocotyledons.

In the axil of previously formed leaves leaf-buds arise. These *leaf-buds* contain the rudiments of a *shoot,* and consist of leaves covering a growing point. The buds of trees of temperate climates, which lie dormant during the winter, are protected by cataphyllary leaves constituting the *tegmenta* or *perulæ.* These scales or protective appendages of the bud consist either of the altered laminæ, or of the enlarged petiolary sheath, or of stipules, as in the Fig and Magnolia, or of one or two of these parts combined. These are often of a coarse nature, serving a temporary purpose, and then falling off when the leaf is expanded. They are frequently covered with a resinous matter, as in Balsam-poplar and Horse-chestnut, or by a thick downy covering as in the Willow. In plants of warm climates the buds have often no protective appendages, and are then said to be *naked.*

Vernation.

The arrangement of the leaves in the bud has been denominated *vernation, præfoliation,* and *gemmation.* In considering vernation we must take into account both the manner in which each individual leaf is folded and also the arrangement of the leaves in relation to each other. These vary in different plants, but in each species they follow a regular law. The leaves in the bud are either placed simply in apposition, as in the Mistleto, or they are folded or rolled up longitudinally or laterally, giving rise to different kinds of vernation, as delineated in figs. 135 to 144, where the folded or curved lines represent the leaves, the thickened part being the midrib. The leaf taken individually is either folded longitudinally from apex to base, as in the Tulip-tree, and called *reclinate* or *replicate;* or rolled up in a circular manner from apex to base, as in Ferns (fig. 135), and called *circinate;* or folded laterally, *conduplicate* (fig. 136), as in Oak; or it has several folds like a fan, *plicate* or *plaited* (fig. 137), as in Vine and Sycamore, and in leaves with radiating vernation, where the ribs mark the foldings; or it is rolled upon itself, *convolute* (fig. 138), as in Banana and Apricot; or its edges are rolled inwards, *involute* (fig. 139), as in Violet; or outwards, *revolute* (fig. 140), as in Rosemary. The different divisions of a cut

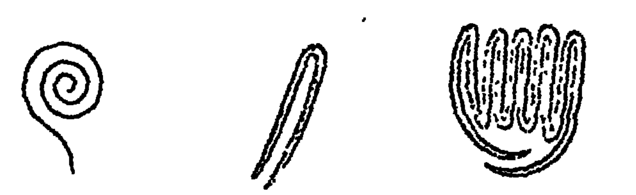

Fig. 135. Fig. 136. Fig. 137.

Fig. 140.—Transverse section of a revolute leaf.

leaf may be folded or rolled up separately, as in Ferns, while the entire leaf may have either the same or a different kind of vernation. The leaves have a definite relation to each other in the bud, being either opposite, alternate, or verticillate; and thus different kinds of vernation are produced. Sometimes they are nearly in a circle at the same level, remaining flat, or only slightly convex externally, and placed so as to touch each other by their edges, thus giving rise to *valvate* vernation. At other times they are at different levels, and are applied over each other, so as to be *imbricated,* as in Lilac, and in the outer scales of Sycamore (fig. 63); and occasionally the margin of one leaf overlaps that of another, while it in its turn is overlapped by a third, so as to be *twisted, spiral,* or *contortive.* When leaves are applied to each other face to face, without being folded or rolled together, they are *appressed.* When the leaves are more completely folded they either touch at their extremities and are *accumbent* or *opposite* (fig. 141), or are folded inwards by their margin, and become *induplicate;* or a conduplicate leaf covers another similarly folded, which in turn covers a third, and thus the vernation is *equitant* (fig. 142), as in Privet; or conduplicate leaves are placed so that the half of the one covers the half

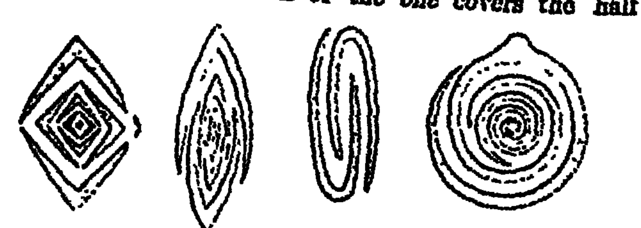

Fig. 141. Fig. 142. Fig. 143. Fig. 144.

Fig. 143.—Transverse section of a bud, showing two leaves folded in an obvolute manner. Each is conduplicate, and one embraces the edge of the other.
Fig. 144.—Transverse section of a bud, showing two leaves arranged in a supervolute manner.

of another, and thus they become *half-equitant* or *obvolute* (fig. 143), as in Sage. When in the case of convolute leaves one leaf is rolled up within the other, it is *supervolute* (fig. 144). The scales of a bud sometimes exhibit one kind of vernation, and the leaves another. The same modes of arrangement occur in the flower-buds, as will be afterwards shown.

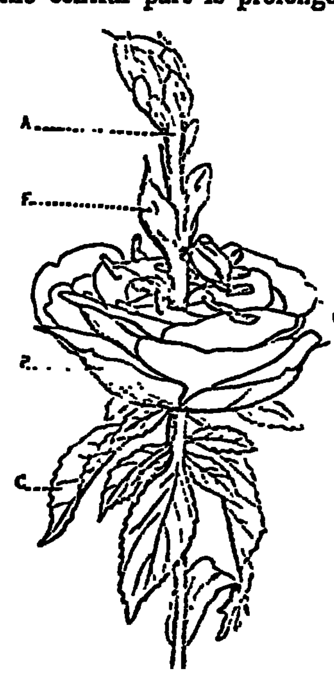
Leaves expose the fluids of plants to the influence of air

and light. The fluids so exposed are elaborated. and thus fitted for the formation of the various vegetable tissues and secretions. For the proper performance of this function the structure of the leaves, and their arrangement on the stem and branches, render them well adapted. The cells in the lower side of a leaf where stomata exist are chiefly concerned in the aeration of the sap, whilst other assimilative processes go on in the upper cells. The elaboration of fluids in the leaves necessarily implies interchange of their constituents with those of the surrounding atmosphere; hence two processes are inevitable—a passing inwards into the leaf of the atmospheric elements by a *process of absorption*, and an outward current of the components of the plant-juices by a *process of exhalation.* The absorption of carbonic acid, water, and other fluids is carried on by the leaves, chiefly through their stomata, and most rapidly by the under surface of ordinary leaves in which the cuticle is thinnest, the cellular tissue least condensed, and stomata most abundant; the upper surface of the leaf, which usually presents a polished and dense epidermis with few stomata, taking little part in such a process. An exhalation of both liquids and gases also takes place from the leaves, regulated by the number and the size of stomata as well as by the nature of the epidermis. The process of *transpiration* of fluids imparts moisture to the atmosphere, and hence the difference between the air of a wooded country and that of a country deprived of forests. Thus leaves have an important influence upon the climate of a country. In darkness little or no transpiration takes place, and in diffuse daylight it is less than in the sun's rays. The exhalation of gases constitutes the process of *respiration.* The nature and amount of the gases respired depends both on the circumstances in which the leaves are placed and on the condition of the plant. But normally at all times there seems to be a respiration of carbonic acid, which, under the influence of light, is at once decomposed by the green parts of the plant, the carbon being fixed and the oxygen set free; consequently, in darkness no oxygen is eliminated. Leaves, after performing their functions for a certain time, wither and die. In doing so they frequently change colour, and hence arise the beautiful and varied tints of the autumnal foliage. This change of colour is chiefly occasioned by the diminished circulation in the leaves, and the higher degree of oxidation to which their chlorophyll has been submitted.

Leaves which are articulated with the stem, as in the Walnut and Horse-chestnut, fall and leave a scar, while those which are continuous with it remain attached for some time after they have lost their vitality, as in the Beech. Most of the trees of Great Britain have deciduous leaves, their duration not extending over more than a few months, while in trees of warm climates the leaves often remain for two or more years. In tropical countries, however, many trees lose their leaves in the dry season. The period of defoliation varies in different countries according to the nature of their climate. Trees which are called evergreen, as Pines and Evergreen-oak, are always deprived of a certain number of leaves at intervals, sufficient being left, however, to preserve their green appearance. The cause of the fall of the leaf in cold climates seems to be deficiency of light and heat in winter, which causes a cessation in the functions of the cells of the leaf; its fluids disappear by evaporation; its cells and vessels become contracted and diminished in their calibre; various inorganic matters accumulate in the textures; the whole leaf becomes dry; its parts lose their adherence; a process of disjunction takes place by a folding inwards of the tissue at the point where the leaf joins the stem or branch which gradually extends until complete separation takes place, and the leaf either falls by its own weight or is detached by the wind. In warm climates the dry season gives rise to similar phenomena.

II. ORGANS OF REPRODUCTION.

We now proceed to pass in review the reproductive organs of plants. In Phanerogamous plants, as already mentioned, these organs are conspicuous, and constitute what is known as the flower; in Cryptogamous plants they are inconspicuous. All Dicotyledonous and Monocotyledonous plants are included in the former; Acotyledonous and Thallogenous plants compose the latter. The structures which go to form these organs are not, however, formations of a new type, but are merely modifications of those structures which we have already considered under the nutritive organs. For example, the various parts of the flower in Phanerogams are really phyllomes, the supporting structures of the flower are caulomes, the spore-bearing sac of many Cryptogams is a trichome; and in this way a morphological equivalency may be traced betwixt the two series of organs. Further, the difference betwixt the reproductive organs of Phanerogams and those of Cryptogams is one more of degree of differentiation than of actual morphological difference. In Phanerogams the flowers or floral axes are produced from flower-buds, just as leaf-shoots arise from leaf-buds. These two kinds of buds have a resemblance to each other as regards the arrangement and the development of their parts; and it sometimes happens, from injury and other causes, that the part of the axis which, in ordinary cases, would produce a leaf-bud, gives origin to a flower-bud. A flower-bud has not in ordinary circumstances any power of extension by the development of its central cellular portion. In this respect it differs from a leaf-bud. In some cases, however, of monstrosity, especially seen in the Rose (fig. 145) and Geum, the central part is prolonged, and bears leaves or flowers. In such cases the flowers, so far as their functional capabilities are concerned, are usually abortive.



Flower-buds, like leaf-buds, are produced in the axil of leaves, which are called *floral* leaves, *bracts*, or *hypsophyllary* leaves.

The term *bract* is properly applied to the leaf from which the primary floral axis, whether simple or branched, arises, while the leaves which arise on the axis between the bract and the outer envelope of the flower are *bracteoles* or *bractlets.* Bracts sometimes do not differ from the ordinary leaves, and are then called *leafy*, as in Veronica hederifolia, Vinca, Anagallis, and Ajuga. Like leaves they are entire or divided. In general as regards their form and appearance, they differ from ordinary leaves, the difference being greater in the upper than in the lowe[r] They are distinguished by th[e] flower or flower-stalk. The[i] of the leaf. When the flowe[r]

applied closely to the calyx, and may thus be confounded with it, as in Malvaceæ and species of Dianthus and Eranthis, where they have received the name of *epicalyx* or *calyculus*. In some Rosaceous plants an epicalyx is present, due to the formation of stipulary structures by the sepals. In many cases bracts seem to perform the function of protective organs, within or beneath which the young flowers are concealed in their earliest stage of growth.

When bracts become coloured, as in Amherstia nobilis, Euphorbia splendens, Erica elegans, and Salvia splendens, they may be mistaken for parts of the corolla. They are sometimes mere scales or threads, and at other times they are abortive, and remain undeveloped, giving rise to the *ebracteated* inflorescence of Cruciferæ and some Boraginaceæ. Sometimes no flower-buds are produced in their axil, and then they are *empty*. A series of empty coloured bracts terminates the inflorescence of Salvia Horminum. The smaller bracts or bracteoles, which occur among the subdivisions of a branching inflorescence, often produce no flower-buds, and thus anomalies occur in the floral arrangements. Bracts are occasionally persistent, remaining long attached to the base of the peduncles, but more usually they are deciduous, falling off early by an articulation. In some instances they form part of the fruit, becoming incorporated with other organs. Thus, the cones of Firs and the strobili of the Hop are composed of a series of bracts arranged in a spiral manner, and covering fertile flowers; and the scales on the fruit of the Pine-apple are of the same nature. In amenta or catkins the bracts are called *squamæ* or scales. At the base of the general umbel in Umbelliferous plants, a whorl of bracts often exists, called a *general involucre*, and at the base of the smaller umbels or umbellules there is a similar leafy whorl called *involucel* or *partial involucre*. In some instances, as in Fool's-parsley, there is no general involucre, but simply an involucel; while, in other cases, as in Fennel, neither involucre nor involucel is developed. In Compositæ the name involucre is applied to the leaves, scales, or *phyllaries*, surrounding the head of flowers (fig. 146, *i*), as in Dandelion, Daisy, Artichoke. This involucre is frequently composed of several rows of leaflets, which are either of the same or of different forms and lengths, and often lie over

Plate VII.

FIG. 146.—Head (capitulum) of Marigold (*Calendula*), showing a congeries of flowers, enclosed by *rows* of bracts or phyllaries, *i*, at the base, which are collectively called an involucre.
FIG. 147.—Fruit of the Oak (*Quercus pedunculata*), showing a collection of bracts, *a*, forming the cup (cupula) of the acorn *b*.

each other in an imbricated manner. When the bracts are arranged in two rows, and the outer row is perceptibly smaller than the inner, the involucre is sometimes said to be *caliculate*, as in Senecio. The leaves of the involucre are spiny in Thistles and in Dipsacus, and hooked in Burdock. Such whorled or verticillate bracts may either remain separate (*polyphyllous*), or may be united by cohesion (*gamophyllous*), as in many species of Bupleurum, and in Lavatera. In Compositæ besides the general envelope called the involucre, there are frequently *chaffy* and *setose* bracts at the base of each flower, and in Dipsacaceæ a membranous tube surrounds each flower. These structures are of the nature of an epicalyx. In the acorn the *cupula* or cup (fig. 147, *a*) is formed by a growing upwards of the flower-stalk immediately beneath the flower, upon which scaly or spiny protuberances appear. It is of the nature of bracts. Bracts also compose the husky covering of the Hazel-nut. In the Yew the succulent covering of the seed is by some considered to be formed by the bracts.

When bracts become united together, and overlie each other in several rows, it often happens that the outer ones do not produce flowers, that is, are empty or sterile. In the Artichoke the outer imbricated scales or bracts are in this condition, and it is from the membranous white scales or bracts (*paleæ*) forming the choke attached to the edible receptacle that the flowers are produced. The sterile bracts of the Daisy occasionally produce *capitula*, and give rise to the Hen-and-Chickens Daisy. In place of developing flower-buds, bracts may, in certain circumstances, as in *proliferous* or *viviparous* plants, produce leaf-buds, and the flower-buds, like the leaf-buds, may be *terminal* or they may be *lateral*.

A sheathing bract enclosing one or several flowers is called a *spatha* or *spathe*. It is common among Monocotyledons, as Narcissus (figure 148), Snow-flake, Arum, and Palms. In some Palms it is 20 feet long, and encloses 200,000 flowers. It is often associated with that form of inflorescence termed the *spadix*, and may be coloured, as in Richardia æthiopica, sometimes called the Æthiopian- or Trumpet Lily. When the spadix is compound or branching, as in Palms, there are smaller spathes, surrounding separate parts of the inflorescence, to which the name *spathellæ* has sometimes been given. The spathe protects the flowers in their young state, and often falls off after they are developed, or hangs down in a withered form, as in some Palms, Typha, and Pothos. In Grasses the outer scales of the spikelets have been considered as sterile bracts, and have received the name of *glumes* (fig. 149, *gl*), and in Cyperaceæ bracts enclose the organs of reproduction. Bracts are frequently changed into complete leaves. This change is called phyllody of bracts. It is seen in species of Plantago, especially in the variety of Plantago media, called the Rose-plantain in gardens. In this plant the bracts become leafy, and form a rosette round the flowering axis. Similar changes occur in Plantago major, P. lanceolata, Ajuga reptans, the Dandelion, the Daisy, the Dahlia, and in Umbelliferous plants. The conversion of bracts into stamens has been observed in the case of Abies excelsa. This has been called staminody of bracts. A lengthening of the axis of the female strobilus of Coniferæ is not of infrequent occurrence in Cryptomeria japonica, Larix europæa, &c., and this is usually associated with a leaf-like condition of the bracts, and sometimes even with the development of leaf-bearing shoots in place of the scales.

Plate XVI

Fig. 148.

Flowers of Polyanthus Narcissus (*Narcissus Tazetta*) bursting from a sheathing bract *b*.

The arrangement of the flowers on the axis, or the ramification of the floral axis, is called *inflorescence* or *anthotaxis*. The primary axis of inflorescence is sometimes called *rachis;* its branches, whether terminal or lateral, which form the stalks supporting flowers or clusters of flowers, are *peduncles*, and if small branches are given off by it, they are called *pedicels*. A flower having a stalk is called *pedunculate* or *pedicellate;* one having no stalk is *sessile*. In describing a branching inflorescence, it is common to speak of the rachis as the *primary* floral axis, its branches as the *secondary* floral axes, their divisions as the *tertiary* floral axes, and so on; thus avoiding any confusion that might arise from the use of the terms *rachis*, *peduncle*, and *pedicel*.

uncle. The *peduncle* may be cylindrical, compressed, or grooved; simple, bearing a single flower, as in Primrose; or branched, as in London-pride. It is sometimes succulent, as in the te IV. Cashew, in which it forms the large coloured expansion supporting the nut; spiral, as in Cyclamen and Vallisneria; or spiny, as in Alyssum spinosum. In some Rushes there is a green terete, and sometimes spiral, floral axis. Sometimes the peduncle proceeds from radical leaves, that is, from an axis which is so shortened as to bring the leaves close together in the form of a cluster, as in the Primrose, Auricula, Hyacinth, &c. In such cases it is termed a *scape*. The floral axis may be shortened, assuming a flattened, convex, or concave form, and bearing numerous flowers, as in the Artichoke, Daisy, and Fig (fig. 150). In these cases it is called a *receptacle* or *phoranthium* or *clinanthium*. The floral axis sometimes assumes a leaf-like or *phylloid* appearance, bearing numerous flowers at its margin, as in Xylophylla longifolia and in Ruscus; or it appears as if formed by several peduncles united together, constituting a fasciated axis, as in the Cockscomb, in which the flowers form a peculiar crest at the apex of the flattened peduncles. Adhesions occasionally take place between the peduncle and the bracts or leaves of the plant, as in the Lime-tree (fig. 151), Helwingia, Chailletia, several species of Hibiscus, and Zostera. The adhesion of the peduncles to the stem accounts for the extra-axillary position of flowers, as in many Solanaceæ. When this union extends for a considerable length along the stem, several leaves may be interposed between the part where the peduncle becomes free and the leaf whence it originated, and it may be difficult to trace the connection. The peduncle occasionally becomes abortive, and in place of bearing a flower, is transformed into a tendril; at other times it is hollowed at the apex, so as apparently to form the lower part of the outer whorl of floral leaves as in Eschscholtzia. The termination of the Plate II.

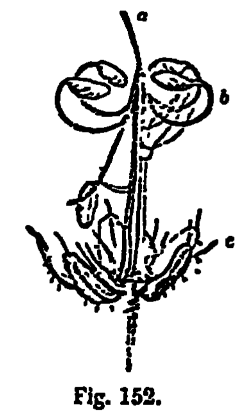

Fig. 152.

FIG. 151.—Leaf and flowering branch of the Lime-tree (*Tilia*). The bract *b* is adherent to the peduncle or flower-stalk. The flowers are arranged in a corymbose cyme.
FIG. 152.—The calyx and beak-like process of Geranium, with the parts of the pistil (the carpels) curled upwards, so as to scatter the seed. *a*, the extremity of the rostrum or beak, whence the name crane's bill is derived; *b*, the carpels curled up by means of the styles which are attached to the beak; *c*, the calyx.

peduncle, or the part on which the whorls of the flower are arranged, is called the *thalamus* or *torus*. The term *receptacle* is also sometimes applied to this, whether expanded and bearing several flowers, or narrowed so as to bear one. It may be considered as the growing point of the axis, which usually is arrested by the production of the flowers, but which sometimes becomes enlarged and expanded. Thus, in the Geranium (fig. 152) it is prolonged beyond the flower in the form of a beak (*rostrate*); in the Arum (fig. 153) it is a club-shaped fleshy column; in the Strawberry (fig. 154) it becomes a conical succulent mass, on which the seed-vessels are placed; while in Nelumbium it forms a truncated tabular top-like expansion (*turbinate*), enveloping the seed-vessels. The margins of the receptacle may grow up whilst the centre remains depressed, and thus a concave torus is formed, as in the Rose (fig. 155). In some monstrous flowers of the Rose and Geum it is prolonged as a branch bearing leaves. Peduncles and pedicels sometimes become remarkably elongated, and this elongation of the flower-stalks sometimes alters the general character of the inflorescence. We occasionally observe the heads of flowers of the common White Clover becoming racemose by the lengthening of the flower-stalks.

Inflorescence.

Before proceeding to an examination of the parts of the flower-bud, we will consider the various modes of arrangement of the flowers upon the axis, or the *inflorescence*.

We may recognize two distinct types of inflorescence—one in which the flowers always arise as lateral shoots from a primary axis, which goes on elongating, and the lateral shoots never exceed in their development the length of the primary axis beyond their point of origin. The flowers are thus always *axillary*. Exceptions, such as in Cruciferous plants, are due to the non-appearance of the bracts. In the other type the primary axis terminates in a single flower, but lateral axes are given off from the axil of bracts, which again repeat the primary axis, and the development of each lateral axis is stronger than the primary axis beyond its point of origin. The flowers produced in this inflorescence are thus *terminal*. The first kind of inflorescence is *indeterminate*, *indefinite*, or *axillary*. Here the axis is either elongated, producing flower-buds as it grows, the lower expanding first; or it is shortened and depressed, and the outer flowers expand first. The expansion of the flowers is thus *centripetal*, that is, from base to apex, or from circumference to centre. This kind of inflorescence is shown in fig. 156, where the leaf from which the cluster of flowers is produced, *f*, represents the bract or floral leaf. The *rachis*, or primary axis of the flower is *a′*; this produces small leaflets *b*, which bear smaller flower-leaves or bractlets, from which peduncles or secondary axes spring, each bearing single flowers. In fig. 157 the same kind of inflorescence is shown on a shortened axis, the outer flowers expanding first, and those in the centre last.

Fig. 156.

Fig. 157.

Fig. 156.—Raceme of Barberry (*Berberis vulgaris*) produced in the axil of a leaf or bract *f*, which has been transformed into a spine, with two stipules *s* at its base; *a′*, primary floral axis, bearing small alternate bracts *b*, in the axil of which the secondary axes *a″*, *a″* are produced, each terminated by a flower. The expansion of the flowers is centripetal, or from base to apex: the lower flowers have passed into the state of fruit, the middle are fully expanded, and those at the top are still in bud. Indeterminate simple inflorescence.
Fig. 157.—Head of flowers (capitulum) of Scabiosa atro-purpurea. The inflorescence is simple and indeterminate, and the expansion of the flowers centripetal, those at the circumference opening first.

flower *f‴*. From this tertiary axis a fourth is in progress of formation. Here *f′* is the termination of the primary axis, and this flower expands first, while the other flowers are developed centrifugally on separate axes.

A third series of inflorescences, termed *mixed*, may be recognized. In them the primary axis has an arrangement belonging to the opposite type from that on the branches, or *vice versa*. According to the mode and degree of development of the lateral shoots and also of the bracts, various forms of both inflorescences result.

Amongst indefinite forms the simplest occurs when a lateral shoot produced in the axil of a large single foliage leaf of the plant ends in a single flower, the axis of the plant elongating beyond, as in Veronica hederifolia, Vinca minor, and Lysimachia nemorum. The flower in this case is *solitary*, and the Inflorescence has been designated *solitary axillary*. The ordinary leaves in this case become floral leaves or bracts, by producing flower-buds in place of leaf-buds. The flowers, being all offshoots of the same axis, are said to be of the same generation or degree, and their number, like that of the leaves of this main axis, is indefinite, varying with the vigour of the plant. Usually, however, the floral axis, arising from a more or less altered leaf or bract, instead of ending in a solitary flower, is prolonged, and bears numerous leaflets, called *bracteoles* or *bractlets*, from which smaller peduncles are produced, and those again in their turn may be branched in a similar way. Thus the flowers are arranged in groups, and frequently very complicated forms of inflorescence result. When the primary peduncle or floral axis, as in fig. 156, *a′*, is elongated, and gives off pedicels *a″*, of nearly equal length ending in single flowers, a *raceme* or *cluster* is produced, as in Currant, Hyacinth, and Barberry. If the secondary floral axes give rise to tertiary ones, the raceme is branching, and forms what is by some called a *panicle*, as in Yucca gloriosa; but it is better to restrict this term to the lax inflorescence of some Grasses and Rushes. If in a raceme the lower flower-stalks are developed more strongly than the upper, and thus all the flowers are nearly on a level, a *corymb* is formed, which may be simple, as in fig. 159, where the primary axis *a′* divides into secondary axes *a″*, *a″*, which end in single flowers; or branching, where the secondary axes again subdivide. If the peduncles or secondary axes are very short or awanting, so that the flowers are sessile, a *spike* is produced, as in Plantago and Verbena officinalis (fig. 160). The spike sometimes bears unisexual flowers, usually staminiferous, the whole falling off by an articulation, as in Willow or Hazel (fig. 161), and then it is called an *amentum* or *catkin*, hence such trees are called *amentiferous*; at other times it becomes succulent, bearing numerous flowers, surrounded by a sheathing bract or spathe, and then it constitutes a *spadix*, which may be simple, as in Arum maculatum (fig. 153), or branching, as in Palms. Plate XVI.
A spike bearing female flowers only, and covered with scales, is either a *strobilus*, as in the Hop; or a *cone*, as in the Fir (fig. 133). It may be mentioned here that many do not consider the cone of Firs an axis of inflorescence,

Fig. 158.

Plant of *Ranunculus bulbosus*, showing determinate inflorescence.

but regard it as a single flower with the floral leaves placed at different heights. In Grasses there are usually numerous sessile flowers arranged in small spikes, called *locustæ* or

Fig. 159.

Fig. 160.

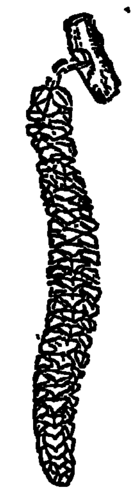

Fig. 161.

FIG. 159.—Corymb of *Cerasus Mahaleb*, produced in the axil of a leaf which has fallen, and terminating an abortive branch, at the base of which are modified leaves in the form of scales, *e*.

FIG. 160.—Spike of *Verbena officinalis*, showing sessile flowers on a common rachis. The flowers at the lower part of the spike have passed into fruit, those towards the middle are in full bloom, and those at the top are only in bud.

FIG. 161.—Amentum or catkin of Hazel (*Corylus Avellana*), consisting of an axis or rachis covered with bracts in the form of scales (*squamæ*), each of which covers a male flower, the stamens of which are seen projecting beyond the scale. The catkin falls off in a mass, separating from the branch by an articulation.

spikelets, which are either set closely along a central axis, or produced on secondary axes formed by the branching of the central one; to the latter form the term *panicle* is applied.

If the primary axis, in place of being elongated, is contracted, it gives rise to other forms of indefinite inflorescence. When the axis is so shortened that the secondary axes arise from a common point, and spread out as *radii* of nearly equal length, each ending in a single flower, or dividing again in a similar radiating manner, an *umbel* is produced, as in fig. 162. From the primary floral

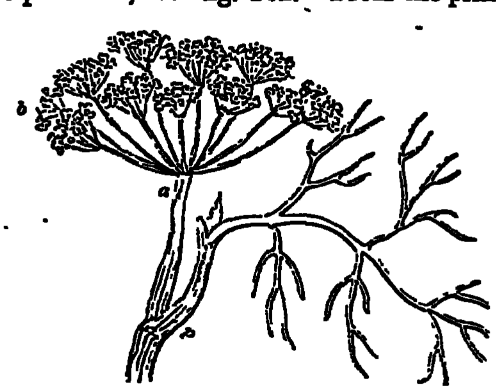

Fig. 162.

Compound umbel of Common Dill (*Anethum graveolens*), having a primary umbel *a*, and secondary umbels *b*, without either involucre or involucel. The petiole *p* of the leaf is sheathing, and has been denominated pericladium.

axis *a* the secondary axes come off in a radiating or umbrella-like manner, and end in small umbels *b*, which are called *partial umbels* or *umbellules*, to distinguish them from the *general umbel* formed by the branching of the primary axis. This inflorescence is seen in Hemlock, and other allied plants, which are hence called Umbelliferous. If there are numerous flowers on a flattened, convex, or slightly concave receptacle, having either very short pedicels or none, a *capitulum* (head), *anthodium*, or *calathium*, is formed, as in Dandelion, Daisy, and other Composite plants (fig. 146), also in Scabiosa (fig. 157) and Dipsacus. In the American Button-bush the heads are globular, in some species of Teazel, elliptical, while in Scabious, and in Composite plants, as Sunflower, Dandelion, Thistle, Centaury, and Marigold, they are somewhat hemispherical, with a flattened, slightly hollowed, or convex disk. If the margins of such a receptacle be developed upwards, the centre not developing, a concave receptacle is formed, which may partially or completely enclose a number of flowers that are generally unisexual. This gives rise to the peculiar inflorescence of Dorstenia (fig. 163), or to that of the Fig (fig. 150), where the flowers are placed on the inner surface of the hollow receptacle, and are provided with bracteoles. This inflorescence has been called *hypanthodium*.

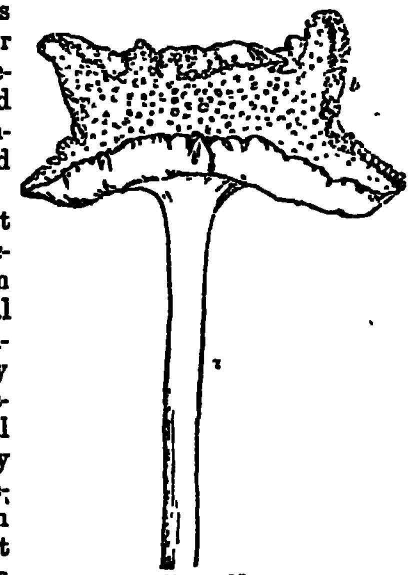

Fig. 163.

Peduncle *a* of *Dorstenia*, with concave receptacle *b*.

Lastly, we have what are called *compound indefinite* inflorescences. In these forms the lateral shoots, developed centripetally upon the primary axis, bear numerous bracteoles, from which floral shoots arise which may have a centripetal arrangement similar to that on the mother shoot, or it may be different. Thus we may have a group of racemes, arranged in a racemose manner on a common axis, forming a raceme of racemes or compound raceme, as in Astilbe. In the same way we may have compound umbels, as in Hemlock and most Umbelliferæ (fig. 162), a compound spike, as in Rye-grass, a compound spadix, as in some Palms, and a compound capitulum, as in the Hen-and-Chickens Daisy. Again, there may be a raceme of capitula, that is, a group of capitula disposed in a racemose manner, as in Petasites, a raceme of umbels, as in Ivy, and so on, all the forms of inflorescence being indefinite in disposition.

The elongation of secondary flower-stalks sometimes alters the general character of the inflorescence, changing a spike into a raceme, a raceme into a corymb, a capitulum into an umbel, and so forth. The capitulum of flowers in some Compositæ, such as Hypochæris radicata and Senecio vulgaris, by a similar change in the pedicels assumes the form of an umbel. Among Umbelliferæ the umbels are sometimes supported on very long stalks, while the pedicels of the individual flowers are not lengthened. In Eryngium the shortening of the pedicels changes an umbel into a capitulum. The umbellate inflorescence of Pelargonium has been seen changed into a raceme.

The simplest form of the definite type of inflorescence is seen in Anemone nemorosa and in Gentianella (Gentiana acaulis, fig. 164), where the axis terminates in a single flower, no other flowers being produced upon the plant. This is *solitary terminal* inflorescence. If other flowers were produced, they would arise as lateral shoots from the bracts below the first-formed flower. The general name of *cyme* is applied to the arrangement of a group of flowers in a definite inflorescence. A *cymose* inflorescence is an inflorescence where the primary floral axis before terminating in a flower gives off one or more lateral unifloral axes which repeat the process,—the development being only limited by the vigour of the plant. The floral axes are thus centrifugally developed. The cyme, according to its development, has been characterized as *biparous* or *uniparous*. In fig. 165 the biparous cyme is represented in the flowering branch of Erythræa Centaurium. Here the primary axis *a'* ends in a flower *f*, which has passed

Definite inflorescence

into the state of fruit. At its base two leaves are produced, each of which is capable of developing buds. These are flower-buds, and constitute secondary axes a'' a'', ending in single flowers f'' f'', which are thus terminal and solitary; and at the base of these axes a pair of opposite leaves is

Fig. 164.
Gentianella (*Gentiana acaulis*). *a*, axis; *b*, flower; *c*, bract.

Fig. 165.
Flowering branch of *Erythræa Centaurium*.

produced, giving rise to tertiary axes a''' a''' a''', ending in single flowers f''' f''' f''', and so on. The term *dichotomous* has also been applied to this form of cyme. But these terms are not strictly correct, for here there is no dichotomous branching, although, when the terminal flower f of the generating axis has withered, an apparent dichotomy occurs; but the lateral axes on the several shoots are produced monopodially, and therefore the term is apt to lead to confusion regarding the development of the shoots. The name *dichasium* has, therefore, been substituted for the old term. In the natural order Caryophyllaceæ (Pink family) the dichasial cymose form of inflorescence is very general. In some members of the tribe, as Dianthus barbatus, D. Carthusianorum, &c., in which the peduncles are short, and the flowers closely approximated, with a centrifugal expansion, the inflorescence has the form of a contracted dichasium, and receives the name of *fascicle* (fig. 166). A

Fig. 166.
Fascicle of Mallow (*Malva sylvestris*).

similar inflorescence is seen in Xylophylla longifolia. When the axes become very much shortened, the arrangement is more complicated in appearance, and the nature of the inflorescence can only be recognized by the order of opening of the flowers. In Labiate plants, as the Dead-nettle (Lamium), the flowers are produced in the axil of each of the foliage leaves of the plant, and they appear as if arranged in a simple whorl of flowers. But on examination it is found that there is a central flower expanding first, and from its axis two secondary axes spring bearing solitary flowers; the expansion is thus centrifugal. The inflorescence is therefore a contracted dichasium, the flowers being sessile, or nearly so, and the clusters are called *verticillasters* (fig. 167).

Fig. 167.
Flowering stalk of the White Dead-nettle, (*Lamium album*). The bracts *b*, *b* are like the ordinary leaves of the plant, and produce clusters of flowers in their axil. The clusters are called verticillasters, and consist of flowers which are produced in a centrifugal manner.

Sometimes, especially towards the summit of a dichasium, owing to the exhaustion of the growing power of the plant, only one of the bracts gives origin to a new axis, the other remaining empty; thus the inflorescence becomes unilateral, and further development is arrested. In addition to the dichasial form there are others where more than two lateral axes are produced from the primary floral axis, each of which in turn produces numerous axes. To this form the terms *trichotomous* and *polytomous cyme* have been applied; but these are now usually designated *cymose umbels*. They are well seen in some species of Euphorbia. Another term, *anthela*, has been used to distinguish such forms as occur in several species of Luzula and Juncus, where numerous lateral axes arising from the primary axis grow very strongly, and develop in an irregular manner.

In the uniparous cyme a number of floral axes are successively developed one from the other, but the axis of each successive generation, instead of producing a pair of bracts, produces only a single one. The basal portion of the consecutive axes may become much thickened and arranged more or less in a straight line, and thus collectively form an apparent or false axis or *sympodium*, and the inflorescence thus simulates a raceme. In the true raceme, however, we find only a single axis, producing in succession a series of bracts, from which the floral peduncles arise as lateral shoots, and thus each flower is on the same side of the floral axis as the bract in the axil of which it is developed; but in the uniparous cyme the flower of each of these axes, the basal portions of which unite to form the false axis, is situated on the opposite side of the axis to the bract from which it apparently arises (fig. 168). This bract is not, however, the one from which the axis terminating in the flower arises, but is a bract produced upon it, and gives origin in its axil to a new axis, the basal portion of which, constituting the next part of the false axis, occupies the angle between this bract and its parent axis, —the bract from which the axis really does arise being situated lower down upon the same side of the axis with itself. The uniparous cyme presents two forms, the *scorpioid* or *cicinal* and the *helicoid* or *bostrychoid*.

In the scorpioid cyme the flowers are arranged alternately in a double row along one side of the false axis (fig. 169) the bracts when developed forming a second double

row on the opposite side, as seen in the Henbane; the whole inflorescence usually curves on itself like a scorpion's tail, hence its name. In fig. 170 is shown a diagrammatic sketch of this arrangement. The false axis, *a b c d*, is formed by

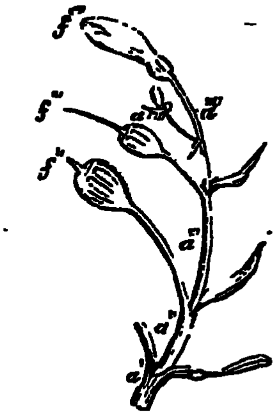

Fig. 168.

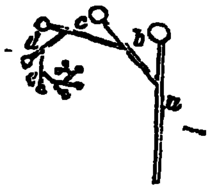

Fig. 170.

Fig. 169.

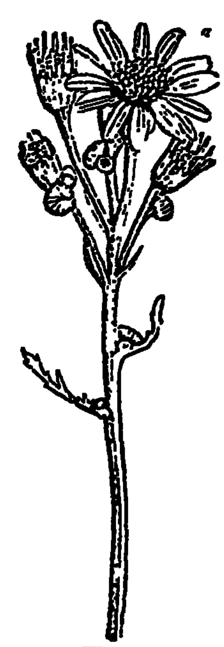

Fig. 171.

FIG. 168.—False raceme or helicoid cyme of a species of Alströmeria. $a' a'' a''' a''''$ are separate axes successively developed, which appear to form a simple continuous raceme, of which the axes form the internodes. It is a definite uniparous inflorescence, however, with centrifugal evolution. Each of the axes is produced in the axil of a leaf, and is terminated by a flower $f' f'' f''' f''''$, opposite to that leaf, and the axes have a spiral arrangement.
FIG. 169.—Scorpioidal or cicinal cyme of Forget-me-not (*Myosotis palustris*).
FIG. 170.—Diagram of definite floral axes *a, b, c, d, e*.
FIG. 171.—Flowering stalk of a kind of Ragwort (*Senecio*). The flowers are in heads (capitula), and open from the circumference inwards in an indefinite centripetal manner. The heads of flowers, on the other hand, taken collectively, expand centrifugally—the central one *a* first. Each head of flowers terminates a separate axis. They form together a corymb of capitula. The inflorescence is called mixed.

successive generations of unifloral axes, the flowers being arranged along one side alternately and in a double row; had the bracts been developed they would have formed a similar double row on the opposite side of the false axis; the whole inflorescence is represented as curved on itself. In fig. 169 the same scorpioid form of uniparous cyme is seen in the Forget-me-not, with the double row of flowers on one side of the false axis, but in this case the bracts, which should appear on the opposite side, are not developed, and hence the cyme is not complete. The inflorescences in the family Boraginaceæ are usually regarded as true scorpioid cymes. But it has been recently shown that in Myosotis (Forget-me-not) the axis is not a sympodium, but the branching takes place monopodially, therefore it should more correctly be regarded as a raceme with flowers only on one side and curving on itself. In Hyoscyamus (Henbane) and other Atropaceæ the branching is dichotomous, so that the inflorescence in this case also ought not to be regarded as a scorpioid cyme.

In the helicoid cyme there is also a false axis formed by the basal portion of the separate axes, but the flowers are not placed in a double row, but in a single row, and form a spiral or helix round the false axis. In Alströmeria, as represented in fig. 168 the axis a' ends in a flower (cut off in the figure) and bears a leaf. From the axil of this leaf, that is, between it and the primary axis a' arises a secondary axis a'', ending in a flower f'', and producing a leaf about the middle. From the axil of this leaf a tertiary floral axis a''', ending in a flower f''', takes origin. In this case the axes are not arranged in two rows along one side of the false axis, but are placed at regular intervals, so as to form an elongated spiral round it.

Compound definite inflorescences are by no means common, but in Streptocarpus polyanthus, and in several Calceolarias, we probably have examples. Here there are *scorpioid cymes of pairs of flowers*, each pair consisting of an older and a younger flower.

Forms of inflorescence occur, in which both the definite and indefinite types are represented; these, then, are *mixed* inflorescences. Thus in Composite plants, such as Hawk-weeds (Hieracia) and Ragworts (Senecio, fig. 171), the *heads* of flowers, taken as a whole, are developed centrifugally, the terminal head first, while the *florets*, or small flowers on the receptacle, open centripetally, those at the circumference first. So also in Labiatæ, such as Dead-nettle (Lamium), the different whorls of inflorescence are developed centripetally, while the florets of the verticillaster are centrifugal. This mixed character presents difficulties in such cases as Labiatæ, where the leaves, in place of retaining their ordinary form, become bracts, and thus might lead to the supposition of the whole series of flowers being one inflorescence. In such cases the cymes are described as spiked, racemose, or panicled, according to circumstances. In Saxifraga umbrosa (London-pride) and in the Horse-chestnut we meet with a raceme of scorpioid cymes; in Sea-pink, a capitulum of contracted scorpioid cymes (often called a glomerulus); in Laurustinus, a compound umbel of dichasial cymes; a scorpioid cyme of capitula in Vernonia centriflora. In the catkins of the Birch we have, in reality, spikes of contracted dichasial cymes. In the Bell-flower (Campanula), there is a racemose uniparous cyme. In the Privet (Ligustrum vulgare) there are numerous racemes of dichasia arranged in a racemose manner along an axis; the whole inflorescence thus has an appearance not unlike a bunch of grapes, and has been called a *thyrsus*.

Mixed inflorescence

TABULAR VIEW OF INFLORESCENCE.

A. Indefinite Centripetal Inflorescence.
- I. Flowers solitary, axillary. *Vinca, Veronica hederifolia.*
- II. Flowers in groups, pedicellate.
  - 1. Elongated form (Raceme), *Hyacinth, Laburnum, Currant.* (Corymb), *Ornithogalum.*
  - 2. Contracted or shortened form (Umbel), *Cowslip, Astrantia*
- III. Flowers in groups, sessile.
  - 1. Elongated form (Spike), *Plantago.* (Spikelet), *Grasses.* (Amentum, Catkin), *Willow, Hazel.* (Spadix) *Arum*, some *Palms.* (Cone), *Fir, Spruce.* (Strobilus), *Hop.*
  - 2. Contracted or shortened form (Capitulum), *Daisy, Dandelion, Scabious.*
- IV. Compound Indefinite Inflorescence.
  - *a.* Compound Spike, *Rye-grass.*
  - *b.* Compound Spadix, *Palms.*
  - *c.* Compound Raceme, *Astilbe.*
  - *d.* Compound Umbel, *Hemlock* and most *Umbelliferæ.*
  - *e.* Raceme of Capitula, *Petasites.*
  - *f.* Raceme of Umbels, *Ivy.*

B. Definite Centrifugal Inflorescence.
- I. Flowers solitary, terminal. *Gentianella, Peony.*
- II. Flowers in Cymes.
  - 1. Uniparous Cyme.
    - *a.* Helicoid Cyme (axes forming a spiral).
      - * Elongated form. *Alströmeria.*
      - ** Contracted form, [illegible]
    - *b.* Scorpioid Cyme (axes unilateral, two rows).
      - * Elongated form, *Forget-me-not, Symphytum, Henbane.*
      - ** Contracted form, *Erodium, Alchemilla arvensis.*

2. Biparous Cyme (Dichotomous), including 3-5-chotomous Cymes (Dichasium, Cymose Umbel, Anthela).
   a. Elongated form, *Cerastium*, *Stellaria*.
   b. Contracted form (Verticillaster), *Dead-nettle*, *Pelargonium*.
3. Compound Definite Inflorescence. *Streptocarpus polyanthus*, many *Calceolarias*.

C. Mixed Inflorescence.
1. Raceme of Scorpioid Cymes, *Horse-chestnut*.
2. Scorpioid Cyme of Capitula, *Vernonia centriflora*.
3. Compound Umbel of Dichotomous Cymes, *Laurustinus*.
4. Capitulum of contracted Scorpioid Cymes (Glomerulus), *Sea-pink*.

The flower. The flower is the *tout ensemble* of those organs which are concerned in reproduction. It is constituted by a portion of the floral axis bearing the sexual organs, usually with certain protective envelopes. The parts borne on the floral axis and composing the flower are all metamorphosed leaves, and, though usually very different in appearance from foliage leaves, their morphological resemblance is frequently shown by their developing as foliage leaves. The axis bearing the parts of the flower is usually very much contracted, no internodes being developed, and it frequently expands into a flattened or hollowed expansion termed the *thalamus* or *torus*; at other times, though rarely, the internodes are developed and it is elongated. Upon this torus the parts of the flower are arranged in a crowded manner, usually forming a series of verticils, the parts of which alternate; but they are sometimes arranged in a spiral manner, especially if the floral axis be elongated. In a typical flower, as in fig. 172, we recognize four distinct whorls of leaves:—an outer whorl of five parts, the *calyx*; within it, another whorl of five parts alternating with those of the outer whorl, the *corolla*; next comes a whorl of parts alternating with the parts of the corolla, the *andrœcium*; and in the centre is the *gynœcium*. Fig 173 is a diagrammatic representation of the arrangement of the parts of such a flower. The flower is supposed to be cut transversely, and the parts of each whorl are distinguished by a different symbol. Of these whorls the two internal, forming the male and female sexual organs, constitute the *essential* organs of reproduction; the two outer whorls are the protective coverings or *floral envelopes*. The calyx or outer covering (fig. 172, *c*) is formed of leaves, called *sepals*, which are generally of a greenish colour. The corolla *p*, the next covering, is composed of leaves, called *petals*, which are often showy, and normally alternate with the sepals. Sometimes, as in many Monocotyledons, the calyx and corolla *both* display rich colouring, and are apt to be confounded. In such cases the term *perianth*, or *perigone*, has been applied to avoid ambiguity. Thus, in the Tulip, Crocus, Lily, Hyacinth, authors speak of the parts of the perianth, in place of calyx and corolla, although in these plants an outer whorl (calyx) may be detected, of three parts, and an inner (corolla), of a similar number, alternating with them. When the parts of the calyx are in appearance like petals they are said to be *petaloid*, as in Liliaceæ. In some cases the petals have the appearance of sepals, then they are *sepaloid*, as in Juncaceæ. The term perianth is usually confined to the flowers of Monocotyledons, whatever colour they present, whether green, as in Asparagus, or coloured, as in Tulip. Some use the term perianth as a general one, and restrict the use of perigone to cases where a pistil only is present. In plants, as Nymphæa alba, where a spiral arrangement of the floral leaves occur, it is not easy to say where the calyx ends and the corolla begins, as these two whorls pass insensibly into each other. When both calyx and corolla are present, the plants are *dichlamydeous*; occasionally one becomes abortive, and then the flower is *monochlamydeous* (fig. 174), having a calyx only, or *apetalous*, having no petals. At times both are abortive, and then the flower is *achlamydeous*, or naked. It is important to remember that if only one perianth-whorl is present it is the calyx. The outermost whorl of the essential organs, collectively termed the *andrœcium*, is composed of a series of leaves

FIG. 172.—Flower of *Crassula rubens*. *c, c*, sepals; *p, p*, petals; *e, e*, stamens; *a, a*, carpels, each of them having a small scale-like appendage *a* at the base.

FIG. 173.—Diagram of a completely symmetrical flower, consisting of four whorls, each consisting of five parts. The outer row is the calyx formed of five sepals; the second is the corolla of five petals, alternating with the sepals; the third is the andrœcium, consisting of five stamens, alternating with the petals; the central whorl is the gynœcium, consisting of five carpels, alternating with the stamens.

FIG. 174.—Monochlamydeous (apetalous) flower of Goosefoot (*Chenopodium*), consisting of a single perianth (calyx) of five parts, enclosing five stamens, which are opposite the divisions of the perianth, owing to the absence of the petals.

FIG. 175.—Stamen, consisting of a filament (stalk) *f* and an anther *a*, containing powdery matter *p*, denominated pollen, which is discharged through slits in the two lobes of the anther.

FIG. 176.—The pistil of Tobacco (*Nicotiana Tabacum*), consisting of the ovary *o*, containing ovules, the style *s*, and the capitate stigma *g*. The pistil is placed on the receptacle *r*, at the extremity of the peduncle.

distinguished as the staminal leaves or *stamens*. These are the male sexual organs. In their most differentiated form each consists of a stalk, either filiform or foliaceous, the *filament* (fig. 175, *f*) supporting at its summit a lobed saccate mass, the *anther* (fig. 175, *a*), which contains a powdery matter, the *pollen* (fig. 175, *p*), which is discharged therefrom. In many cases, however, the staminal leaf resembles more nearly a cataphyllary leaf, bearing the pollen-sacs scattered over its surface, as in Cycadaceæ. The *gynœcium* or *pistil* is the central portion of the flower, and is the female sexual organ. It consists of one or more folded leaves, called *carpels*, either separate (fig. 172, *c*) or combined (fig. 174.) The parts distinguished in the pistil are the *ovary* (fig. 176, *o*), which is the lower portion enclosing the *ovules* destined to become seeds, and the *stigma* (fig. 176, *g*), a portion of loose cellular tissue uncovered by epidermis, which is either sessile on the apex of the ovary, as in the Poppy, or is separated from it by a prolonged portion called the *style* (fig. 176, *s*). The andrœcium and gynœcium are not present in all flowers. When both are present the flower is *hermaphrodite*; and in descriptive botany such a flower is indicated by the symbol ☿. When Plate XV. Plate I.

only one of those organs is present the flower is *unisexual* or *diclinous*, and is either male (*staminate*), ♂, or female (*pistillate*), ♀. A flower then normally consists of the four whorls of leaves,—calyx, corolla, andrœcium, and gynœcium,—and when these are all present the flower is *complete*. These several whorls of the flower are usually densely crowded upon the thalamus, but in some instances, after apical growth has ceased in the axis, an elongation of portions of the receptacle by intercalary growth occurs, by which changes in the position of the parts may be brought about. Thus in Lychnis an elongation of the axis betwixt the calyx and the corolla takes place, and in this way they are separated by an interval. Again, in Passiflora the stamens are separated from the corolla by an elongated portion of the axis, which has consequently been termed the *androphore;* and in Passiflora, Fraxinella (fig. 177), Capparidaceæ, and some other plants, the ovary is raised upon a distinct stalk termed the *gynophore;* it is thus separated from the stamens, and is said to be *stipitate*. The apical growth of the floral axis in the flower soon ceases, and therefore the parts are arranged in whorls; but at times, as in the Ranunculaceæ, Magnoliaceæ, &c., the growth is of sufficient duration to permit a spiral arrangement of parts. Usually the successive whorls of the flower disposed from below upwards or from without inwards upon the floral axis are of the same number of parts, or are a multiple of the same number of parts, those of one whorl alternating with those of the whorls next it.

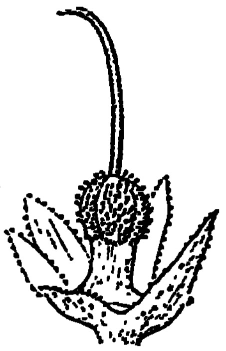

Fig. 177.

Calyx and pistil of Fraxinella (*Dictamnus Fraxinella*). The pistil consists of several carpels, which are elevated on a stalk prolonged from the receptacle. The stalk is called gynophore or thecaphore.

nmetry he er.

When a flower consists of parts arranged in whorls it is said to be *cyclic*, and if all the whorls have an equal number of parts and are alternate it is *eucyclic*. In contrast to the cyclic flowers are those, as in Magnoliaceæ, where the parts are in spirals. When in such a flower the transition from one foliar structure to another, *i.e.*, from calyx to corolla, from corolla to stamens, &c., does not coincide with a definite number of turns of the spiral it is said to be *acyclic;* if it does so correspond it is termed *hemicyclic;* the latter term also includes flowers which are cyclic at one portion and spiral at another, as in many Ranunculaceæ. In spiral flowers the distinction into whorls is by no means easy, and usually there is a gradual passage from sepaloid through petaloid to staminal parts, as in Nymphæaceæ (figs. 178, 179), although in some plants

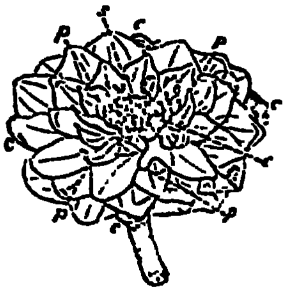

Fig. 178.

Fig. 179.

FIG. 178.—Flower of *Nymphæa alba*, White Water-lily. c, c, c, c, the four foliols of the calyx or sepals; p, p, p, p, petals; e, stamens; s, pistil.

FIG. 179.—Parts of the flower separated to show the transition from the green sepals of the calyx c, and the white petals of the corolla p, to the stamens e. The latter present changes from their perfect state, 5, through intermediate forms, 4, 3, 2, and 1, which gradually resemble the petals.

there is no such distinction, the parts being all petaloid, as in Trollius. We may again note here that some regard the cone in Coniferæ and Cycadaceæ as a single flower, and in that case the whorls are much separated and arranged spirally along the floral axis. Normally, the parts of successive whorls alternate; but in some cases we find the parts of one whorl opposite or *superposed* to those of the next whorl. In some cases, as in the Ampelideæ, this seems to be the ordinary mode of development, but in Caryophyllaceæ the superposition of the stamens on the sepals in many plants seems to be due to the suppression or abortion of the whorl of petals, and this idea is borne out by the development, in some plants of the order, of the suppressed whorl. In Primulaceæ, again, where there is a superposition of stamens and petals the abnormality is due apparently to another cause. The petals are developed after the stamens, and are to be regarded as appendages from them, of the same nature as the appendages to the stamens in Asclepiadaceæ, so that morphologically in Primulaceæ, according to this view, there are no petals. As a rule, whenever we find the parts of one whorl superposed to those of another we may suspect some abnormality. Frequently, when parts are superposed they become adherent to one another; thus the stamens become adherent to the petals or are *epipetalous*, or to the sepals and are *episepalous*.

A flower is said to be *symmetrical* when each of its whorls consists of an equal number of parts, or when the parts of any one whorl are multiples of that preceding it. Thus, a symmetrical flower may have five sepals, five petals, five stamens, and five carpels, or the number of any of these parts may be ten, twenty, or some multiple of five. Fig. 173 is a diagram of a symmetrical flower, with five parts in each whorl, alternating with each other. In fig. 180 there is a section of a symmetrical flower of Stone-crop, with five sepals, five alternating petals, ten stamens, and five carpels. Here the number of parts in the staminal whorl is double that in the others, and in such a case the additional five parts form a second row alternating with the others. In the staminal whorl especially it is common to find additional rows. In fig. 181 there is a

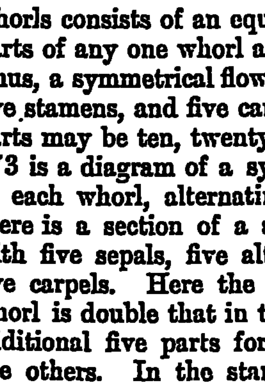

Fig. 180.

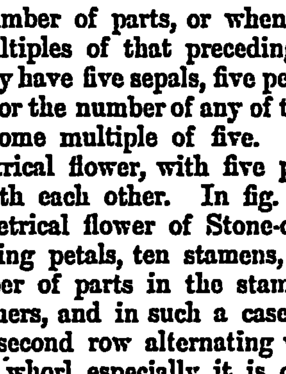

Fig. 181.

FIG. 180.—Diagrammatic section of a symmetrical pentamerous flower of Stone-crop (*Sedum*), consisting of five sepals externally, five petals alternating with the sepals, ten stamens in two rows, and five carpels containing seeds. The dark lines on the outside of the carpels are glands.

FIG. 181.—Diagram of the flower of Flax (*Linum*), consisting of five sepals, five petals, five stamens, and five carpels, each of which is partially divided into two. It is pentamerous, complete, symmetrical, and regular.

symmetrical flower, with five parts in the three outer rows, and ten divisions in the inner. In this case it is the gynœcium which has an additional number of parts. Fig. 182 shows a flower of Heath, with four divisions of the calyx and corolla, eight stamens in two rows, and four divisions of the pistil. In fig. 183 there are three parts in each whorl; and in figs. 184 there are three divisions of the calyx, corolla, and pistil, and six stamens in two rows. In all these cases the flower is symmetrical. Where, as in the Stone-crop, an extra row of parts is developed in any whorl they may be either formed in regular succession within the first row, or they may be interposed to them, *i.e.*, formed between them, or even external to and beneath them. We have examples of the former in many Caryophyllaceous plants, the latter being well seen in Crassulaceæ, Geraniaceæ, &c. In Monocotyledons it is

usual for the staminal whorl to be double, it rarely having more than two rows, whilst amongst Dicotyledons there are often very numerous rows of stamens. The floral envelopes are rarely multiplied Flowers in which the number of parts

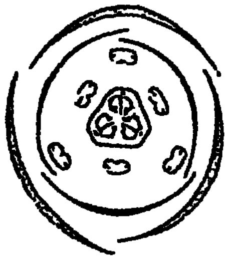

Fig. 184.

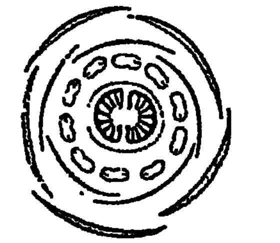

Fig. 185.

FIG. 182—Diagram of the flower of Heath (*Erica*), having four sepals, four divisions of the corolla, eight stamens in two rows, and four divisions of the pistil. The flower is tetramerous, complete, symmetrical, and regular.

FIG. 183.—Diagram of the trimerous symmetrical flower of Iris. There are three alternating divisions of each whorl. Below is a single bract.

FIG. 184.—Diagram of the symmetrical trimerous flower of Fritillary, having three divisions of the two outer whorls, and of the pistil in the centre, and six stamens in two rows.

FIG. 185.—Diagram of the flower of Saxifrage (*Saxifraga tridactylites*). The calyx and corolla consist of five parts, the stamens are ten in two rows, while the pistil has only two parts developed. The flower is, nevertheless, called symmetrical, although the outer whorls are pentamerous, and the central one dimerous

in each whorl is the same, are *isomerous* (of equal number); when the number in some of the whorls is different, the flower is *anisomerous* (of unequal number). The pistilline whorl is very liable to changes. It frequently happens that when it is fully formed, the number of its parts is not in conformity with that of the other whorls. In such circumstances, however, a flower has been called symmetrical, provided the parts of the other whorls are normal, —the permanent state of the pistil not being taken into account in determining symmetry. Thus, fig. 185 shows a pentamerous symmetrical flower, with dimerous pistils. Symmetry, then, in botanical language, has reference to a certain definite numerical relation of parts. A flower in which the parts are arranged in twos, is called *dimerous*, the symmetry being *binary* and the arrangement marked thus ²/. This may be considered either as analogous to opposite decussating leaves, or as composed of distichous alternate leaves belonging to the one-half series. When the parts of the floral whorls are three, the flower is *trimerous*, and the symmetry being *ternary* or trigonal is marked ³/. This may be looked upon as composed of verticillate leaves, or of tristichous alternate leaves with the angular divergence $\frac{1}{3}$. When floral whorls have parts in a series of four, the flower is *tetramerous*, its symmetry being *quaternary*, and marked ⁴/. A *pentamerous* flower, marked ⁵/, has *quinary* or *pentagonal* symmetry. The symmetry which is most commonly met with in the vegetable kingdom is trimerous and pentamerous—the former occurring generally among Monocotyledons, the latter among Dicotyledons. Dimerous or tetramerous symmetry occurs also among Dicotyledonous plants, and the numbers 2 and 4 prevail in the reproductive organs of Acotyledons. The various parts of the flower have a certain definite relation to the axis. Thus, in axillary tetramerous flowers (fig. 182), one sepal is next the axis, and is called *superior* or *posterior*: another is next the bract, and is *inferior* or *anterior*, and the other two are *lateral*; and certain terms are used to indicate that position. A plane passing through the anterior and posterior sepal and through the floral axis is termed the *median plane* of the flower; a plane cutting it at right angles, and passing through the lateral sepals, is the *lateral plane*; whilst the planes which bisect the angles formed by the lateral and median planes are the *diagonal planes*, and in these flowers the petals which alternate with the sepals are cut by the diagonal planes.

In a pentamerous flower one sepal may be superior, as in the calyx of Rosaceæ and Labiatæ; or it may be inferior, as in the calyx of Leguminosæ (fig. 186),—the reverse, by the law of alternation, being the case with the petals. Thus, in the blossom of the Pea (fig. 187), the odd petal (vexil-

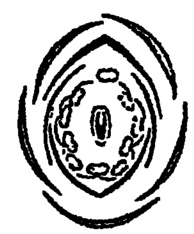

Fig. 186.

Fig. 187.

FIG. 186.—Diagram of flower of Sweet-pea (*Lathyrus*), showing five parts of the calyx, of which two are superior, one inferior, and two lateral; five parts of the corolla, of which one is superior, two inferior, and two lateral; ten stamens in two rows; one carpel, in consequence of four being undeveloped.

FIG. 187.—Flower of Pea (*Pisum sativum*), showing a papilionaceous corolla, with one petal superior, *st*, called the standard (vexillum), two inferior, *car*, called the keel (carina), and two lateral, *a*, called wings (alæ). The calyx is marked *c*.

lum) *st* is superior, while the odd sepal is inferior. In the Figwort order one of the two carpels is posterior and the other anterior, whilst in Convolvulaceæ the carpels are arranged laterally. Sometimes the twisting of a part makes a change in the position of other parts, as in Orchids, where the twisting of the ovary changes the position of the labellum. When the different members of each whorl are like in size and shape, the flower is said to be *regular*; while differences in the size and shape of the parts of a whorl make the flower *irregular*, as in the Papilionaceous flower, represented in fig. 187. When a flower can be divided by a single median plane into two exactly similar parts, then it is said to be *zygomorphic*. Such flowers as Papilionaceæ, Labiatæ, are examples. In contrast with this are *polysymmetrical* flowers, which can be divided by several planes into several exactly similar portions; such are all regular, symmetrical flowers. When the parts of any whorl are not equal to or some multiple of the others, then the flower is *unsymmetrical*. This want of symmetry may be brought about in various ways. A consideration of the various unsymmetrical, irregular, and incomplete forms of the flower, and the processes by which they have been brought about, constitutes *Teratology*. Alteration in the symmetrical arrangement as well as in the completeness and regularity of flowers has been traced to *suppression* or the *non-development* of parts, *degeneration* or imperfect formation, *cohesion* or union of parts of the same whorl, *adhesion* or union of the parts of different whorls, *multiplication* of parts, and *deduplication* (sometimes called *chorisis*) or splitting of parts.

By *suppression* or non-appearance of a part at the place where it ought to appear if the structure was normal, the symmetry or completeness of the flower is disturbed. This suppression when confined to the parts of certain verticils makes the flower unsymmetrical. Thus, in the flowers of Staphylea there are five parts of the calyx, five petals, five stamens, and only two carpels; in many Caryophyllaceæ, as Polycarpon and Holosteum, while the calyx and corolla are pentamerous, there are only three or four stamens and three carpels; in Impatiens noli-me-tangere the calyx is

composed of three parts, while the other verticils have five; in Labiate flowers there are five parts of the calyx and corolla, and only four stamens; and in Tropæolum pentaphyllum there are five sepals, two petals, eight stamens, and three carpels. In all these cases the want of symmetry is traced to the suppression of certain parts. In the last-mentioned plant the normal number is five, hence it is said that there are three petals suppressed, as shown by the position of the two remaining ones; there are two rows of stamens, in each of which one is wanting, and there are two carpels suppressed. In many instances the parts which are afterwards suppressed can be seen in the early stages of growth, and occasionally some vestiges of them remain in the fully developed flower. By the suppression of the verticil of the stamens, or of the carpels, flowers become *unisexual*, or *diclinous*, and by the suppression of one or both of the floral envelopes, monochlamydeous and achlamydeous flowers are produced. The suppression of parts of the flower may be carried so far that at last a flower consists of only one part of one whorl. In the Euphorbiaceæ we have an excellent example of the gradual suppression of parts, where from an apetalous trimerous staminal flower we pass to one where one of the stamens is suppressed, and then to forms where two of them are wanting. We next have flowers in which the calyx is suppressed, and its place occupied by one, two, or three bracts (so that the flower is, properly speaking, achlamydeous), and only one or two stamens are produced. And finally, we find sterile flowers consisting of a single stamen with a bract, and fertile flowers consisting of a single carpel with a bract. There is thus traced a *degradation*, as it is called, from a flower with three stamens and three divisions of the calyx, to one with a single bract and a single stamen or carpel.

Degeneration, or the transformation of parts, often gives rise either to an apparent want of symmetry or to irregularity in form. In unisexual flowers it is not uncommon to find vestiges of the undeveloped stamens in the form of filiform bodies or scales. To many of these staminal degenerations Linnæus gave the name of *nectaries*. In double flowers transformations of the stamens and pistils take place, so that they appear as petals. In Canna, what are called petals are in reality metamorphosed stamens. In the capitula of Compositæ we sometimes find the florets converted into green leaves. The limb of the calyx may appear as a rim, as in some Umbelliferæ; or as pappus, in Compositæ and Valeriana. In Scrophularia the fifth stamen appears as a scale-like body, called *staminodium*; in other Scrophulariaceæ, as in Pentstemon, it assumes the form of a filament, with hairs at its apex in place of an anther.

Cohesion, or the union of parts of the same whorl, and *adhesion*, or the growing together of parts of different whorls, are very common causes of change both as regards form and symmetry. Thus in Cucurbita the stamens are originally five in number, but subsequently some cohere, so that three stamens only are seen in the mature flower. Again, amongst Malvaceæ the stamens cohere by their margins. Cases of what are called gamopetalous corollas, gamosepalous calyces, &c., must be distinguished carefully from such a process as this; for in these cases the parts were never free from one another, but developed from the very first as one mass; and the same caution is necessary in many instances of so-called union of stamens, which are really cases of branching. Adhesion is well seen in the *gynostemium* of Orchids, where the stamens and ovary adhere; and in flowers where the stamens are *perigynous*, *i.e.*, are adherent to the calyx. In Capparidaceæ the calyx and petals occupy their usual position, but the axis is prolonged in the form of a gynophore, to which the stamens are united. Cohesion and adhesion are rare amongst Monocotyledons.

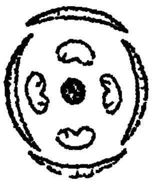
Multiplication, or an increase of the number of parts, gives rise to changes in plants. We have already alluded to the interposition of new members in a whorl. This takes place chiefly in the staminal whorl, but usually the additional parts produced form a symmetrical whorl with the others. In some instances, however, this is not the case. Thus in the Horse-chestnut there is an interposition of two stamens betwixt the other whorl, and thus seven stamens are formed in the flower, which is unsymmetrical.

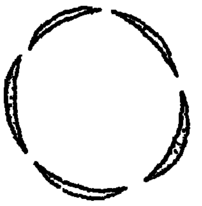
Parts of the flower are often increased by a process of *deduplication*, *unlining*, *dilamination*, or *chorization*, *i.e.*, the splitting of a part so that two or more parts are formed out of what was originally one. This is believed by some to take place in a remarkable degree in the case of appendages to petals. Thus, in Ranunculus, the petal has a scale at its base, which is looked upon as a mere fold of it. This fold may in some cases be more highly developed, as in Caryophyllaceæ, and in Crassula rubens (fig. 172, *a*). Others refer such cases to the formation of outgrowths similar in nature to the ligule in Grasses. In Cruciferous plants a case of chorisis is said to occur. There the staminal whorl consists of four long stamens and two short ones (*tetradynamous*). The symmetry in the flower is evidently dimerous, and the abnormality in the andrœcium, where the four long stamens are opposite the posterior sepals, is said to take place by a splitting of the filaments of two stamens into four; and thus the two long stamens on each side are, by *gemination*, normally one. This view is supported by cases in which the filaments of the long stamens are more or less united; also by cases in which the shorter filaments exhibit tooth-like processes on both sides, while the longer ones have them only on the outer side. In such cases the two long filaments, if united, would present the same appearance as the shorter ones, and occupy their usual position of alternation with the petals. In some instances, by *pelorization*, it is found that tetradynamous plants become tetrandrous, with stamens of equal length alternating with the petals. Many cases of what was considered chorisis are in reality due to the development of stipules from the staminal leaf. Thus in Dicentra and Corydalis there are six stamens in two bundles; the central one of each bundle alone is perfect, the lateral ones have each only half an anther, and they are really stipules formed from the staminal leaf. Branching of stamens also produces apparent want of symmetry; thus, in the so-called polyadelphous stamens of Hypericaceæ there are really only five stamens which give off numerous branches, but the basal portion remaining short, the branches have the appearance of separate stamens, and the flower thus seems unsymmetrical.

Cultivation has a great effect in causing changes in the various parts of plants. Many alterations in form, size, number, and adhesion of parts are due to the art of the horticulturist. The changes in the colour and forms of flowers thus produced are endless. In the Dahlia the florets are rendered quilled, and are made to assume many glowing colours. In Pelargonium the flowers have been rendered larger and more showy; and such is also the case with the Ranunculus, the Auricula, and the Carnation. Some flowers, with spurred petals in their usual state, as Columbine, are changed so that the spurs disappear; and others, as Linaria, in which one petal only is usually spurred, are altered so as to have all the petals spurred, and to present what are called *pelorian* varieties.

As a convenient method of expressing the arrangement of the parts of the flower, floral formulæ have been devised. Several modes of expression are employed. The following is a very simple mode which has been proposed:—The several whorls are represented by the letters S sepals, P petals, St stamens, C carpels, and a figure marked after each indicates the number of parts in that whorl. Thus the formula $S_5P_5St_5C_5$ means that the flower is perfect, and has Floral formulæ

pentamerous symmetry, the whorls being isomerous. Such a flower as that of Sedum (fig. 180) would be represented by the formula $S_5P_5St_{5+5}C_5$, where St_{5+5} indicates that the staminal whorl consists of two rows of five parts each. A flower such as the male flower of the Nettle (fig. 188) would be expressed $S_4P_0St_4C_0$. It is also possible to indicate, in cases where members of a whorl are absent, which of them are wanting; thus, in the flower of an Orchis we have $S_3P_3St_{1+0}C_3$. Here St_{1+0} indicates that the anterior stamen of the outer row is present, the other two stamens of the row, marked as dots, are wanting, as also all the stamens of the inner row. In Cypripedium, on the other hand, the formula is $S_3P_3St_{0+2}C_3$, for here all the stamens of the outer row and the anterior one of the inner row are absent. When no other mark is appended the whorls are supposed to be alternate; but if it is desired to mark the position of the whorls special symbols are employed. Thus, to express the superposition of one whorl upon another, a line is drawn between them, *e.g.*, the symbol $S_5P_5 \mid St_5C_5$ is the formula of the flower of Primulaceæ. To indicate the interposition of a row of parts in a whorl a dot is placed between the coefficients, thus $S_5P_5St_{5\cdot5}C_5$ indicates that an extra row of five stamens has been interposed between those already in existence. To represent adhesions and cohesions leads to complicated formulæ, but in many cases cohesion can be easily indicated. Thus in the formula $\hat{S}_4\hat{P}_4St_2\hat{C}_2$, we have the arrangement of the parts of the flower in Veronica indicated, the sepals and the petals being united and the two carpels also being united into one pistil. The papilionaceous flower, of which fig. 186 is a diagram, may be formulated $\hat{S}_5P_5St_{5+(\overset{\frown}{4}+1)}C_1$. *We thus* learn that there are five sepals united, five free petals, ten stamens in two rows, of which nine are united and one is free, and there is one carpel. When the parts of the flower are arranged spirally on the floral axis, as in Magnoliaceæ and other flowers, the formula is prefixed by a curved line thus ⊂⊃, and then the angle of divergence of the members may be marked in addition to their number. Many other points in the arrangement of the flower may be attached to the formula by different symbols, according to the object which one has in view.





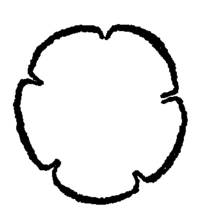


Fig. 188. Fig. 189. Fig. 190.

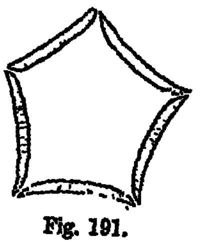
FIG. 188.—Tetramerous male (unisexual) flower of the Nettle (*Urtica*). It is incomplete, as it wants petals and pistil; and it *is said to* be monochlamydeous. One sepal is next *the* axis, and is called *posterior or superior*, another is next the bract, called anterior or inferior, and two are lateral, that is, to the right and left of the axis.
FIG. 189.—Diagram to illustrate valvular or valvate æstivation, in which the parts are placed in a circle, without overlapping or folding.
FIG. 190.—Diagram to illustrate induplicative or induplicate æstivation, in which the parts of the verticil are slightly turned inwards at the edges.

To the flower-bud the name *alabastrus* is sometimes given, and its period of opening has been called *anthesis*, whilst the manner in which the parts are arranged with respect to each other before opening is the *æstivation* or *præfloration*. The latter terms are applied to the flower-bud in the same way as vernation is to the leaf-bud, and distinctive names have been given to the different arrangements exhibited, both by the leaves individually and in their relations to each other. As regards each leaf of the flower, it is either spread out, as the sepals in the bud of the Lime-tree, or folded upon itself (conduplicate), as in the petals of some species of Lysimachia, or slightly folded inwards or outwards at the edges, as in the calyx of some species of Clematis, and of some herbaceous plants, or rolled up at the edges (involute or révolute), or folded transversely, becoming *crumpled* or *corrugated*, as in the Poppy. When the parts *of a* whorl are placed Plate I.
in an exact circle, and are applied to each other by their edges only, without overlapping or being folded, thus resembling the valves of a seed-vessel, the æstivation is *valvate*, as in the calyx of Guazuma ulmifolia (fig. 189). The edges of each of the parts may be turned either inwards or outwards; in the former case, the æstivation is *induplicate*, as in the corolla of Guazuma ulmifolia (fig. 190), in the latter case, *reduplicate*, as in the calyx of Althæa rosea (fig. 191). When the parts of a single whorl are placed in a circle, each of them exhibiting a torsion of its axis, so that by one of its sides it overlaps its neighbour, whilst its side is overlapped in like manner by that standing next to it, the æstivation *is twisted or contortive*, as in the corolla of Althæa rosea (fig. 192). This arrangement is characteristic of the flower-buds of



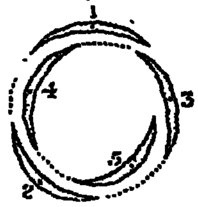


Fig. 191. Fig. 192. Fig. 193.

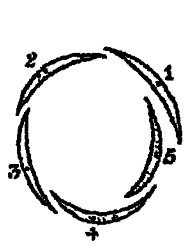
FIG. 191.—Diagram to illustrate reduplicative or reduplicate æstivation, in which the parts of the whorl are *slightly turned outwards* at the edges.
FIG. 192.—Diagram to illustrate contortive or twisted æstivation, *in* which the parts of the whorl *are overlapped* by each other in turn, and are twisted on their axis.
FIG. 193.—Diagram to illustrate the quincuncial æstivation, in which the parts of the flower are arranged in a *spiral cycle, so that* 1 and 2 are wholly external, 4 and 5 are internal, and 3 is partly external and partly overlapped by 1.

Malvaceæ and Apocynaceæ, and it is also seen in Convolvulaceæ and Caryophyllaceæ. When the flower expands, the traces of twisting *often* disappear, but sometimes, as in Apocynaceæ, they remain. Those forms of æstivation are such as occur in cyclic flowers, and they are included under *circular* æstivation. But in spiral flowers we have a different arrangement, the leaves of the calyx of Camellia japonica cover each other partially like tiles on a house. This æstivation is *imbricate*. At other times, as in the petals of Camellia, the parts envelope each other completely, so as to become *convolute*. This is also seen in a transverse section of the calyx of Magnolia grandiflora, where each of the three leaves embraces that within it. When the parts of a whorl are five, as occurs in many Dicotyledons, and



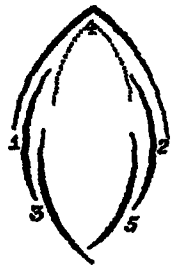


Fig 194. Fig 195.

FIG. 194.—Diagram *to illustrate* imbricative or imbricated æstivation, in which the parts are arranged in a spiral cycle, following the order indicated by the figures 1, 2, 3, 4, 5.
FIG. 195.—Diagram of a papilionaceous flower, showing vexillary æstivation. 1 and 2, the alæ or wings; 3, a part of the carina or keel; 4, the vexillum or standard, which, in place of being internal, as marked by the dotted line, becomes external; 5, *the* remaining part of the keel. The order of the cycle is indicated by the figures.

the imbrication is such that there are two parts external, two internal, and a *fifth* which partially covers one of the internal parts by its margin, and is in its turn partially covered by one of the external parts, the æstivation is *quincuncial* (fig. 193). This quincunx is common in the corolla of Rosaceæ. In fig. 194 a section is given of the

bud of Antirrhinum majus, showing the imbricate spiral arrangement. In this case it will be seen that the part marked 5 has, by a slight change in position, become overlapped by 1. This variety of imbricate æstivation has been termed *cochlear.* In flowers, such as those of the Pea (fig. 187), one of the parts, the vexillum, is often large and folded over the others, giving rise to *vexillary* æstivation (fig. 195), or the carina may perform a similar office, and then the æstivation is *carinal,* as in the Judas-tree (Cercis Siliquastrum). The parts of the several verticils often differ in their mode of æstivation. Thus, in Malvaceæ the corolla is contortive and the calyx valvate, or reduplicate; in St John's-wort the calyx is imbricate, and the corolla contortive. In Convolvulaceæ, while the corolla is twisted, and has its parts arranged in a circle, the calyx is imbricate, and exhibits a spiral arrangement. In Guazuma the calyx is valvate, and the corolla induplicate. The circular æstivation is generally associated with a regular calyx and corolla, while the spiral æstivations are connected with irregular as well as with regular forms.

I. Protective Organs.

1. *Calyx.*

rotective gans. lyx.

The calyx is the external envelope of the flower, and consists of verticillate leaves, called *sepals, foliola,* or *phylla.* These calycine leaves are sometimes separate from each other, at other times they are united to a greater or less extent; in the former case, the calyx is *dialysepalous* or *eleutherosepalous, polysepalous* or *polyphyllous,* or *aposepalous;* in the latter, *gamosepalous* or *gamophyllous, monosepalous* or *monophyllous,* or *synsepalous.* The divisions of the calyx present usually all the characters of leaves, and in some cases of monstrosity they are converted into the ordinary leaves of the plant. Their structure consists of cellular tissue or parenchyma, traversed by vascular bundles, in the form of ribs and veins, containing spiral vessels, which can be unrolled, delicate woody fibres, and other vessels, the whole being enclosed in an epidermal covering, having stomata and often hairs on its outer surface, which corresponds to the under side of the leaf. In the great divisions of the vegetable kingdom the venation of the calyx is similar to that of the leaves,—parallel in Monocotyledons, reticulated in Dicotyledons. The leaves of the calyx are usually entire, but occasionally they are cut in various ways, as in the Rose, and they are sometimes hooked at the margin, as in Rumex uncatus. It is rare to find the leaves of the calyx stalked. They are usually sessile leaves, in which the vaginal portion is only slightly developed, and frequently the laminar part is alone present. Sepals are generally of a more or less oval, elliptical, or oblong form, with their apices either blunt or acute. In their direction they are erect or reflexed (with their apices downwards), spreading outwards (*divergent* or *patulous*), or arched inwards (*connivent*). They are usually of a greenish colour, and are called *foliaceous* or *herbaceous;* but sometimes they are coloured, as in the Fuchsia, Tropæolum, Globe-flower, and Pomegranate, and are then called *petaloid.* Whatever be its colour, the external envelope of the flower must be considered as the calyx. The nature of the hairs on the calyx gives rise to terms similar to those already mentioned as applied to the surfaces of other parts of plants. The vascular bundles sometimes form a prominent rib, which indicates the middle of the sepal; at other times they form several ribs. The venation is useful as pointing out the number of leaves which constitute a gamosepalous calyx. In a polysepalous calyx the number of the parts is marked by Greek numerals prefixed. Thus, a calyx which has three sepals is *trisepalous;* one with five sepals is *pentasepalous* or *pentaphyllous.* The sepals occasionally are of different forms and sizes. In Aconite one of them is shaped like a helmet, and has been called *galeate.* In a gamosepalous calyx the sepals are united in various ways, sometimes very slightly, and their number is marked by the divisions at the apex. These divisions either are simple projections in the form of acute or obtuse teeth; or they extend down the calyx as fissures about halfway, the calyx being *trifid* (three-cleft), *quinquefid* (five-cleft), (fig. 196), &c., according to their number; or they reach to near the base in the form of partitions, the calyx being *tripartite, quadripartite, quinquepartite,* &c. The union of the parts may be complete, and the calyx may be quite entire or *truncate,* as in some Correas, the venation being the chief indication of the different parts. The cohesion is sometimes irregular, some parts uniting to a greater extent than others; thus a two-lipped or *labiate* calyx is formed, which, when the upper or posterior lip is arched, becomes *ringent.* The upper lip is often composed of three parts, which are thus posterior or next the axis, while the lower has two, which are anterior. The part formed by the union of the sepals is called the *tube* of the calyx; the portion where the sepals are free is the *limb.*

Occasionally, certain parts of the sepals undergo marked enlargement. In the Violet the calycine segments (*laciniæ*) are prolonged downwards beyond their insertions, and in the Indian Cress (Tropæolum) this prolongation is in the form of a spur (*calcar*), formed by three sepals; in Delphinium it is formed by one. When one or more sepals are thus enlarged, the calyx is *calcarate* or *spurred.* In Pelargonium the spur from one of the sepals is adherent to the flower-stalk. When an epicalyx is present, as in the Mallow order, the flower appears to be provided with a double calyx, and has been denominated *caliculate.* Degenerations take place in the calyx, so that it becomes dry, scaly, and glumaceous (like the glumes of grasses), as in the Rush tribe; hairy, as in Compositæ; or a mere rim, as in some Umbelliferæ and Acanthaceæ, and in Madder (Rubia tinctorum, fig. 198), when it is called *obsolete* or *marginate.* In Diplolæna it is reduced to five scales. In Compositæ,

Fig. 197. Fig. 199. Fig. 200.

Fig. 196.—Gamosepalous five-toothed (quinque-dentate) calyx of Campion (*Lychnis*).

Fig. 197.—Feathery pappus attached to the fruit of Salsafy (*Tragopogon porrifolius*). The calyx adheres to the fruit, and its limb is pappose.

Fig. 198.—Calyx of Madder (*Rubia*), adherent to the pistil, its limb appearing in the form of a rim. The calyx is called obsolete.

Fig. 199.—Caducous calyx of Poppy (*Papaver*). It is composed of two sepals, which fall off before the petals expand.

Fig. 200.—Bladder-like calyx of the Winter Cherry (*Physalis Alkekengi*), [illegible] to show the mode in which it surrounds the fruit without adhering to it. The calyx is persistent, but not adherent. It enlarges after the flower withers, and is called accrescent.

Dipsaceæ, and Valerianaceæ, the calyx is attached to the pistil, and its limb is developed in the form of hairs, called *pappus* (fig.197). This pappus is either simple [illegible]

Plate VIII feathery (*plumose*). In Valeriana the superior calyx is at first an obsolete rim, but as the fruit ripens it is shown to consist of hairs rolled inwards, which expand so as to waft the fruit. The calyx sometimes falls off before the flower Plate I. expands, as in Poppies, and is *caducous* (fig. 199); or along with the corolla, as in Ranunculus, and is *deciduous*; or it Plate XI. remains after flowering, as in Labiatæ, Scrophulariaceæ, and Boraginaceæ; or its base only is persistent, as in Datura Stramonium. In Eschscholtzia and Eucalyptus the sepals remain united at the upper part, and become disarticulated at the base or middle, so as to come off in the form of a lid or funnel. Such a calyx is *operculate* or *calyptrate*. The existence or non-existence of an articulation determines the deciduous or persistent nature of the calyx. In the case of Eschscholtzia the axis seems to be prolonged so as Plate II. to form a sort of tube, from which the calyx separates. In Eucalyptus the calyx consists of leaves, the laminæ or petioles of which are articulated like those of the Orange, and the separation between the parts occurs at this articulation. The receptacle bearing the calyx is sometimes united to the pistil, and enlarges so as to form a part of the fruit, as in the Apple, Pear, Pomegranate, Gooseberry, &c. In these fruits the withered calyx is seen at the apex. Sometimes a persistent calyx increases much after flowering, and encloses the fruit without being incorporated with it, becoming *accrescent*, as in various species of Physalis (fig. 200); at other times it remains in a withered or *marcescent* form, as in Erica; sometimes it becomes *inflated* or *vesicular*, as in Sea Campion (Silene maritima).

2. *Corolla.*

Corolla The corolla is the more or less coloured inner floral envelope, forming the whorl of leaves between the calyx and the stamens. It is generally the most conspicuous whorl. The gay colours and fragrant odours of flowers are resident in it. It is present in the greater number of Dicotyledons. Petals differ more from leaves than sepals do, and are much more nearly allied to the staminal whorl. In some cases, however, they are transformed into leaves, like the calyx, and occasionally leaf-buds are developed in their axil. They are seldom green, although occasionally that colour is met with, as in some Cobæas, Hoya viridiflora, Gonolobus viridiflorus, and Pentatropis spiralis. As a rule they are highly coloured, the colouring matter being contained in cells, and differing in its nature from the chlorophyll of the leaves. As regards their structure petals consist of cellular tissue, traversed by true spiral vessels and thin-walled tubes. In delicate flowers, as Convolvulus and Anagallis, these vessels are easily seen under the microscope. Petals do not usually present numerous layers of cells like the leaves, neither is the epidermis always distinct, although in some instances it may be detached, especially from the surface next the calyx. The cuticle of the petal of a Pelargonium, when viewed with a $\frac{1}{2}$ or $\frac{1}{4}$-inch object glass, shows beautiful hexagons, the boundaries of which are ornamented with several inflected loops in the sides of the cells

On the outer surface of petals, corresponding to the lower side of leaves, stomata are sometimes found. Petals are generally glabrous or smooth; but, in some instances, hairs are produced on their surface. Petaline hairs, though sparse and scattered, present occasionally the same arrangement as those which occur on the leaves; thus, in Bombaceæ they are stellate. Coloured hairs are seen on the petals of Menyanthes, and on the segments of the perianth of the Iris. Although petals are usually very thin and delicate in their texture, they occasionally become thick and fleshy, as in Stapelia and Rafflesia; or dry, as in Heaths; or hard and stiff, as in Xylopia. A petal often consists of two portions—the lower narrow, resembling the petiole of a leaf, and called the *unguis* or *claw*; the upper broader, like the blade of a leaf, and called the *lamina* or *limb*. These parts are seen in the petals of the Wallflower (fig. 201), where *c* is the claw and *l* the limb. The claw is often wanting, as in the Crowfoot (fig. 202) and the Poppy, and the petals are Plate I then *sessile*. Petals having a claw are *unguiculate*. According to the development of veins and the growth of cellular tissue, petals present varieties similar to those already noticed in the case of leaves. Thus the margin is either entire or divided into lobes or teeth. These teeth sometimes form a regular fringe round the margin, and the petal becomes *fimbriated*, as in the Pink; or *laciniated*, as in Lychnis Flos-cuculi; or *crested*, as in Polygala. Sometimes the petal becomes pinnatifid, as in Schizopetalum. The median vein is occasionally prolonged beyond the summit

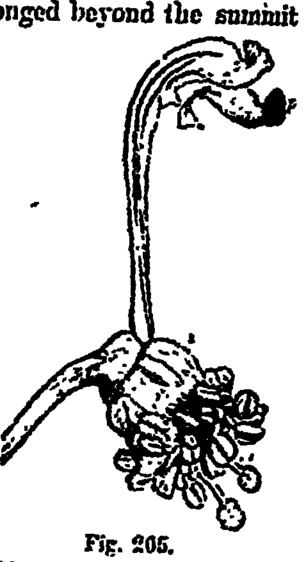

Fig. 205.

FIG. 201.—Unguiculate or stalked petal of Wallflower (*Cheiranthus Cheiri*). *c*, the claw or unguis; *l*, the blade or lamina.
FIG. 202.—Petal of Crowfoot (*Ranunculus*), without a claw, and thus resembling a sessile leaf. At the base of the petal a nectariferous scale is seen.
FIG. 203.—Tubular petal of Hellebore (*Helleborus*), formed by folding and adhesion, in the same manner as pitchers
FIG. 204.—Horn-like hollow petal of Columbine (*Aquilegia vulgaris*), formed by folding and adhesion of the edges.
FIG. 205.—Part of the flower of Aconite (*Aconitum Napellus*), showing two irregular horn-like petals *p*, supported on grooved stalks *o*. These used to be called nectaries. *s*, the whorl of stamens inserted on the thalamus, and surrounding the pistil.

of the petals in the form of a long process, as in Strophanthus hispidus, where it extends for 7 inches; and at other times it ends in a free point or *cuspis*, and the petal becomes *cuspidate*; or the prolonged extremity is folded downwards or inflexed, as in Umbelliferæ, so that the apex approaches the base. The limb of the petal may be flat or concave, or hollowed like a boat. In Hellebore the petals become folded in a tubular form, resembling a horn (fig. 203); in Aconite (fig. 205) some of the petals resemble a hollow-curved horn, supported on a grooved stalk; while in Columbine (fig. 204), Violet, Snapdragon, and Centranthus, one or all of them are prolonged in the form of a spur, and are *calcarate*. In Valeriana, Antirrhinum, and Corydalis, Plate VIII the spur is very short, and the corolla or petal is said to be *gibbous*, or *saccate*, at the base.

A corolla rarely consists of one petal, and when this occurs, as in Amorpha, it depends on the abortion or non-development of others. Such a corolla is *unipetalous*, a term quite distinct from monopetalous. A corolla is *dipetalous*, *tripetalous*, *tetrapetalous*, or *pentapetalous*, according as it has two, three, four, or five separate petals. The general name of *polypetalous*, *dialypetalous*, *eleutheropetalous*, or *apopetalous*, is given to corollas having separate petals, while *monopetalous*, *gamopetalous*, or *sympetalous* is applied to those in which the petals are united. This union generally takes place at the base, and extends more or less towards the apex; in Phyteuma the petals are united at their apices also. In some polypetalous corollas, as that of the Vine, the petals are separate at the base, and

adhere by the apices. When the petals are equal as regards their development and size, the corolla is *regular;* when unequal, it is *irregular.* When a corolla is gamopetalous, it usually happens that the claws are united into a tube, while the upper parts are either free or partially united, so as to form a common limb, the point of union of the two portions being the *faux* or *throat,* which often exhibits a distinct constriction or dilatation. The number of parts forming such a corolla can be determined by the divisions, whether existing as teeth, crenations, fissures, or partitions, or if, as rarely happens, the corolla is entire, by the venation. The union may be equal among the parts, or some may unite more than others.

Amongst regular polypetalous corollas may be noticed the *rosaceous* corolla (fig. 206), in which there are five spreading petals, having no claws, and arranged as in the single Rose and Potentilla; the *caryophyllaceous* corolla, in which there are five petals with long narrow tapering claws, as in many of the Pink tribe; the *alsinaceous,* where the claw is less narrow, and there are distinct spaces between the petals, as in some species of Chickweed; the *cruciform,* having four petals, often unguiculate, placed opposite in the form of a cross, as seen in Wallflower, and in other plants called *cruciferous.* Of irregular polypetalous corollas the
V. most marked is the *papilionaceous* (fig. 187), in which there are five petals:—one superior (posterior), *st,* placed next to the axis, usually larger than the rest, called the *vexillum* or *standard;* two lateral, *a,* the *alæ* or wings; two inferior (anterior), partially or completely covered by the alæ, and often united slightly by their lower margins, so as to form a single keel-like piece, *car,* called *carina* or keel, which embraces the essential organs. This form of corolla is characteristic of British Leguminous plants. Among the irregular polypetalous corollas might be included the *orchideous* (fig. 207), although it is really the perianth of a Monocotyledon. This perianth consists of three outer portions equivalent to the calyx, and three inner parts alternating with them, constituting the petals. The latter are often very irregular, some being spurred, others hooded, &c.; and there is always one, called the *labellum* or lip *l,* which presents a remarkable development, and gives rise to many of the anomalous forms exhibited by these flowers.

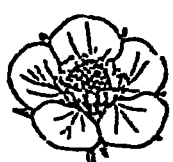

Fig. 206.

Fig. 207.

Fig. 208.

FIG. 206.—Rosaceous corolla of the Strawberry (*Fragaria vesca*), composed of five petals without claws.
FIG. 207.—Flower of Twayblade (*Listera ovata*), seen in front, showing a large bifid labellum *l,* which is different from the other five divisions of the perianth. The divisions of the perianth are in two rows of three each. The essential organs of reproduction are placed on a column opposite the labellum. The perianth is irregular polyphyllous, and is denominated orchideous.
FIG. 208.—Regular gamopetalous bell-shaped (campanulate) corolla of Harebell (*Campanula rotundifolia*). It is composed of five petals united. The ovary is inferior, and is united to the calyx *c.*

Regular gamopetalous corollas are sometimes *campanulate* or *bell-shaped,* as in Campanula rotundifolia (fig. 208): *infundibuliform* or *funnel-shaped,* when the tube is like an inverted cone, and the limb becomes more expanded at the apex, as in Tobacco; *hypocrateriform* or *salver-shaped,* when there is a straight tube surmounted by a flat spreading limb, as in Primula (fig. 209); *tubular,* having a long cylindrical tube, appearing continuous with the limb, as in Spigelia and Comfrey; *rotate* or *wheel-shaped,* when the tube is very short, and the limb flat and spreading, as in Myosotis (when the divisions of the rotate corolla are very acute, as in Galium, it is sometimes called *stellate* or *star-like*); *urceolate* or *urn-shaped,* when there is scarcely any limb, and the tube is narrow at both ends, and expanded in the middle, as in Bell-heath (Erica cinerea). Some of these forms may become irregular in consequence of certain parts being more developed than others. Thus, in Veronica, the rotate corolla has one division much smaller than the rest, and in Digitalis there is a slightly irregular campanulate corolla which some have called *digitaliform.* Plate XI.
Of irregular gamopetalous corollas there may be mentioned the *labiate* or *lipped* (fig. 210), having two divisions of the limb in the form of what are called *labia* or lips (the upper one, *u,* composed usually of two united petals, and the lower, *l,* of three), separated by a *hiatus* or gap. In such cases the tube varies in length, and the parts in their union follow the reverse order of what occurs in the calyx, where two sepals are united in the lower lip, and three in the upper. When the upper lip of a labiate corolla is much arched, and the lips separated by a distinct gap, it is called *ringent* (fig. 210). The labiate corolla characterizes the

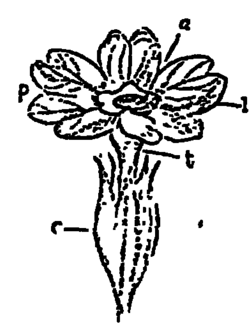

Fig. 209.

Fig. 210.

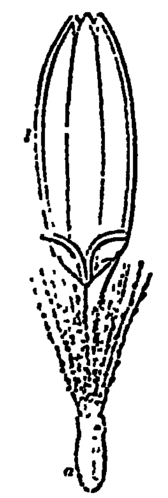

Fig. 211.

FIG. 209.—Regular gamopetalous sympetalous hypocrateriform corolla of Oxlip (*Primula elatior*). *c,* calyx; *p,* corolla; *t,* tube of corolla; *l,* limb; *a,* anthers.
FIG. 210.—Irregular gamopetalous labiate corolla of the Dead-nettle (*Lamium album*). The upper lip *u* is composed of two petals united, the lower lip *l,* of three. Between the two lips (labia) there is a gap (hiatus). The throat is the part where the tube and the labiate limb join. From the arching of the upper lip this corolla is called ringent.
FIG. 211.—Irregular gamopetalous ligulate flower of Ragwort (*Senecio*). It is a tubular floret, split down on one side, with the united petals forming a strap-like projection *l.* The lines on the flat portion indicate the divisions of the five petals. From the tubular portion below, the bifid style projects slightly. The terete fruit (achænium) *a* is surmounted by silky pappus, which is the metamorphosed calycine limb. The flower is female, having no stamens.

natural order Labiatæ. When the lower lip is pressed against the upper, so as to leave only a chink or *rictus* between them, the corolla is said to be *personate* or *mask-like,* as in Frogsmouth, Snapdragon, and some other Scrophulariaceæ, and the projecting portion of the lower lip is called the *palate.* In some corollas the two lips become hollowed out in a remarkable manner, as in Calceolaria, assuming a slipper-like appearance, similar to what occurs in the labellum of some Orchids, as Cypripedium. The *calceolate* corolla of Calceolaria may be considered as consisting of two slipper-like lips. When a tubular corolla is split in such a way as to form a strap-like process on one side with several tooth-like projections at its apex, it becomes *ligulate,* or *strap-shaped* (fig. 211).

This corolla occurs in many Composite plants, as in the florets of Dandelion, Daisy, and Chicory. The number of divisions at the apex indicates the number of united petals, some of which, however, may be abortive. Occasionally some of the petals become more united than others, and then the corolla assumes a *bilabiate*, or two-lipped form, as seen in the division of Compositæ called Labiatifloræ. Plate IX.

In Grasses and Sedges, in place of verticillate leaves forming the flower, there are alternate scales or glumes. The flowers of Grasses usually occur in spikelets (fig. 212), which consist of one or two glumes *a*, covering several flowers *b*. The spikelets are associated in spikes or panicles. In Wheat these spikelets are arranged alternately along a common rachis. Each spikelet consists of two empty glumes *a*, *a*, having the form represented in fig. 212, and enclosing flowers composed of scales (*paleæ*

Fig. 213.

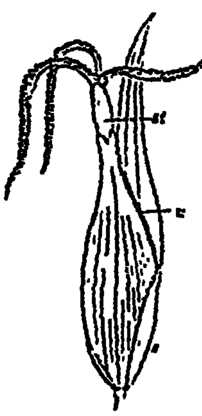

Fig. 214.

FIG. 212.—A spikelet of Wheat (*Triticum*), consisting of two glumes *a*, *a*, enclosing several flowers *b*, *b*, which are composed of two pales (paleæ) covering the essential organs of reproduction. The stamens *s* hang out by long, slender, thread-like filaments. The individual glumes and paleæ are placed alternately on the floral axis.

FIG. 213.—Flower of Oat (*Avena sativa*), with the two glumes, and the outer glumella or palea removed. The inner glumella, flowering glume, or palea *pi*, is seen, of a lanceolate form, and bidentate at the apex. By removing the outer glumella there are seen two *scales* (lodiculæ, squamæ) *sq*, with the three stamens and two feathery styles.

FIG. 214.—Pistilliferous or pistillate flower of a Sedge (*Carex*) with a single glume or scale *s*. The pistil is covered by an urceolate glumaceous bag *u*, called perigynium. There is one style *st*, with three stigmas at its summit.

or *glumellæ*), which are placed at different heights in an alternate manner. In the flower of the Oat (fig. 213), after removing the outer pale or *glumellæ*, the inner one *pi* is seen with two scales (*lodiculæ* or *squamæ*) *sq*, at the base, enclosing the essential organs of reproduction. The paleæ of grasses are called by some flowering glumes, while hypogynous scales (lodiculæ) within them are considered as the rudimentary perianth. In Wheat (Triticum) there are two empty glumes and two flowering glumes, or, as some say, one flowering glume and one pale. In the Oat (Avena) there are two empty glumes, usually three flowering glumes with awns, and two lodicules representing the perianth. In Sedges (Carices) the male flowers are borne on scales, and so are the female, as shown in fig. 214, in which the scale *s* is placed on one side. Within the scale the female flower is situated, having a peculiar bag-like covering *u*, termed perigynium.

The parts of the corolla frequently adhere to those of the calyx, and any change in the latter causes also an alteration in the former. Petals are sometimes suppressed, and sometimes the whole corolla is absent. In Amorpha and Afzelia the corolla is reduced to a single petal, and in some other Leguminous plants it is entirely wanting. In the natural order Ranunculaceæ, some genera, such as Ranunculus, Globe-flower, and Pæony, have both calyx and corolla, while others, such as Clematis, Anemone, and Caltha, have only a coloured calyx. Flowers become double by the multiplication of the parts of the corolline whorl. This arises in general from a metamorphosis of the stamens. Union of separate flowers (*synanthos*) occasionally occurs, and the adhesion which thus takes place causes various changes in the whorls. Flowers may be united by their peduncles, as seen in some anomalous specimens of Dandelion, Hyacinth, and Centaury; or by their outer parts, such as the calyx. At other times there is a complete fusion, as it were, of all the parts of the flowers, some continuing normal, others being suppressed or abortive.

Certain abnormal appearances occur in the petals of some flowers, which received in former days the name of *nectaries*. Nectaries.
The term nectary was very vaguely applied by Linnæus to any part of the flower which presented an unusual aspect, as the crown (*corona*) of Narcissus, the fringes of the Passion-flower, &c. If the name is retained it ought properly to include only those parts which secrete a honey-like matter, as the glandular depression at the base of the perianth of the Fritillary, or on the petal of Ranunculus, or on the stamens of Rutaceæ. The honey secreted by flowers attracts insects, which, by conveying the pollen to the stigma, effect fertilization. What have usually, however, been called nectaries, are mere modifications of some part of the flower, especially of the corolla and stamens, produced either by degeneration or outgrowth, or by *dilamination*, *chorisis*, or *deduplication*. Of this nature are the scales on the petals in Lychnis, Silene, Cynoglossum, and Ranunculus (fig. 202). Others consider these outgrowths of the petal to be formed in the same way as the ligules of Grasses. Corollas having these scaly appendages are sometimes denominated *appendiculate*. In Cuscuta and Samolus Plate I.
the scales are alternate with the petals, and may represent altered stamens. The parts formerly called nectaries are mere modifications of the corolla or stamens. Thus the so-called horn-like nectaries under the galeate sepal of Aconite (fig. 205) are modified petals, so also are the tubular nectaries of Hellebore (fig. 203). The nectaries of Menyanthes and of Iris consist of hairs developed on the petals. Those of Parnassia and the Passion-flower, Stapelia, Asclepias, and Canna, are fringes, rays, and processes, which are probably modifications of stamens; and some consider the crown of Narcissus as consisting of a membrane similar to that which unites the stamens in Pancratium. It is sometimes difficult to say whether these nectaries are to be referred to the corolline or to the staminal row. The paraphyses of the Passion-flower, the crown of Narcissus, and the coronet of Stapelia are referred sometimes to the one and sometimes to the other. In general, they may be said to belong to that series with which they are immediately connected. Some have given names indicating the parts of which they are modifications, by prefixing the term *para*, using such terms as *paracorolla* and *parastemones*.

Petals are attached to the axis usually by a narrow base, but occasionally the base is larger than the limb, as in the Orange flower. When this attachment takes place by an articulation, the petals fall off either immediately after expansion (*caducous*), or after fertilization (*deciduous*). A corolla which is continuous with the axis and not articulated to it, as in Campanula and Heaths, may be persistent, and remain in a withered or marcescent state while the fruit is ripening. A gamopetalous corolla falls off in one piece; but sometimes the base of the corolla remains persistent, as in Rhinanthus and Orobanche.

II. ESSENTIAL ORGANS.

These organs are the *stamens* and the *pistil*, the latter Essential organs.
containing the seeds or germs of young plants, and corresponding to the female, while the former produces a powder necessary for fecundation, and is looked upon as performing part of the male. The presence of both is required in

order that perfect seed may be produced. A flower may have a calyx and corolla, but it will be imperfect if the essential organs are not present. The name of *hermaphrodite* or *bisexual* is given to flowers in which both these organs are found; that of *unisexual* or *diclinous* to those in which only one of these organs appears,—those bearing stamens only, being *staminiferous* or male; those having the pistil only, *pistilliferous* or female. But even in plants with hermaphrodite flowers it is rare that self-fertilization takes place, and this is provided against by the structure of the parts or by the period of ripening of the organs. For instance, in Primula and Linum some flowers have long stamens and a pistil with a short style, the others having short stamens and a pistil with a long style. The former occur in what are called thrum-eyed Primroses, the latter in those called pin-eyed. Such plants are called *dimorphic*. Other plants are *trimorphic*, as species of Lythrum, and proper fertilization is only effected by combination of parts of equal length. In some plants the stamens are perfected before the pistil; they are called *proterandrous*, as in Ranunculus repens, Silene maritima, Zea Mays. In other plants the pistil is perfected before the stamens, as in Potentilla argentea, Plantago major, Coix Lachryma, and they are *proterogynous* plants. Plants in which proterandry or proterogyny occurs are called *dichogamous*. When in the same plant there are unisexual flowers, both male and female, the plant is said to be *monœcious* or *monoicous*, as in the Hazel and Castor-oil plant. This is indicated by the symbol ♂ – ♀. When the male and female flowers of a species are found on separate plants, the term *diœcious* or *dioicous* is applied, as in Mercurialis and Hemp, and the symbol ♂ : ♀ is used; and when a species has male, female, and hermaphrodite flowers on the same or different plants, as in Parietaria, it is *polygamous*, for which ♂ ♀ ☿ is the symbol.

1. *Male Organs in Phanerogams.*

The stamens (*stamina*) arise from the thalamus or torus within the petals, with which they alternate, forming one or more verticils or whorls, which collectively constitute the *andrœcium*, or the male organs of the plant. Their normal position is below the inner whorl or the pistil, and when they are so placed (fig. 215, *e*) upon the thalamus they are *hypogynous*. Sometimes they become adherent to the petals, or are *epipetalous*, and the insertion of both is looked upon as similar, so that they are still hypogynous provided they are independent of the calyx and the pistil. Frequently the margins of the thalamus bearing the floral envelopes and stamens elongates, and the gynœcium remains in the centre of the concave receptacle; thus the stamens as it were rise from the calyx, and they surround the ovary, and are *perigynous*; but when the ovary becomes completely inferior by the growing upwards and inwards of the receptacle, the parts of the flower rising from its summit, the stamens are *epigynous* (fig. 216). Numerous intermediate forms occur, especially amongst Saxifragaceæ, where the parts are *half superior* or *half inferior*. In the Orchis tribe, where the stamens become adherent to the pistil so as to form a column, the flowers are said to be *gynandrous*. The same is the case in Aristolochia (fig. 217). These arrangements of parts are of great importance in classification. The stamens vary in number, from one to many hundreds. Like the other parts of the flower they are modified leaves, resembling leaves in their structure, development, and arrangement. They consist of cellular and vascular tissues. They appear at first in the form of cellular projections, and are arranged in a more or less spiral form. In their general aspect they have a greater resemblance to petals than to the leaves, and there is often seen a gradual transition from petals to stamens, especially in spiral flowers, as Nymphæa alba. When flowers become double by cultivation, the stamens are converted into petals, as in the Pæony, Camellia, Rose, &c. When there is only one whorl the

FIG. 215.—Section of a flower of *Geranium Robertianum*. *c*, *c*, calyx; *p*, petals; *e*, stamens. The pistil is composed of ovary *o*, and style and stigmata *s*. *t* is the torus or thalamus. The petals and stamens are hypogynous, and the latter are monadelphous.

FIG. 216.—Section of the flower of *Aralia spinosa*. Letters as in last figure. The petals and stamens are epigynous, attached to the torus *d*, which covers the summit of the ovary. The ovary is adherent to the torus, and has been laid open to show its loculaments and pendulous ovules.

FIG. 217.—Essential organs of Birthwort (*Aristo'ochia*). Above the ovary *b*, are the stamens united in a column with the style at *a*, so as to be gynandrous. On the summit is the stigma above the stamens.

stamens are usually equal in number to the sepals or petals, and are arranged opposite to the former, and alternate with the latter. The flower is then *isostemonous*. When the stamens are not equal in number to the sepals or petals, the flower is *anisostemonous*. When there is more than one whorl of stamens, then the parts of each successive whorl alternate with those of the whorl preceding it. The staminal row is more liable to multiplication of parts than the outer whorls. A flower with a single row of stamens is *aplostemonous*. If the stamens are double the sepals or petals as regards number, the flower is *diplostemonous*; if more than double, *polystemonous*. The additional rows of stamens may be developed in the usual centripetal (acropetal) order, as in Rhamnaceæ; or they may be interposed between the pre-existing ones or be placed outside them, *i.e.*, develop centrifugally (basipetally), as in Geranium and Oxalis. When the stamens are neither equal to, nor a multiple of, the floral envelopes, but are less numerous, the flower is *miostemonous*. When the stamens are fewer than twenty they are said to be *definite*, and the flower is *oligandrous*; when above twenty they are *indefinite* or *polyandrous*, and are represented by the symbol ∞. The number of stamens is indicated by the Greek numerals prefixed to the term *androus*; thus a flower with

1 stamen is Monandrous (Hippuris, Centranthus);
2 stamens is Diandrous (Veronica, Calceolaria, Circæa);
3 stamens is Triandrous (Grasses, Iris, Valeriana);
4 stamens is Tetrandrous (Alchemilla, Galium, Plantago);
5 stamens is Pentandrous (Primula, Umbelliferæ, Campanula);
6 stamens is Hexandrous (Tulip, Lilium, Juncus);
7 stamens is Heptandrous (Trientalis, Horse-chestnut);
8 stamens is Octandrous (Heath, Fuchsia, Epilobium);
9 stamens is Enneandrous (Butomus, some Lauraceæ);
10 stamens is Decandrous (Saxifraga, Dianthus, Oxalis);
12 stamens is Dodecandrous (Asarum, Agrimonia, Reseda);
20 stamens is Icosandrous (Strawberry, Potentilla, Cratægus);
Numerous and indefinite stamens is Polyandrous ∞ (Poppy).

The simplest form of stamens is seen in Cycadaceous plants, where cataphyllary leaves (the scales of the cone) [illegible] are the staminal leaves, bearing the pollen-sacs scattered over their under surface. The stamen usually consists of two parts, a contracted portion, often thread-like, termed the

filament (fig. 175, *f*), and a broader portion, usually of two lobes, termed the *anther* (fig. 175, *a*), containing a powdery matter, called *pollen* (*p*), and supported upon the end of the filament. That portion of the filament in contact with the anther lobes is termed the *connective*. The exact morphological relations of these parts is not definitely settled. Some consider the filament as representing the petiole, and the anther as being the folded lamina; others again regard the connective as representing the lamina, the rest of the filament being the petiole, and the anther lobes as mere appendages of the lamina. The filament is no more essential to the stamen than the petiole is to the leaf, or the claw to the petal. If the anther is absent the stamen is abortive, and cannot perform its functions. The anther is developed before the filament, and when the latter is not produced, the anther is sessile, or has no stalk, as in the Mistleto.

The filament.

The *filament*, when structurally considered, is found to consist of a thin epidermis, on which occasionally stomata and hairs occur, and a layer of cellular tissue enclosing a bundle of spiral vessels, which traverses its whole length, and terminates at the junction between the filament and the anther. The filaments of Callitriche verna are said to have no vessels. The filament is usually, as its name imports, filiform or thread-like, cylindrical, or slightly tapering towards its summit. It is often, however, thickened, compressed, and flattened in various ways, becoming *petaloid* in Canna, Maranta, Nymphæa alba (fig. 179); *subulate* or slightly broadened at the base, and drawn out into a point like an awl, as in Butomus umbellatus; *clavate*, that is, narrow below and broad above, as in Thalictrum. In some instances, as in Tamarix gallica, Peganum Harmala, and Campanula, the base of the filament is much dilated, and ends suddenly in a narrow thread-like portion. In these cases the base may represent the sheath or vagina of the leaf, and may give off stipulary processes in a lateral direction, as in Allium and Alyssum calycinum. The filament varies much in length and in firmness. The length sometimes bears a relation to that of the pistil, and to the position of the flower, whether erect or drooping. The filament is usually of sufficient solidity to support the anther in an erect position; but sometimes, as in Grasses, it is very delicate and capillary, or hair-like, so that the anther is pendulous (fig. 212, *s*). The filament is generally continuous from one end to the other, but in some cases it is bent or jointed, becoming *geniculate*; at other times, as in the Pellitory, it is spiral. It is frequently colourless; but, in many instances, it exhibits different colours. In Fuchsia and Poinciana, it is red; in Adamia and Tradescantia virginica, blue; in Œnothera and Ranunculus acris, yellow.

Hairs, scales, teeth, or processes of different kinds are sometimes developed on the filament. In Tradescantia virginica, or Spiderwort, the hairs are beautifully coloured, moniliform or necklace-like, and *rotation* is seen in them (p. 84). Such a filament is bearded or *stupose*. At the base of the filament glandular or scaly appendages are occasionally produced, either on its internal or its external surface. These may be either parts of a whorl, to be afterwards noticed under the name of the disk, or separate prolongations from the filament itself, which is hence called *appendiculate*, or sometimes *strumose*. Filaments are usually articulated to the thalamus or torus, and the stamens fall off after fertilization; but in Campanula and some other plants they are continuous with the torus, and the stamens remain persistent, although in a withered state. Changes are produced in the whorl of stamens by cohesion of the filaments to a greater or less extent, while the anthers remain free; thus, all the filaments of the andrœcium may unite, forming a tube round the pistil, or a central bundle when the pistil is abortive, the stamens becoming *monadelphous*, as occurs in plants of the Mallow tribe; or Plate III. they may be arranged in two bundles, the stamens being *diadelphous*, as in Polygala, Fumaria, and Pea; in this case the bundles may be equal or unequal. It frequently happens, especially in Papilionaceous flowers, that out of ten stamens nine are united by their filaments, while one (the posterior one) is free (fig. 218). When there are three or more bundles the stamens are *triadelphous*, as in Hypericum ægyptiacum, or *polyadelphous*, as in Luhea paniculata and Ricinus communis. In some cases, especially in the Mallow tribe, the stamens cohere, having been originally separate, but in most other cases each bundle is produced by the branching of a single stamen. When there are three stamens in a bundle we may conceive the lateral ones as of a stipulary nature. In Lauraceæ there are perfect stamens, each having at the base of the filament two abortive stamens or staminodes, which may be analogous to stipules. Filaments sometimes are adherent to the pistil, forming a *columna* or column, as in Stylidium, Asclepiadaceæ, Rafflesia, Orchidaceæ, and Aristolochiaceæ (fig. 217). The column is called *gynostemium*, and the flowers are denominated *gynandrous*.

The anther.

The *anther* consists of lobes containing minute powdery matter, called *pollen*, which, when mature, is discharged by a fissure or opening of some sort. The anther-lobes are considered by some as formed by the two halves of the lamina, their back corresponding to the under surface, and their face to the upper surface, united by the midrib, the pollen being the cellular tissue, and the fissure of the anther taking place at the margin, which, however, is often turned towards the face. In this view, the two cavities which are found to exist in each lobe may correspond with the upper and under layer of cells, separated by a septum equivalent to the fibro-vascular layer of the leaf. Others view the anther as formed by each half of the lamina being folded upon itself, so that the outer surface of both face and back corresponds to the lower side of the leaf, and the septum dividing each cavity into two is formed by the united upper surfaces of the folded half. Again, others hold that the connective represents the lamina of the leaf to which the anther lobes are mere appendages. There is a double covering of the anther—the outer, or *exothecium*, resembles the epidermis, and often presents stomata and projections of different kinds (fig. 219); the inner, or *endothecium*, is

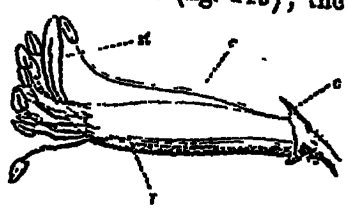

Fig. 218.

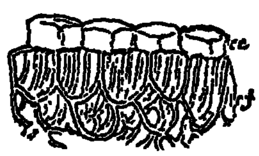

Fig. 219.

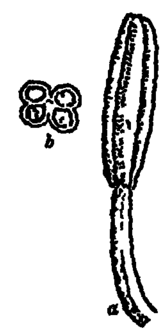

Fig. 220.

FIG. 218.—Stamens and pistil of Sweet Pea (*Lathyrus*). The stamens are diadelphous, nine of them being united by their filaments *f*, while one of them, *c*, is free; the upper part of the pistil is marked *st*, the calyx, *c*.

FIG. 219.—Broken-down fibrous cells *cf* of the endothecium of the anther of the Melon. The walls of the cells are absorbed, and the fibres are set free. The exothecium or outer epidermis is marked *ce*.

FIG. 220.—Quadrilocular or tetrathecal anther of the flowering Rush (*Butomus umbellatus*). The anther entire, *a*, with its filament; section of anther, *b*, showing the four loculi.

formed by a layer or layers of cellular tissue (fig. 219, *cf*), the cells of which have a spiral, annular, or reticulated fibre in their interior. This internal lining varies in thickness,

generally becoming thinner towards the part where the anther opens, and there disappears entirely. The walls of the cells are frequently absorbed, so that when the anther attains maturity the fibres are alone left, and these by their elasticity assist in discharging the pollen. The anther is developed before the filament, and is always sessile in the first instance, and sometimes continues so. It appears at first as a simple cellular papilla of meristem, upon which an indication of two lobes soon appears. Upon these projections the rudiments of the pollen-sacs are then seen, usually four in number, two on each lobe. In each a differentiation takes place in the layers beneath the epidermis, by which an outer layer of small-celled tissue surrounds an inner portion of large cells. Those central cells are the mother-cells of the pollen, whilst the small-celled layer of tissue external to them becomes the endothecium, the exothecium being formed from the epidermal layer.

In the young state there are usually four pollen-sacs or cavities produced, two for each anther-lobe, and when these remain permanently complete, it is a *quadrilocular* or *tetrathecal* anther (fig. 220). The four cavities are sometimes placed in apposition, as in Poranthera, and Tetratheca juncea, and at other times two are placed above and two below, as in Persea gratissima. Sometimes, however, only two cavities remain in the anther, by union of the sacs in each lobe, in which case the anther is said to be *bilocular* or *dithecal*. Sometimes the anther has a single cavity, and becomes *unilocular*, or *monothecal*, or *dimidiate*, either by the disappearance of the partition between the two lobes, or by the abortion of one of its lobes, as in Styphelia læta and Althæa officinalis. Occasionally there are numerous cavities in the anther, as in Viscum and Rafflesia. The form of the anther-lobes varies. They are generally of a more or less oval or elliptical form, or they may be globular, as in Mercurialis annua; at other times linear or clavate, curved, flexuose, or sinuose or *anfractuose*, as in Bryony and Gourd. According to the amount of union of the lobes and the unequal development of different parts of their surface an infinite variety of forms are produced. That part of the anther to which the filament is attached, and which is generally towards the petals, is the *back*, the opposite being the *face*. The division between the lobes is marked on the face of the anther by a groove or *furrow*, and there is usually on the face a *suture*, indicating the line where the membranous coverings open to discharge the pollen. The suture is often towards one side in consequence of the valves being unequal. The stamens may cohere by their anthers, and become *syngenesious* or *synantherous*, as in Composite flowers, and in Lobelia, Jasione, Viola, &c.

The anther-lobes are united to the *connective*, which may be either continuous with the filament or articulated with it. It consists of parenchyma, in which the spiral vessels of the filament terminate. From the connective a partition or *septum* extends across each antherine loculus, dividing it either partially or completely. The septum sometimes reaches the suture When the filament is continuous with the connective, and is prolonged so that the anther-lobes appear to be united to it throughout their whole length, and lie in apposition to it and on both sides of it, the anther is said to be *adnate* or *adherent*; when the filament ends at the base of the anther, then the latter is *innate* or *erect*. In these cases the anther is to a greater or less degree fixed. When, however, the attachment is very narrow, and an articulation exists, the anthers are movable, and are easily turned by the wind. This is well seen in what are called *versatile* anthers, as in Tritonia, Grasses, &c. (fig. 212), where the filament is attached only to the middle of the connective; and it may occur also in cases where it is attached to the apex, as in pendulous anthers. The connective may unite the anther-lobes completely, or only partially. It is sometimes very short, and is reduced to a mere point, so that the lobes are separate or free. At other times it is prolonged upwards beyond the lobes, assuming various forms, as in Acalypha, and Nerium Oleander; or it is extended backwards and downwards, as in Violet (fig. 221), and Ticorea febrifuga. In Salvia officinalis the connective is attached to the filament in a horizontal manner, so as to separate the two anther-lobes, and then it is called *distractile* (fig. 222); one of the lobes only being perfect or fertile, containing pollen, the other imperfectly developed and sterile. In Stachys the connective is expanded laterally, so as to unite the bases of the antherine lobes, and bring them into a horizontal line.

The opening of the anthers to discharge their contents is denominated *dehiscence*. This takes place either by clefts, by hinges, or by pores. When the anther-lobes are erect, the cleft takes place lengthwise along the line of the suture, constituting *longitudinal dehiscence* (fig. 175). At other times the slit takes place in a horizontal manner, from the connective to the side, as in Alchemilla arvensis (fig. 223) and in Lemna; the dehiscence is then *transverse*. When the anther-lobes are rendered horizontal by the enlargement of the connective, then what is really longitudinal dehiscence may appear to be transverse. In other cases, when the lobes are united at the base, the fissure in each of them may be continuous, and the two lobes may appear as one. The cleft does not always proceed the whole length of the anther-lobe at once, but often for a time it extends only partially. In other instances the opening is confined to the base or apex, each loculament opening by a single pore, as in Pyrola, Tetratheca juncea, Rhododendron, Vaccinium, and Solanum (fig. 224), where there are Antherine dehiscence.

Fig. 225.—The stamen of the Barberry (*Berberis vulgaris*), showing one of the valves of the anther *v*, curved upwards, bearing the pollen on its inner surface.

two, and Poranthera, where there are four; whilst in the Mistleto the anther has numerous pores for the discharge of the pollen. Another mode of dehiscence is called

hinged. In the Barberry (fig. 225) each lobe opens by a valve on the outer side of the suture, separately rolling up from base to apex; in some of the Laurel tribe there are two such valves for each lobe, or four in all. This may be called a combination of transverse and hinged dehiscence. In some Guttiferæ, as Hebradendron cambogioides (the Ceylon Gamboge plant), the anther opens by a lid separating from the apex; this is called *circumscissile* dehiscence.

The anthers dehisce at different periods during the process of flowering; sometimes in the bud, but more commonly when the pistil is fully developed, and the flower is expanded. They either dehisce simultaneously or in succession. In the latter case individual stamens may move in succession towards the pistil and discharge their contents, as in Parnassia palustris, or the outer or the inner stamens may first dehisce, following thus a centripetal or centrifugal order. The anthers are called *introrse* or *anticæ*, when they dehisce by the surface next to the centre of the flower; they are *extrorse*, or *posticæ*, when they dehisce by the outer surface; when they dehisce by the sides, as in Iris and some grasses, they are *laterally* dehiscent. Sometimes, from their versatile nature, anthers originally introrse become extrorse, as in the Passion-flower and Oxalis.

The usual colour of anthers is yellow, but they present a great variety in this respect. They are red in the Peach, dark purple in the Poppy and Tulip, orange in Eschscholtzia, &c. The colour and appearance of the anthers often change after they have discharged their functions.

Stamens occasionally become sterile by the degeneration or non-development of the anthers. Such stamens receive the name of *staminodia*, or rudimentary stamens. In Scrophularia the fifth stamen appears in the form of a scale; and in many Pentstemons it is reduced to a filament with hairs or a shrivelled membrane at the apex. In other cases, as in double flowers, the stamens are converted into petals; this is also probably the case with such plants as Mesembryanthemum, where there is a multiplication of petals in several rows. Sometimes, as in Canna, one of the anther-lobes becomes abortive, and a petaloid appendage is produced. Stamens vary in length as regards the corolla. Some are enclosed within the tube of the flower, as in Cinchona, and are called *included;* others are *exserted*, or extend beyond the flower, as in Littorella, Plantago, and Exostemma. Sometimes the stamens in the early state of the flower project beyond the petals, and in the progress of growth become included, as in Geranium striatum. Stamens also vary in their relative lengths as respects each other. When there is more than one row or whorl in a flower, those on the outside are sometimes longest, as in many Rosaceæ; at other times those in the interior are longest, as in Luhea. When the stamens are in two rows, those opposite the petals are usually shorter than those which alternate with the petals. It sometimes happens that a single stamen is longer than all the rest. A definite relation, as regards number, sometimes exists between the long and the short stamens. Thus, in some flowers the stamens are *didynamous*, having only four out of five stamens developed, and the two corresponding to the upper part of the flower longer than the two lateral ones. This occurs in Labiatæ and Scrophulariaceæ

Plate XI. (fig. 226). Again, in other cases, there are six stamens, whereof four long ones are arranged in pairs opposite to each other, and alternate with two isolated short ones (fig. 227), giving rise to *tetradynamous* flowers, as in Cruciferæ. Stamens, as regards their direction, may be erect, turned inwards, outwards, or to one side. In the last-mentioned case they are called *declinate*, as in Amaryllis, Horse-chestnut, and Fraxinella.

The *pollen* or powdery matter contained in the anther consists of small cells developed in the interior of other cells. These are produced in the large thick-walled mother Pollen.

cells or pollen utricles, formed in the interior of the pollen-sacs of the young anther. These mother-cells are either separated from one another and float in the granular fluid which fills up the cavity of the pollen-sac, or are not so isolated. A division takes place, by which four cells are formed in each, the exact mode of division differing in Dicotyledons and Monocotyledons. These cells are the pollen-cells or grains. They increase in size and acquire a cell-wall, which becomes differentiated into an outer cuticular layer, or *extine*, and an inner layer, or *intine*. Then the walls of the mother-cells are absorbed, and the pollen-grains float freely in the fluid of the pollen-sacs, which gradually disappears, and the mature grains form a powdery mass within the anther. They then either remain united in fours, or multiples of four, as in some Acacias, Periploca græca, and Inga anomala, or separate into individual grains, which by degrees become mature pollen. Occasionally the membrane of the pollen-cell is not completely absorbed, and traces of it are detected in a viscous matter surrounding the pollen-grains, as in Onagraceæ. In Orchidaceous plants the pollen-grains are united into masses, or *pollinia* (fig. 228), by means of viscid matter.

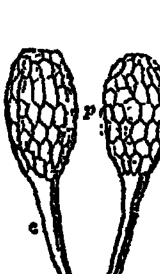

Fig. 228.

Fig. 230.

FIG. 228.—Pollinia, or pollen-masses, separated from the point above the stigma, with their retinacula or viscid matter attaching them at the base. The pollen masses *p* are supported on stalks or caudicles *c*. These masses are easily detached by the agency of insects.

FIG. 229.—Pistil of Asclepias, *a*, with pollen-masses, *p* adhering to the stigma *s*. *b*, pollen-masses, removed from the stigma, united by a gland-like body.

FIG. 230.—Stamen of Asclepias, showing filament *f*. anther *a*, and appendage *p*.

In Orchids each of the pollen-masses has a prolongation or stalk, called a *caudicle*, which adheres to a prolongation at the base of the anther, called *rostellum*, by means of a viscous gland, called *retinaculum*. The gland is either naked or covered. The term *clinandrium* is sometimes applied to the part of the column in Orchids where the

stamens are situated. In some Orchids, as Cypripedium, the pollen has its ordinary character of separate grains. The number of pollinia varies; thus, in Orchis there are usually two, in Cattleya four, and in Lælia eight. The two pollinia in Orchis Morio contain each about 200 secondary smaller masses. These small masses, when bruised, divide into grains which are united in fours. In Asclepiadaceæ the pollinia are usually united in pairs (fig. 229), belonging to two contiguous antherine cavities,—each pollen-mass having a caudicular appendage, ending in a common gland, by means of which they are attached to a process of the stigma. The pollinia are also provided with an appendicular staminal covering (fig. 230).

When mature, the pollen-grain is a cellular body having an external covering, *extine*, and an internal, *intine*. Fritzsche states that he has detected, in some cases, other two coverings, which he calls *intextine* and *exintine*. They occur between the extine and intine, and are probably formed by foldings of these membranes. In some aquatics, as Zostera marina, Zannichellia pedunculata, Naias minor, &c., only one covering exists, and that is said to be the intine. The extine is a firm membrane, which defines the figure of the pollen-grain, and gives colour to it. It is either smooth, or covered with numerous projections (fig. 231), granules, points, minute hairs, or crested reticulations. The colour is generally yellow, and the surface is often covered with a viscid or oily matter. The intine is uniform in different kinds of pollen, thin and transparent, and possesses great power of extension.

Pollen-grains vary from $\frac{1}{300}$ to $\frac{1}{100}$ of an inch or less in diameter. Their forms are various. The most common form of grain is ellipsoidal, more or less narrow at the extremities, which are called its *poles*, in contradistinction to a line equidistant from the extremities, and which is its equator. Pollen-grains are also spherical; cylindrical and curved, as in Tradescantia virginica; polyhedral in Dipsacaceæ and Compositæ; nearly triangular in Proteaceæ and Onagraceæ (fig. 232). The surface of the pollen-grain is either uniform and homogeneous, or it is marked by

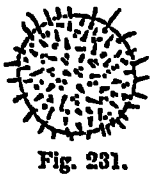

Fig. 231.

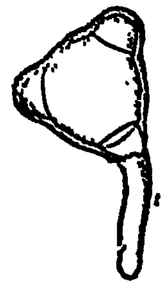

Fig. 232

Fig. 234.

FIG. 231.—Ripe round pollen of Hollyhock (*Althæa*), with its extine covered with prominent points.
FIG. 232.—Triangular pollen of Evening Primrose (*Œnothera*), with one pollen tube, *t*, protruded. This tube is formed by the intine, which is also seen projecting at the other angles.
FIG. 233.—Ripe rounded pollen of Cherry (*Cerasus*), discharging its fovilla through a tubular opening formed by the intine. There are other two points at which the intine is seen protruding.
FIG. 234.—Male flower of Pellitory (*Parietaria officinalis*), having four stamens with incurved elastic filaments, and an abortive pistil in the centre. When the perianth expands, the filaments are thrown out with force, so as to scatter the pollen on the female flowers in the vicinity.

folds dipping in towards the centre, and formed by thinnings of the membrane. In Monocotyledonous plants there is usually a single fold; in Dicotyledons, often three. Two, four, six, and even twelve folds are also met with. There are also rounded portions of the membrane or points of perforation or pores visible in the pollen-grain. These vary in number from one to fifty. In Monocotyledons, as in Grasses, there is often only one, while in Dicotyledons they number from three upwards. When numerous, these points are either scattered irregularly, or in a regular order, frequently forming a circle round the equatorial surface. Sometimes at the place where they exist, the outer membrane, in place of being thin and transparent, is separated in the form of a lid, thus becoming *operculate*, as in the Passion-flower and Gourd. Grains of pollen have sometimes both folds and pores. Within the pollen-grain a granular semifluid matter called *fovilla* is contained, along with some oily particles, and occasionally starch. The fovilla contains small spherical granules, sometimes the $\frac{1}{30000}$ of an inch in diameter, and large ellipsoidal or elongated corpuscles, which exhibit molecular movements under the microscope. The application of moisture affects very markedly the pollen-grain, causing it to swell up by endosmose. If the moisture be long applied the distension becomes so great as to rupture the extine irregularly if it is homogeneous, or to cause projections and final rupture at the folds or pores when they exist. The intine, from its distensibility, is not so liable to rupture; it is often forced through the ruptured extine, or through the pores, in the form of small sac-like projections. The internal membrane ultimately gives way, and allows the granular fovilla to escape (fig. 233). If the fluid is applied only to one side of the pollen-grain, as when the pollen is applied to the pistil, the distension goes on more slowly, and the intine is prolonged outwards like a hernia, and forms an elongated tube called a *pollen-tube* (fig. 232). This tube, at its base, is often covered by the ruptured extine, and it contains in its interior fovilla-granules. The number of pollen-tubes which may be produced depends on the number of pores. In some pollinia the number of tubes which are formed is enormous. Thus, it has been calculated that two pollen-masses of Orchis Morio may give out 120,000 tubes.

When the pollen-grains are ripe, the anther dehisces (figs. 175, 223), and the pollen is shed. In order that fertilization may be effected the pollen must be conveyed to the female organ of reproduction. This process, termed *pollination*, is promoted in various ways,—the whole form and structure of the flower having relation to the process. In some plants, as Kalmia and Pellitory (fig. 234), the mere elasticity of the filaments is sufficient to effect this; in other plants pollination is effected by the wind, as in Coniferæ, and in such cases enormous quantities of pollen are produced. These plants are *anemophilous*. But the common agents for pollination are insects. To allure and attract them to visit the flower the odoriferous secretions and gay colours are developed, and the position and complicated structure of the parts of the flower are adapted to the perfect performance of the process. It is rare in hermaphrodite flowers for self-fertilization to occur, and the various forms of dichogamy, dimorphism, and trimorphism are fitted to prevent this. Pollination.

Under the term *disk* is included every structure intervening between the stamens and the pistil. It was to such structures that the name of *nectary* was applied by old authors. It presents great varieties of form, such as a ring, scales, glands, hairs, petaloid appendages, &c., and in the progress of growth it often contains saccharine matter, thus becoming truly nectariferous. The disk is frequently formed by degeneration or transformation of the staminal row. It may consist of processes rising from the torus, alternating with the stamens, and thus representing an abortive whorl; or its parts may be oppo- Disk.

site to the stamens, as in Crassula rubens (fig. 172). In some flowers, as Jatropha Curcas, in which the stamens are not developed, their place is occupied by glandular bodies forming the disk. In Gesneraceæ and Cruciferæ the disk consists of tooth-like scales at the base of the stamens (fig. 227). The parts composing the disk sometimes unite and form a glandular ring, as in the Orange; or they form a dark-red lamina covering the pistil, as in Pæonia Moutan (fig. 235); or a waxy lining of the calyx tube or hollow receptacle, as in the Rose; or a swelling at the top of the ovary, as in Umbelliferæ, in which the disk is said to be epigynous. The enlarged torus covering the ovary in Nymphæa and Nelumbium may be regarded as a form of disk.

2. *Male Organs in Cryptogams.*

Male organs. Cryptogams.

Sexual organs have not as yet been demonstrated in all Cryptogamic plants; but in most of them certain structures representing the male organs have been found. These are termed *Antheridia* or *Pollinodia* (figs. 236, 250). They are closed sacs of various forms,—rounded, ovate, oblong, clavate, flask-like, &c.,—developed from various parts of the plants, and composed either of one or of many cells enclosing a single central cell. In the interior of this organ small cells (fig. 236, *c*) are formed of varying shape, containing in their interior peculiar bodies, termed *antherozoids, spermatozoids*, or *phytozoa* (fig. 237). These are in most cases filamentous spirally coiled cells, frequently with *cilia*

Fig. 239.—Antheridium of a Sea-weed (*Fucus serratus*), still containing two phytozoa in the sac. To the broad part of the phytozoa two vibratile cilia are attached.
Fig. 240.—Axis of Chara, with branches from the axil of which arises the nucule *n*; below them is the globule *g*.
Fig. 241.—Globule of Chara, being a rounded body with eight radiating valves externally, and filaments containing phytozoary cells internally.

attached, by means of which they move rapidly through the water. In some cases there are no cilia, as in the Algal group of Florideæ; and the antherozoids of all Algæ differ from those of other Cryptogams in never being filamentous, but short and more or less rounded. The amount of twisting of the antherozoid varies; in some Rhizocarps there are as many as a dozen coils. Antheridia of this kind have been demonstrated in all vascular Cryptogams, but only in some Thallogens have such structures been seen.

In Characeæ, however, the antheridium, which is here termed *globule* (fig. 240), has a peculiar structure, differing from all other Cryptogams. It is a globular case, formed by eight flat cells, of which four are quadrangular and four are triangular; and these are folded at the margins so that the edges of contiguous plates dovetail (fig. 241). These are termed *shields*. Into the cavity of the globule the terminal cell of the stalk supporting it projects. From the centre of each shield projects on the inner surface a large oblong cell or *manubrium*, which in turn bears at its apex a roundish cell termed the *head*. From each head-cell six secondary head-cells project, from each of which pass off four slender separate filaments (fig. 242) containing antherozoids. When mature the antheridium is ruptured, and the mother-cells of the antherozoid escape and discharge the antherozoids into the surrounding medium which is always water—fertilization only being effected in water, by which the antherozoids are carried to the female organ. In some cases, however, among Thallogens the antheridium actually penetrates into the female organ.

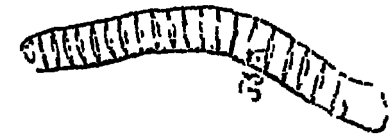

Fig. 242.

Partitioned filament of Chara, consisting of a series of cellules containing phytozoa, one of which is seen escaping in the form of a spiral thread.

Antheridia are produced on various parts of plants. Where they have been found amongst Thallogens, they arise from definite portions of the cellular thallus. In thalloid Hepaticæ they may be sunk in the substance of the thallus, or they may be imbedded in the upper surface of a peltate stalked disk rising from the thallus, as in Marchantia (figs. 243, 244). In Mosses they may be seated within the same whorl of leaves or perichætium as the female organs, or they may be separate and surrounded by a *perigone*; but they are always formed upon the leaf-bearing axis, either terminal or lateral. In Ferns and Equisetum they are produced on the surface—usually the lower surface—of a cellular flattened expansion, termed a *prothallus* (figs. 245, 250), in close proximity to the female organs. In Characeæ they always arise from the termination of one of the whorled leaflets.

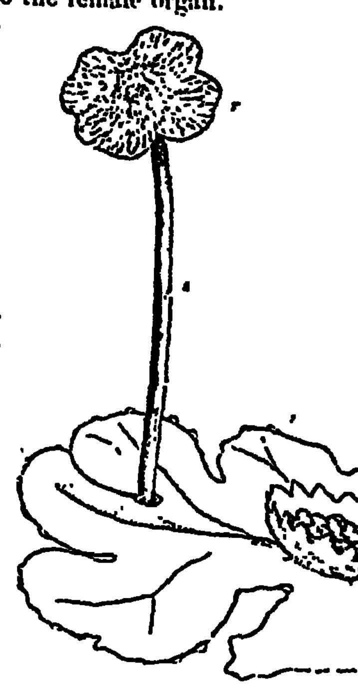

Fig. 243.

A species of Liverwort (*Marchantia polymorpha*) with its green thallus *t*, bearing a cup-like body *g*, in which minute cells or free buds are seen, and a stalked receptacle *s, r*. In the substance of the disk-like receptacle *r* cells are produced containing phytozoa. These are considered antheridia.

In some Lycopodiaceæ no antheridia have as yet been found; but in Selaginella, Isoetes, and in the Rhizocarpeæ, hollow sacs, termed *microsporangia* (figs. 246, 248), are produced in the axil of certain leaves of the

plant, in which small cells, *microspores* (fig. 249), are found, each consisting of an outer covering or *exospore*, and an inner or *endospore*. Within those microspores (the manner varying in different genera) smaller cells are formed, which are the mother-cells of the antherozoids. In this

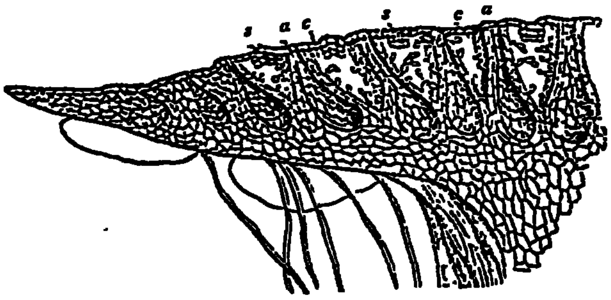

Fig. 244.

They communicate with the upper surface, and their contents are discharged through it. Between the antheridia there are air cavities *c*, *c*, connected with stomata *s*, *s*.

development of Lycopodiaceæ we have parts which are analogous to those of the stamens in Phanerogams. The microsporangium evidently corresponds to the pollen-sac, and the microspores are the equivalents of the pollen-grains,—the forms seen in such Gymnosperms as Cycadaceæ being the link connecting them with the highest forms.

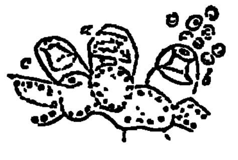
3. *Female Organs in Phanerogams.*

The pistil or *gynœcium* occupies the centre or axis of the flower, and is surrounded by the stamens and floral envelopes when these are present. It constitutes the innermost whorl, and is the female organ of the plant, which after The pistil.
flowering is changed into the fruit, and contains the seeds. It consists essentially of two parts, a basal portion forming a chamber, the *ovary* or *germen*, containing ovules or young seeds attached to a part called the *placenta*, and an upper portion, the *stigma*, a cellular secreting body, which is either seated on the ovary, and is then called *sessile*, as in the Tulip and Poppy, or is elevated on a stalk called the Plate I.
style, interposed between the ovary and stigma. The style



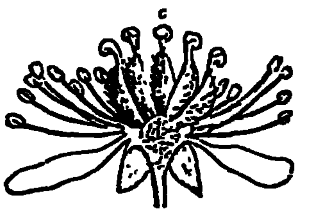


Fig. 251. Fig. 252. Fig. 253.

Fig. 251.—Folded carpellary leaf of the double-flowering Cherry. In place of fruit the plant produces leaves.

Fig. 252.—Vertical section of the flower of Meadow-sweet (*Spiræa*). The pistil is apocarpous, consisting of several distinct carpels *c*, each with ovary, style, and stigma. The stamens are indefinite, and are inserted into the calyx.

Fig. 253.—Pistil of Broom, consisting of ovary *o*, style *s*, and stigma *t*. It is formed by a single carpel. The terms pistil and carpel are here synonymous.

is not necessary for the perfection of the pistil. Like the Plate V.
other organs, the pistil consists of one or more modified leaves, which in this instance are called *carpels*. When a pistil consists of a single carpel it is *simple* or monocarpellary (fig. 253), a state usually depending on the non-development of other carpels. When it is composed of several carpels, more or less united, it is *compound* or polycarpellary. In the first-mentioned case the terms carpel and pistil are synonymous. Each carpel has its own ovary, style (when present), and stigma, and is formed by a folded leaf, the upper surface of which is turned inwards towards the axis, and the lower outwards, while from its margins are developed one or more buds called *ovules*. That this is the true nature of the pistil may be seen by examining the flower of the double-flowering Cherry. In it no fruit is produced, and the pistil consists of sessile leaves (fig. 251), the limb of each being green and folded, with a narrow prolongation upwards, as if from the midrib, and ending in a thickened portion. The ovary then represents the limb or lamina of the leaf, and is composed of cellular tissue with fibro-vascular bundles, and an epidermal covering. The cellular tissue, or parenchyma, often becomes much developed, as will be seen particularly when fleshy fruits are considered. The outer epidermis corresponds to the lower side of the leaf, exhibiting stomata, and sometimes hairs; the inner surface represents the upper side of the leaf, being usually very delicate and pale, and forming a layer called sometimes *epithelium*, which does not exhibit stomata. The vascular bundles correspond with the veins of the leaf, and consist of spiral, annular, and other vessels. In Cycas the carpels Plate XV.
are ordinary leaves, with ovules upon their margin.

A pistil is usually formed by more than one carpel. The carpels may be arranged like leaves, either at the same or nearly the same height in a verticil, or at different heights in a spiral cycle. When they remain separate and distinct, thus showing at once the composition of the pistil, as in Caltha, Ranunculus, Hellebore, and Spiræa (fig. 252), the term *apocarpous* is applied. Thus, in Crassula rubens (fig. 172) the pistil consists of five verticillate carpels *c*, alternating with the stamens *e*. In the Tulip-tree and Ranunculus (fig. 254) the separate carpels are numerous and are arranged in a spiral cycle upon an elongated axis or receptacle. In the Raspberry the carpels are on a conical

receptacle; in the Strawberry, on a swollen succulent one (fig. 154); and in the Rose (fig. 155), on a hollow one. When the fruit consists of several rows of carpels, the innermost have their margins directed to the centre, while the margins of the outer rows are arranged on the back of the inner ones. When the carpels are united, as in the Pear, Arbutus, and Chickweed, the pistil becomes *syncarpous*. The number of carpels in an apocarpous pistil, or the number of separate styles in a syncarpous one, is indicated in the following way:—

A flower with a simple pistil or 1 style	is Monogynous.
2 separate carpels or 2 separate styles	is Digynous.
3 carpels or 3 separate styles	is Trigynous.
4 carpels or 4 separate styles	is Tetragynous.
5 carpels or 5 separate styles	is Pentagynous.
6 carpels or 6 separate styles	is Hexagynous.
7 carpels or 7 separate styles	is Heptagynous.
8 carpels or 8 separate styles	is Octogynous.
9 carpels or 9 separate styles	is Enneagynous.
10 carpels or 10 separate styles	is Decagynous.
12 carpels or 12 separate styles	is Dodecagynous.
a greater number of carpels or styles	is Polygynous.

The union in a syncarpous pistil is not always complete; it may take place by the ovaries alone, while the styles and stigmata remain free, the pistil being then *gamogastrous* (fig. 255), and in this case, when the ovaries form apparently a single body, the organ receives the name of *compound* ovary; or the union may take place by the ovaries and styles, while the stigmata are *disunited*; or by the stigmata and the summit of the style only. Various intermediate states exist, such as *partial union* of the ovaries, as in the Rue, where they coalesce at their base; Plate III. and partial *union of the styles*, as in Malvaceæ. The union is usually most complete at the base; but in Labiatæ the styles are united throughout their length, and in Apocynaceæ and Asclepiadaceæ the stigmata only. When the union is incomplete, the number of the parts of a compound pistil may be determined by the number of styles and *stigmata*; when complete, the external venation, the grooves on the surface, and the internal divisions of the ovary, indicate the number. The changes which take place in the pistil by adhesion, degeneration, and abortion, are frequently so great as to obscure its composition, and to lead to anomalies.

Fig. 254.

Fig. 255.

Fig. 256.—[illegible] (*[illegible]*) laid open. It consists of a single [illegible] ov, which are attached to the placenta *pl*, by means of umbilical cords (funiculi) *f*. The [illegible] the outer, *ep*, corresponding to the upper epidermis [illegible] small amount of cellular tissue [illegible] is persistent. The style [illegible]

sessile leaves, but sometimes they are petiolate, and then are elevated above the external whorls. This elevation of the pistil may in general, however, be traced to an elongation of the axis itself, in such a way that the carpels, in place of being dispersed over it, arise only from its summit, and the pistil becomes *stipitate*, or supported on a stalk called a *gynophore* or *thecaphore*, as in the Passion-flower and Dictamnus (fig. 177). Sometimes the axis is produced beyond the ovaries, and the styles become united to it, as in Geraniaceæ (fig. 152) and Umbelliferæ. In this case the prolongation is called a *carpophore*. A Plate VII monstrosity often occurs in the Rose (fig. 145) by which the axis is prolonged, and bears the carpels *f* in the form of alternate leaves.

The ovary contains the ovules. These are attached to The the *placenta*. This, sometimes called the *trophosperm*, placenta. consists of a mass of cellular tissue, through which the vessels pass to the ovule. The placenta is usually formed on *the edges of the carpellary leaf (fig. 256), and is then said* to be of the *marginal* type. In many cases, however, the placentas are formations from the axis, and are not connected with the carpellary leaves; they are then said to be *axile*. Some restrict the term placenta to the point of attachment of a single ovule, and call the union of placentas, bearing several ovules, *placentaries* or *pistillary cords*. In marginal placentation the part of the carpel bearing the placenta is the *inner* or *ventral suture*, corresponding to the margin of the folded carpellary leaf, while the *outer* or *dorsal suture* corresponds to the midrib of the carpellary leaf. As the placenta is formed on each margin of the carpel it is essentially *double*. This is seen in cases where the margins of the carpel do not unite, but remain separate, and consequently two placentas are formed in place of one. When the pistil is formed by one carpel the inner margins unite in the axis, and form usually a common marginal placenta. This placenta may extend along the whole margin of the ovary as far as the base of the style (fig. 256), or it may be confined to the base or apex only. When the pistil is composed of several separate carpels, or, in other words, is apocarpous, there are generally separate placentas at each of their margins. In a syncarpous pistil, on the other hand, the carpels are so united that the edges of each of the contiguous ones, by their union, form a *septum*, or *dissepiment*, and the number of these septa consequently indicates the number of carpels in the compound pistil (fig. 257). It is obvious then that each dissepiment

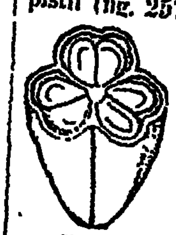

Fig. 257.

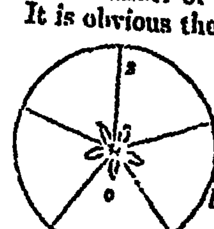

Fig. 258.

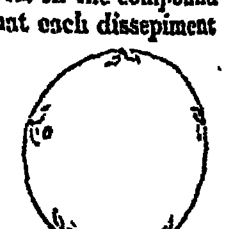

Fig. 259.

Fig. 257.—Ovary or lower part of the pistil of the Lily (*Lilium*), cut transversely. There are three loculaments, indicating the union of three carpels, and the ovary is said to be trilocular. The divisions in the ovary, called septa or dissepiments, are *formed* by the sides of the carpellary leaves. Each septum is double, and the number of septa corresponds with the number of the carpels. The ovules are placed collaterally, in pairs, in each loculament, and are attached to a central placenta, formed by the union of the three ventral sutures.

Fig. 258.—Diagrammatic section *of* a quinquelocular or pentathecal ovary, composed of five carpels, the edges of which are folded inwards, and meet in the centre. The ovules o are attached to a central placenta, formed by the union of the five ventral sutures. The five partitions, septa, or dissepiments, s, are composed of the *two sides of* contiguous carpels. Dorsal suture, *l*.

Fig. 259.—Diagrammatic section of a quinquelocular ovary, in which the edges of the carpels, bearing the placentas and ovules o, are not folded inwards. The placentas are parietal, and the ovules appear sessile on the walls of the ovary. The compound ovary is unilocular, and the edges of its carpels are applied to each other in a valvular manner.

is formed by a double wall or two laminæ; that the presence of a septum implies the presence of more than one carpel; and that, when carpels are placed side by side, true dissepiments must be vertical, and not horizontal. When the dissepiments extend to the centre or axis, the ovary is

divided into cavities, *cells*, or *loculaments*, and it may be *bilocular*, *trilocular* (fig. 257), *quadrilocular*, *quinqulocular*, or *multilocular*, according as it is formed by two, three, four, five, or many carpels, each carpel corresponding to a single cell or loculament. In these cases the marginal placentas meet in the axis, and unite so as to form a single *central* one (figs. 257, 258), and the ovules appear in the central angle of the loculi, as in Canna, Lily (fig. 257). The number of loculaments is equal to that of the dissepiments. When the carpels in a syncarpous pistil do not fold inwards completely so as to meet in the centre, but only partially, so that the dissepiments appear as projections on the walls of the ovary, then the ovary is *unilocular* (fig. 260), and the placentas are *parietal*, as in Viola (fig. 261). In

FIG. 260.—Diagrammatic section of a quinquelocular ovary, in which the septa *s* proceed inwards for a certain length, bearing the placentas and ovules *o*. In this case the ovary is unilocular, and the placentas are parietal. Dorsum, *l*.
FIG. 261.—Pistil of *Viola tricolor*, or Pansy. 1. Vertical section to show the ovules *o*, attached to the parietes. Two rows of ovules are seen, one in front, and the other in profile; *p*, a thickened line on the walls forming the placenta; *c*, calyx; *d*, ovary; *s*, hooded stigma terminating the short style. 2. Horizontal section of the same: *p*, placenta; *o*, ovules; *s*, suture.

these instances the placentas may be formed at the margin of the united contiguous leaves, so as to appear single, or the margins may not be united, each developing a placenta. Frequently the margins of the carpels, which fold in to the centre, split there into two lamellæ, each of which is curved outwards and projects into the loculament, dilating at the end into a placenta. This is well seen in Cucurbitaceæ (fig. 262), Pyrola, &c. From this it will be seen that dissepiments are opposite to placentas formed by the union of the margins of two contiguous carpels, but alternate with those formed by the margins of the same carpel. The carpellary leaves may fold inwards very slightly, or they may be applied in a valvate manner, merely touching at their margins, the placentas then being parietal (fig. 259), and appearing as lines or thickenings

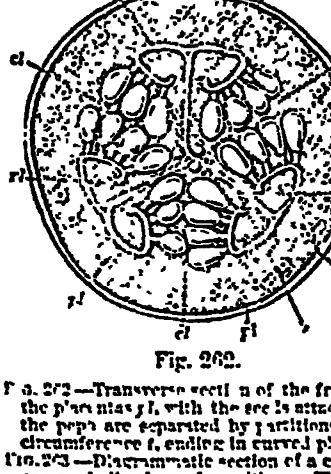

Fig. 262.

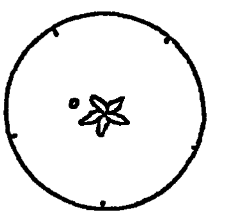

Fig. 263.

FIG. 262.—Transverse section of the fruit of the Melon (*Cucumis Melo*), showing the placentas *pl*, with the ovules attached to them. The three carpels forming the pepo are separated by partitions *cl*. From the centre, processes *s*, go to circumference *f*, ending in curved placentaries bearing the ovules.
FIG. 263.—Diagrammatic section of a compound unilocular ovary, in which there are no indications of partitions. The ovules *o* are attached to a free central placenta, which has no connection with the walls of the ovary.

along the walls. Cases occur, however, in which the placentas are not connected with the walls of the ovary, and form what is called a *free central placenta* (fig. 263). This is seen in many of the Caryophyllaceæ and Primulaceæ (figs. 264, 265). In Caryophyllaceæ, however, while the placenta is free in the centre, there are often traces found at the base of the ovary of the remains of septa, as if rupture had taken place, and, in rare instances, ovules are found on the margins of the carpels. But in Primulaceæ, Myrsinaceæ, and Santalaceæ, no vestiges of septa or marginal ovules can be perceived at any period of growth; the placenta is always free, and rises in the centre of the ovary, and the part uncovered by ovules gradually extends into the style. Free central placentation, therefore, has been accounted for in two ways; either by supposing that the placentas in the early state were formed on the margins of carpellary leaves, and that in the progress of development these leaves separated from them, leaving the placentas and ovules free in the centre; or by supposing that the placentas are not *marginal* but *axile* formations, produced by an elongation of the axis, the ovules being lateral buds, and the carpels verticillate leaves, united together around the axis. The first of these views would apply well to Caryophyllaceæ, the second to Primulaceæ. The latter case has also been explained, on the marginal hypothesis, by considering the placentas as formed from the carpels by a process of chorisis, and united together in the centre.

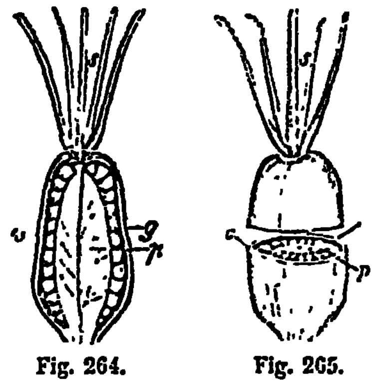

Fig. 264. Fig. 265.

FIG. 264.—Pistil of *Cerastium hirsutum* cut vertically. *o*, unilocular or monothecal ovary; *p*, free central placenta; *g*, ovules; *s*, styles.
FIG. 265.—The same cut horizontally, and the halves separated so as to show the interior of the cavity of the ovary *o*, with the free central placenta *p*, covered with ovules *g*.

Some consider the axile view of placentation as applicable to all cases, the axis in some instances remaining free and independent, at other times sending prolongations along the margins of the carpellary leaves, and thus forming the marginal placentas. Occasionally, divisions take place in ovaries which are not formed by the edges of contiguous carpels. These are called *spurious dissepiments*. They are often horizontal, and are then called *phragmata*, as in Cathartocarpus Fistula, where they consist of transverse cellular prolongations from the walls of the ovary, only developed after fertilization, and therefore more properly noticed under fruit. At other times they are vertical, as in Datura, where the ovary, in place of being two-celled, becomes four-celled; in Cruciferæ, where the prolongation of the placentas forms a *replum* or partition; in Astragalus and Thespesia, where the dorsal suture is folded inwards: in Oxytropis, where the ventral suture is folded inwards; and in Diplophractum, where the inner margin of the carpels is inflexed. In Cucurbitaceæ divisions are formed in the ovary apparently by peculiar projections inwards from curved parietal placentas. In some cases horizontal dissepiments are supposed to be formed by the union of carpels situated at different heights, so that the base of one becomes united to the apex of another. In such cases the divisions are true dissepiments formed by carpellary leaves. The anomalous divisions in the ovary of the Pomegranate have been thus explained.

The ovary is usually of a more or less spherical or curved form, sometimes smooth and uniform on its surface, at other times hairy and grooved. The grooves usually indicate the divisions between the carpels, and correspond to the dissepiments. The dorsal suture may be marked by a slight projection, or by a superficial groove. When the ovary is situated on the centre of the receptacle, free from the other whorls, so that its base is above the insertion of the stamens, it is

termed *superior*, as in Lychnis, Primula, and Geranium (fig. 215). When the margin of the receptacle is prolonged upwards, carrying with it the floral envelopes and staminal leaves, the basal portion of the ovary being formed by the receptacle, and the carpellary leaves alone closing in the apex, the ovary is *inferior*, as in Pomegranate, Apple, Pear, Gooseberry, and Fuchsia. In some plants, as many Saxifragaceæ, there are intermediate forms, in which the term *half-inferior* is applied to the ovary, whilst the floral whorls are *half-superior*.

The style. The *style* proceeds from the summit of the carpel, and may be looked upon as a prolongation of it in an upward direction (fig. 267). It is hence called *apicilar*. It consists not merely of the midrib but of the vascular and cellular tissue of the carpel, and when carefully examined is found to be traversed by a narrow canal, in which there are some loose projecting cells, a continuation of the placenta, constituting what is called conducting tissue, which ends in the stigma. This is particularly abundant when the pistil is ready for fertilization. In some cases, owing to more rapid growth of the dorsal side of the ovary, the style becomes *lateral* (fig. 266); this may so increase that the style appears to arise from near the base, as in the Strawberry, or from the base, as in Chrysobalanus Icaco, when it is called *basilar*. In all these cases the style still indicates the organic apex of the ovary, although it may not be the apparent apex. When in a compound pistil the style of each carpel is thus displaced, it appears as if the ovary were depressed in the centre, and the style rising from the depression in the midst of the carpels seems to come from the torus. Such a style is *gynobasic*, and is well seen in Boraginaceæ and Ochnaceæ. The form of the style is usually cylindrical, more or less filiform and simple; sometimes it is grooved on one side, at other times it is flat, thick, angular, compressed, and even petaloid, as in Iris and Canna. In Goodeniaceæ it ends in a cup-like expansion, enclosing the stigma. It may be smooth and covered with glands and hairs. These hairs occasionally aid in the application of the pollen to the stigma, and are called *collecting hairs*, as in Goldfussia, in Campanula, where they appear double and retractile, and also in Aster and other Compositæ. These hairs, during the upward development of the style, come into contact with the already

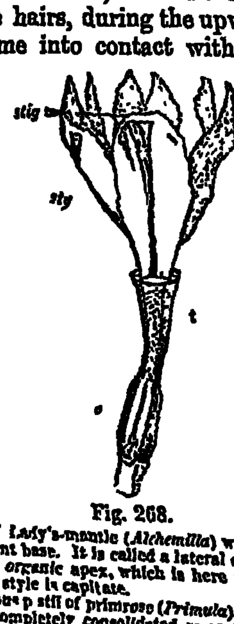

Fig. 268.

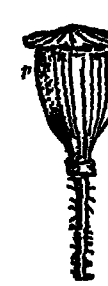

Fig. 269.

Fig. 266.—Uni-ovular carpel of Lady's-mantle (*Alchemilla*) with the style *s* arising laterally near the apparent base. It is called a lateral or semi-basilar style, although it arises from the *organic* apex, which is here turned round. The stigma at the summit of the style is capitate.
Fig. 267.—Compound or syncarpous pistil of primrose (*Primula*). The five carpels of which it is composed are completely consolidated so as to appear one. The ovaries *o*, the styles *t*, and stigmata *s*, are united. The flower is called monogynous, although in reality there are five parts of the pistil.
Fig. 268.—Gynæcium of the Flower-de-Luce (*Iris*), consisting of an ovary *o* adherent to the perianth, and a style *sty*, which divides into three petaloid segments bearing stigmas *stig*. The ovary is inferior, the perianth superior.
Fig. 269.—Capsule of Poppy, opening by pores *p*, under the radiating peltate stigma.

ripened pollen, and carry it up along with them, ready to be applied by insects to the mature stigma of other flowers. In Vicia and Lobelia the hairs frequently form a tuft below the stigma. The styles of a syncarpous pistil may be either separate or united; when separate, they alternate with the septa. When united completely, it is usual to call the style *simple* (fig. 267); when the union is partial, then the style is said to be *bifid*, *trifid*, *multifid*, according as it is two-cleft, three-cleft, many-cleft; or, to speak more correctly, according to the mode and extent of the union of two, three, or many styles. The style is said to be *bipartite*, *tripartite*, or *multipartite*, when the union of two, three, or many styles only extends a short way above the apex of the ovary. The style of a single carpel, or of each carpel of a compound pistil, may also be divided. Each division of the tricarpellary ovary of Jatropha Curcas has a *bifurcate* or forked style, and the ovary of Emblica officinalis has three styles, each of which is divided twice in a bifurcate manner, exhibiting thus a dichotomous division. The length of the style is determined by the relation which ought to subsist between the position of the stigma and that of the anthers, so as to allow the proper application of the pollen. In some cases the ovary passes insensibly into the style, as in Digitalis, in other instances there is a Plate XI marked transition from one to the other. The style may remain *persistent*, or it may fall off after fertilization is accomplished, and thus be *deciduous*.

The stigma. The *stigma* is the termination of the conducting tissue of the style, and is usually in direct communication with the placenta. It may, therefore, in most instances, be considered as the placental portion of the carpel, prolonged upwards. In Armeria, and some other plants, this connection with the placenta cannot be traced. The stigma consists of loose cellular tissue, and secretes a viscid matter which detains the pollen and causes it to protrude tubes. This secreting portion is, strictly speaking, the true stigma, but the name is generally applied to all the divisions of the style on which the stigmatic apparatus is situated. The stigma alternates with the dissepiments of a syncarpous pistil, or, in other words, corresponds with the back of the loculaments; but in some cases it would appear that half the stigma of one carpel unites with half that of the contiguous carpel, and thus the stigma is opposite the dissepiments, that is, alternates with the loculaments, as in the Poppy. If the stigma is viewed as essentially a prolongation of the placenta, then there is no necessary alternation between it and the placenta, both being formed by the margins of carpellary leaves, which in the one case are ovuliferous, in the other stigmatiferous. There is often a notch on one side of a stigma (as in some Rosaceæ), indicating apparently that it is a double organ like the placenta. To the division of a compound stigma the terms *bifid*, as in Labiatæ, Compositæ, *trifid*, as in Polemonium, &c., are applied, according to the number of the divisions. When the divisions are large, they are called *lobes*, and when flattened like bands, *lamellæ*; so that stigmas may be *bilobate*, *trilobate*, *bilamellar*, *trilamellar*, &c.

It has already been stated that the divisions of the stigma mark the number of carpels which are united together. A quinquefid or five-cleft stigma indicates five carpels, as in Campanula, although the other parts are united. In Bignoniaceæ, as well as in Scrophulariaceæ and Acanthaceæ, the two-lobed or bilamellar stigma indicates a bilocular ovary. Sometimes, however, as in the case of the styles, the stigma of a single carpel may divide. It is probable that in many instances what is called bifurcation of the style is only the division of the stigma. In Gramineæ and Compositæ there is a bifid stigma, and only one cavity in the ovary. This, however, may be probably traced to subsequent abortion in the ovary of one of the carpels. Its position may be terminal or lateral; either on one side of the style, *uni-*

lateral, as in Asimina, or on both sides, *bilateral*, as in Plantago. Occasionally, as in Tasmannia, it is prolonged along the inner surface of the style. In Iris it is situated on a cleft on the back of the petaloid divisions of the style (fig. 268). Some stigmata, as those of the Mimulus, present sensitive flattened laminæ, which close when touched. The stigma presents various forms. It may be globular, as in Mirabilis Jalapa; orbicular, as in Arbutus Andrachne; umbrella-like, as in Sarracenia, where, however, the proper stigmatic surface is beneath the angles of the large expansion of the apex of the style; ovoid, as in Fuchsia; hemispherical; polyhedral; radiating, as in
ı I. the Poppy (fig. 269), where the true stigmatic rays are attached to a sort of *peltate* or shield-like body, which may represent depressed or flattened styles; *cucullate*, *i.e.*, covered by a hood, in Calabar Bean, where it is situated on the apex of a declinate style, bearded (hairy) on its concave surface The lobes of a stigma may be flat and pointed, as in Mimulus and Bignonia, fleshy and blunt, smooth or granular, or they may be feathery, as in many Grasses (fig. 213). In Orchidaceæ the stigma is situated on the anterior surface of the column formed by the union of the styles and filaments,—the point where it occurs being called *gynizus*. In Asclepiadaceæ the stigmas are united to the face of the anthers, and along with them form a solid mass (fig. 229).

ıs- ıations istil. Transformations of the pistil are of frequent occurrence, and depend generally on abortion of a certain number of carpels, and on adhesions of various kinds. In the apocarpous pistils of Aconite, Nigella, Larkspur, and Pæony, we find on the same plant pistils composed of two, three, four, five, and six carpels. In some of the Brambles, all the carpels except one have been observed to disappear, thus making the fruit resemble that of the Plum. In the case of Leguminous plants there is usually only a single carpel, although the flower is pentamerous; this state has been traced to abortion of carpels, and the view is confirmed by finding plants in the same natural order with more than one carpel. Pistils of a succulent nature, such as those of the Sloe and Bird-cherry, sometimes assume the form of a pod, like that of the Pea. Occasionally stamens are changed into carpels, and at other times the carpels are transformed into stamens, and bear pollen.

ı ovule. The ovule is the body attached to the placenta, and destined to become the seed. Ovules are most usually produced on the margins of the carpellary leaves, but are also formed over the whole surface of the leaf, as in Cupressus. In other instances they rise from the floral axis itself, either as terminal buds, as in Polygonaceæ and Piperaceæ, or as lateral buds, as in Primulaceæ and Compositæ. The ovule is usually contained in an ovary, and all plants in which the ovule is so enclosed are termed *angiospermous;* but in Coniferæ and Cycadaceæ it is generally considered as having no proper ovarian covering, and is called *naked*, these orders being denominated *gymnospermous* The gymnospermal view is not adopted by all botanists. some maintaining that there is a true ovarian
ıto XV. covering In Cycas the altered leaf, upon the margin of which the ovule is produced, and the peltate scales, from which they are pendulous in Zamia, are regarded by all botanists as carpellary leaves But in the Coniferæ great discussion has arisen regarding the morphology of parts in many genera; some considering the scales at the base of the scaly bracts of the cone as a placental process growing from the bract. which is thus a carpellary leaf opened out and bearing a sessile ovule. the whole cone representing a single flower: while others. again. regard the scale as an ovular integument. and the ovule as being destitute of ovary. the outer scales being bracts. and the cone therefore being an inflorescence. The carpellary leaves are sometimes united in such a way as to leave an opening at the apex of the pistil, so that the ovules are exposed or *seminude*, as in Mignonette. In Leontice thalictroides (Blue Cohosh), species of Ophiopogon, Peliosanthes, and Stateria, the ovary ruptures immediately after flowering, and the ovules are exposed; and in species of Cuphea the placenta ultimately bursts through the ovary and corolla, and becomes erect, bearing the exposed ovules. The ovule is attached to the placenta either directly, when it is called *sessile*, or by means of a prolongation called a *funiculus*, *umbilical cord*, or *podosperm* (fig. 270*a*, *f*). This cord sometimes becomes much elongated after fertilization. The part by which the ovule is attached to the placenta or cord is its *base* or *hilum*, the opposite extremity being its *apex*. The latter is frequently turned round in such a way as to approach the base. The ovule is sometimes embedded in the placenta, as in Hydnora.

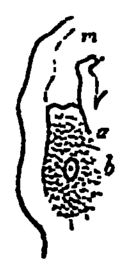

Fig. 272.

FIG. 270.—Young ovule of Celandine (*Chelidonium majus*) before its coverings are developed. It consists of the nucleus *n*, which at this stage of growth is naked. The base of the nucleus, where the nourishing vessels enter, is marked *ch*. This point is called the chalaza.

FIG. 270*a*.—The ovule of Polygonum, with its nucleus *n*, covered by the inner coat *s*, or the secundine, and the outer coat *p*, or the primine. The opening in the secundine, *end*, is called the endostome, that in the primine, *ex*, is the exostome. The point of the nucleus is seen projecting at the foramen. The end by which the ovule is attached to the placenta is marked *f*.

FIG. 271.—Orthotropous or orthotropal ovule of Polygonum, showing the embryo-sac *s*, in the nucleus *n*, the different ovular coverings, the base of the nucleus or chalaza *ch*, and the apex of the ovule with its foramen *m*.

FIG. 272.—Vertical section of the ovule of the Austrian Pine (*Pinus austriaca*), showing the nucleus *a*, consisting of delicate cellular tissue containing deep in its substance an embryo-sac *b*, formed before impregnation by the coalescence of a vertical series of a few cells. The micropyle *m* is very wide, and through it the pollen-grains come into contact with the summit of the nucleus, into the substance of which they send their tubes.

The ovule appears at first as a small cellular projection from the placenta. The cells multiply until they assume a more or less enlarged ovate form, constituting what has been called the *nucleus* (fig. 270, *n*), or central cellular mass of the ovule. The nucleus may remain naked, and alone form the ovule, as in Balanophoraceæ, Santalaceæ, &c.; but in most plants it becomes surrounded by certain coverings or integuments during its development. These appear first in the form of cellular rings at the base of the nucleus, which gradually spread over its surface. In some cases only one covering is formed, especially amongst gamopetalous Dicotyledons, as in Compositæ, Campanulaceæ, also in Walnut, &c. But usually besides the single covering (fig. 270*a*, *s*) another is developed subsequently (fig. 270*a*, *p*), which gradually extends over that first formed, and ultimately covers it completely, except at the apex. There are thus two integuments to the nucleus, an

of the micropyle depends on the development of the nucleus, as well as on the thickness of the integuments. Where the integument is very thick and the nucleus small, the micropyle is a long canal, as in Hippuris; but more usually the nucleus is large, and the integuments reduced to a few layers of cells, and in this case the micropyle is correspondingly reduced. The nucleus alters in the progress of growth so as to be prepared for the development of the embryo in its interior. A single cell of the nucleus near its centre enlarges greatly until it forms a hollow cavity surrounded by the smaller cells of the nucleus. This cavity is the *embryo-sac* (fig. 274, *s*), and the protoplasmic contents have been termed the *amnios*. This embryo-sac increases in size, gradually supplanting the surrounding cellular tissue of the nucleus until it remains surrounded only by a thin layer of it; or it may actually extend at the apex beyond it, as in Phaseolus and Alsine media; or it may pass into the micropyle, as in Santalum. In Gymnosperms it usually remains deep in the nucleus and surrounded by a thick mass of cellular tissue (fig. 272). In Veronica, Euphrasia, and many Labiatæ, the neck of the embryo-sac becomes elongated and swollen, and from it are developed certain vermiform or filamentous appendages, which are probably connected with the nutrition of the embryo. In some cases more than one embryo-sac is formed. This occurs in some gymnospermous plants, as the Yew, and it is also seen in Cruciferæ. In the Mistleto several sacs are formed, but it is doubtful whether in this case several ovules have not coalesced. Usually only one becomes fully developed. When the embryo-sac has reached a certain stage of growth, a development of cellular tissue takes place within it by free cell formation. This occurs in all gymnospermous plants, and constitutes what is known as the *endosperm* (fig. 280, *b*). In angiospermous plants the endosperm is not formed until after fertilization, and it is rare to find any special development of cellular tissue within the embryo-sac before fertilization. But in some cases at the base of the embryo-sac a few cells are formed, which have been termed *antipodal cells*, and are frequently afterwards absorbed, or may be incorporated in the true endosperm when it is formed. The further processes of growth in gymnospermous ovules on the one hand, and angiospermous ovules on the other, differ so much that they must be noted separately.

At the apex of the embryo-sac in gymnosperms, two or more cells of the endosperm enlarge so as to form what have been termed *corpuscles* (fig. 273). Each of these divides so as to form a large lower terminal or *central cell*, and an

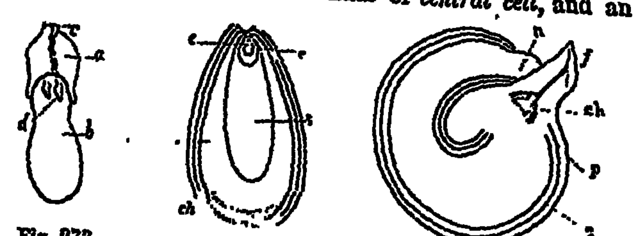

Fig. 273. Fig. 274. Fig. 275.

Fig. 273.—Vertical section of the embryo-sac *b*, and of part of the nucleus *a*, of
the ovule of the Weymouth Pine (*Pinus Strobus*). At the micropylar end of
the embryo-sac two cells, called corpuscles, *d*, have made their appearance.
Each of these is at first separated from the inner surface of the micropylar end
of the sac by a single cell, which afterwards divides into four, leaving a passage from the surface of the sac down to the corpuscle. The pollen-grain *c*,
on the summit of the nucleus, then sends down a tube which perforates the
embryo-sac, and reaches the corpuscle through the intercellular canal.
Fig. 274.—Diagram of ovule of Polygonum, showing the nucleus *n*, and the
embryo-sac *s*, containing a vesicle or germinal cell *c*, formed before impregnation. This cell, after fertilization, develops the first cell *e* of the embryo.
The dark shading at the base marks the chalaza, and the outer lines are the
integument, the micropyle being opposite the chalaza.
Fig. 275.—Campylotropous or campylotropal ovule of Wallflower (*Cheiranthus*),
showing the funiculus *f*, which attaches the ovule to the placenta; *p*, the
primine, *s*, the secundine, *n*, the nucleus, *ch*, the chalaza. The ovule is curved
upon itself, so that the foramen is near the funiculus.

upper *neck* of smaller cells (*stigmatic cells*), appearing as four when viewed from above, enclosing a *canal*. From the upper part of the central cell at the bottom of the neck, a small portion is separated—the *canal cell*. It is from a portion of the central cell that, after fertilization, the embryo is formed. Those parts all have great physiological importance in connection with fertilization. In angiosperms from the protoplasmic mass at the apex of the embryo-sac by free cell formation two (rarely one) elongated ovoid cells are produced. These are the *germinal vesicles* (fig. 274). In some angiosperms as Crocus, Maize, &c., the vesicles placed side by side are both equally elongated; to a considerable extent their lower ends are rounded, and there it is that the nucleus is found. The upper end projects into the micropyle, and is marked by distinct striæ longitudinally. This portion has been distinguished as the *filiform apparatus*. From the germinal vesicles after impregnation the embryo is formed, only one vesicle developing. This filiform apparatus is considered as corresponding to the canal cell formed from the corpuscula in gymnosperms, and it seems to serve for conducting the impregnating influence to the lower part of the central cell. In most angiosperms the germinal vesicles are placed obliquely over each other—one attached to the apex of the sac, the other lower down, and there is no filiform apparatus. Of these two vesicles the lower one alone forms an embryo, the upper one performing the same function as the filiform apparatus of other angiosperms, and the canal cell of gymnosperms. The point where the integuments are united to the base of the nucleus is called the *chalaza* (fig. 278, *ch*). This is often coloured, is of a denser texture than the surrounding tissue, and is traversed by fibro-vascular bundles, which pass from the placenta to nourish the ovule.

When the ovule is so developed that the point of union between the integuments and nucleus (the chalaza) is at the hilum (next the placenta), and the micropyle is at the opposite extremity, there being a short funiculus, the ovule is *orthotropal*, *orthotropous*, or *atropous*. This form is well seen in Polygonaceæ (fig. 271), Cistaceæ, and most gymnosperms. In such an ovule a straight line drawn from the hilum to the micropyle passes along the axis of the ovule. Where, by more rapid growth on one side than on the other, the nucleus, together with the integuments, is curved upon itself, so that the micropyle approaches the hilum, and ultimately is placed close to it, while the chalaza is at the hilum, the ovule is *campylotropal* or *campylotropous* (fig. 275) when the portions on the two sides of the line bisecting the angle of curvature are unequal, or *camptotropal* when they are equal. Curved ovules are found in Leguminosæ, Cruciferæ, and Caryophyllaceæ. Usually the opposite faces of the concavity of curvature of such ovules coalesce, and outwardly no indication of curvature is visible; but in some cases there is no coalition, and the ovule is *lecotropal*, or

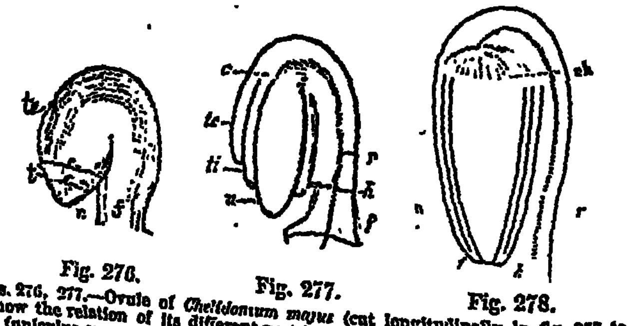

Fig. 276. Fig. 277. Fig. 278.

Fig. 278.—Anatropous or anatropal ovule of Dandelion (*Leontodon Taraxacum*),
showing the coats of the ovule surrounding the nucleus *n*, which is inverted,
so that its base *ch*, where the chalaza exists, is removed from the base or hilum
of the ovule *h*, while the foramen *f* is near the base. The connection between the
base of the ovule and the base of the nucleus at *s* is kept up by means of the raphe *r*.

horse-shoe shaped. The inverted, *anatropal*, or *anatropous* ovule (figs. 276; 277, 278) is the commonest form amongst

angiosperms. In this ovule the apex with the micropyle is turned towards the point of attachment of the funiculus to the placenta, the chalaza being situated at the opposite extremity; and the funiculus, which runs along the side usually next the placenta, coalesces with the ovule and constitutes the *raphe* (*r*), which often forms a ridge. The anatropal ovule arises from the placenta as a straight or only slightly curved cellular process, and as it grows, gradually becomes inverted, curving from the point of origin of the integuments. As the first integument (secundine) grows round it, the amount of inversion increases, and the funiculus becomes adherent to the side of the nucleus. Then if a primine be formed it covers all the free part of the ovule, but does not form on the side to which the raphe is adherent. Some anatropal ovules, however, seem to be formed in a different manner, the nucleus arising as a lateral bud from the apex of the funiculus, as in some Compositæ. These may be taken as the three types of ovule in the vegetable kingdom; but there are various intermediate forms, such as *semi-anatropal*, *amphitropal*, and *heterotropal* (transverse) ovules, where the funiculus is only, as it were, partially attached along one side, becoming free in the middle.

The position of the ovule relative to the ovary varies. When there is a single ovule, with its axis vertical, it may be attached to the placenta at the base of the ovary (*basal placenta*), and it is then *erect*, as in Polygonaceæ and Compositæ; or it may be inserted a little above the base, on a parietal placenta, with its apex upwards, and then is *ascending*, as in Parietaria. It may hang from an apicilar placenta at the summit of the ovary, its apex being directed downwards, and is *inverted* or *pendulous*, as in Hippuris vulgaris; or from a parietal placenta near the summit, and then is *suspended*, as in Daphne Mezereum,
XIII. Polygalaceæ, and Euphorbiaceæ. Sometimes a long funiculus arises from a basal placenta, reaches the summit of the ovary, and there bending over suspends the ovule, as in Armeria (Sea-pink); at other times the hilum appears to be in the middle, and the ovule becomes *horizontal*, *peltate*, or *peritropous*. When there are two ovules in the same cell, they may be either *collateral*, that is, placed side by side (fig. 257), or the one may be erect and the other inverted, as in some species of Spiræa and Æsculus; or they may be placed one above another, each directed similarly, as is the case in ovaries containing a moderate or definite number of ovules. Thus, in the ovary of Leguminous plants (fig. 256), the ovules *o*, are attached to the extended marginal placenta, one above the other, forming usually two parallel rows corresponding to each margin of the carpel. When the ovules are *definite* (*i.e.*, are uniform, and can be counted), it is usual to find their attachment so constant as to afford good characters for classification. When the ovules are very numerous (*indefinite*), while at the same time the placenta is not much developed, their position exhibits great variation, some being directed upwards, others downwards, others transversely; and their form is altered by pressure into various polyhedral shapes. In such cases it frequently happens that some of the ovules are arrested in their development and become abortive.

The homology of the ovule is by no means the same in all plants. In such cases as Polygonum and Piperaceæ, it represents the termination of the floral axis, and therefore is of the nature of a caulome. Again, in such plants as Primulaceæ and Compositæ, it is produced laterally upon the axis, and therefore represents a leaf, the integuments representing the lamina, and the funiculus the petiole,—the nucleus being an outgrowth from them. In some instances of malformation a transformation into these parts actually takes place. In cases where they are produced on the margin of the carpellary leaves (the usual mode), the ovules represent lobes of a leaf, and in some cases of monstrosity, as in Delphinium elatum, they appear as lobes of the carpellary leaf, whilst in Cupressus they are evidently outgrowths of the leaf. Further, the ovules in Orchidaceæ must be considered as mere trichomes, as they have no fibro-vascular bundles, and are developed from superficial cells of the placenta.

When the pistil has reached a certain stage in growth it becomes ready for fertilization. Pollination having been effected, and the pollen-grain having reached the stigma in angiosperms, the summit of the nucleus in gymnosperms, it is detained there, and the viscid secretion from the glands of the stigma in the former case, and the moisture from the ovule in the latter, induce the protrusion of the intine as a pollen-tube through the pores or points of perforation of the grain, many or few tubes being formed according to the number of pores. The pollen-tube or tubes pass down the canal (fig. 279), through the conducting tissue of the style when present, and reach the interior of the ovary in angiosperms, and then pass to the micropyle of the ovule, one pollen-tube going to each ovule. Sometimes the micropyle lies close to the base of the style, and then the pollen-tube enters it at once, but frequently it has to pass

Fertilization.

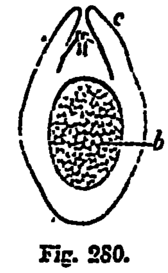

Fig. 280.

FIG. 279.—Pistil and pollen of Polygonum 1 Stigma, *stig*, with pollen-grains *p* adherent to it, sending tubes *tp* down the conducting tissue of the style *st l*; the ovary *o* containing the ovule with its covering and central cellular mass or nucleus *n*, containing a rudimentary embryo-sac *re*, in which ultimately the embryo is developed. The base of the ovule attached to the placenta is marked by the chalaza *ch*. 2. Pollen-grain *p*, separated, with pollen-tube *tp*.

FIG. 280.—Vertical section of the ovule of the Scotch Fir (*Pinus sylvestris*) in May of the second year, showing the enlarged embryo-sac *b*, full of endospermal cells, and pollen-tubes *c*, penetrating the summit of the nucleus after the pollen has entered the large micropyle of the ovule.

some distance into the ovary, being guided in its direction by various contrivances, as hairs, grooves, &c. In gymnosperms the pollen-grain resting on the apex of the nucleus sends out its pollen-tubes, which at once penetrate the nucleus of the ovule (fig. 280). In angiosperms when

the fruit, frequently incorporated with which are other parts of the flower, as receptacle, calyx, &c. In gymnosperms the pollen-tubes, having penetrated a certain distance down the tissue of the nucleus, are usually arrested in growth for a longer or shorter period, sometimes nearly a year. Subsequently growth recommences; the tube advances to the apex of the embryo-sac, which it pierces, and reaches the mouth of the canal of the corpuscle. It either descends the canal or remains attached at the mouth. The fovilla is transmitted to the central cell, and fertilization is complete, the central cell giving rise to the embryo. In angiosperms usually only one embryonal vesicle is fertilized, and one embryo is produced—*monoembryony*; but in some plants where many embryonal vesicles are formed, as in Citrus and Scabiosa, several of them may be fertilized, and thus many embryos produced—*polyembryony*. Usually, however, only one develops, so as to be capable of germination or growth. In gymnosperms it is very common to have polyembryony, although produced in a different way, for each central cell of a corpuscle may produce four embryos, and as the central cell of more than one corpuscle may be fertilized a great many embryos may be formed. They do not, however, all come to maturity.

4. *Female Organs of Phanerogams after Fertilization.*

a.—The Fruit.

Fruit After fertilization various changes take place in the parts of the flower. Those more immediately concerned in the process, the anther and stigma, rapidly wither and decay, while the filaments and style often remain for some time; the floral envelopes become dry, the petals fall, and the sepals are either deciduous, or remain persistent in an altered form; the ovary becomes enlarged, forming the *pericarp*; and the ovules are developed as the *seeds*, containing the *embryo-plant*. The term *fruit* is strictly applied to the mature pistil or ovary, with the seeds in its interior. But it often includes other parts of the flower, such as the bracts and floral envelopes. Thus the fruit of the Hazel and Oak consists of the ovary and bracts and calyx combined; that of the Apple, Pear, and Gooseberry, of the ovary and calyx; and that of the Pine-apple, of the ovaries and floral envelopes of several flowers combined. Such fruits are by some distinguished as *pseudocarps*. In popular language, the fruit includes all those parts which exhibit a striking change as the result of fertilization. In general, the fruit is not ripened unless fertilization has been effected; but cases occur in which the fruit swells, and becomes to all appearance perfect, while no seeds are produced. Thus, there are seedless Oranges, Grapes, and Pine-Apples. When the ovules are unfertilized, it is common to find that the ovary withers and does not come to maturity; but in the case of Bananas, Plantains, and Bread-fruit, the non-development of seeds seems to lead to a larger growth, and a greater succulence of fruit.

The fruit, like the ovary, may be formed of a single carpel, or of several. It may have one cell or cavity, being *unilocular*; or many, *multilocular*, &c. The number and nature of the divisions depend on the number of carpels, and the extent to which their edges are folded inwards. The appearances presented by the ovary do not always remain permanent in the fruit. Great changes are observed to take place, not merely as regards the increased size of the ovary, its softening and hardening, but also in its internal structure, owing to the suppression, additional formation, or enlargement of parts. Thus, in the Ash (fig. 281) an ovary with two cells, each containing an ovule attached to a central placenta, is changed into a unilocular fruit with one seed; one ovule, *l*, becoming abortive, while the other, *g*, gradually enlarging until the septum is pushed to one side, unites with the walls of the cell, and the placenta appears to be parietal. In the Oak and Hazel, an ovary with three cells, and two ovules in each, changes into a one-celled fruit with one seed. In the Coco-nut, a trilocular and triovular ovary is changed into a one-celled, one-seeded fruit. This abortion may depend on the pressure caused by the development of certain ovules, or it may proceed from non-fertilization of all the ovules and consequent non-enlargement of the carpels. Again, by the growth of the placenta, or the folding inwards of parts of the carpels, divisions occur in the fruit which did not exist in the ovary. In Pretrea zanzibarica, a one-celled ovary is changed into a four-celled fruit by the extension of the placenta. In Cathartocarpus Fistula a one celled ovary is changed into a fruit, having each of its seeds in a separate cell, in consequence of spurious dissepiments (*phragmata*) being produced in a horizontal manner, from the inner wall of the ovary. In Linum, by the folding inwards of the

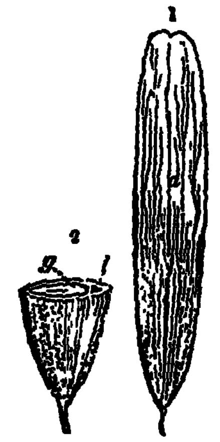

Fig. 281.

FIG. 281.—Samara or Samaroid fruit of *Fraxinus oxyphylla*. 1 Entire, with its wing *a*. 2. Lower portion cut transversely, to show that it consists of two loculaments; one of which, *l*, is abortive, and is reduced to a very small cavity, while the other is much enlarged, and filled with a seed *g*.
FIG. 282.—Drupe of the Cherry (*Cerasus*), cut vertically, showing the skin, or epicarp *ep*, the flesh or mesocarp *me*, and the stone, putamen, or endocarp *en*, enclosing the seed *g*, with the embryo.

back of the carpels a five-celled ovary becomes a ten-celled fruit. In Astragalus, the folding inwards of the dorsal suture converts a one-celled ovary into a two-celled fruit; and in Oxytropis the folding of the ventral suture gives rise to a similar change in the fruit. The development of cellular or pulpy matter, and the enlargement of parts not forming whorls of the flower, frequently alter the appearance of the fruit, and render it difficult to discover its formation. In the Gooseberry, Grape, Guava, Tomato, and Pomegranate, the seeds nestle in pulp, formed apparently by the placentas. In the Orange, the pulpy matter surrounding the seeds is formed by succulent cells, which are produced from the inner partitioned lining of the pericarp. In the Strawberry the receptacle becomes succulent, and bears the carpels on its convex surface (fig. 154); in the Rose there is a fleshy hollow torus or disk, which bears the carpels on its concave surface (fig. 155). In the Juniper the scaly bracts grow up round the seeds and become succulent, and in the Fig (fig. 150) the receptacle becomes succulent and encloses an inflorescence.

The pistil, in its simplest state, consists of a carpel or folded leaf, with ovules at its margin; and the same structure will be found in the fruit, where the pericarp represents the carpellary leaf, and the seeds correspond to the ovules. The pericarp consists usually of three layers, the external, or *epicarp* (fig. 282, *ep*), corresponding to the lower epidermis of the leaf; the middle, or *mesocarp*, *me*, representing the parenchyma of the leaf; and the internal, or *endocarp*, *en*, equivalent to the upper epidermis of the leaf, or the epithelium of the ovary. These layers are well seen in such

a fruit as the Peach or Plum, where they are separable one from the other; in them the epicarp forms what is commonly called the skin; the mesocarp, much developed, forms the flesh or pulp, and hence has sometimes been called *sarcocarp;* while the endocarp, hardened by the production of woody cells, forms the *stone* or *putamen,* immediately covering the kernel of the seed. The pulpy matter found in the interior of fruits, such as the Gooseberry, Grape, and Cathartocarpus Fistula, is formed from the placentas, and must not be confounded with the sarcocarp. In some fruits, as in the Nut, the three layers become blended together, and are indistinguishable. In Bladder Senna (Colutea arborescens) the pericarp retains its leaf-like appearance, but in most cases it becomes altered both in consistence and in colour. Thus in the Date the epicarp is the outer brownish skin, the pulpy matter is the mesocarp or sarcocarp, and the thin papery-like lining is the endocarp covering the hard seed. In the Medlar the endocarp becomes of a stony hardness. In the Melon the epicarp and endocarp are very thin, while the mesocarp forms the bulk of the fruit, differing in texture and taste in its external and internal parts. The rind of the Orange consists of epicarp and mesocarp, while the endocarp forms partitions in the interior, filled with pulpy cells. The part of the pericarp attached to the peduncle is called its *base,* and the point where the style or stigma existed is the *apex.* This latter is not always the apparent apex, as in the case of the ovary; it may be lateral or even basilar. The style sometimes remains in a hardened form, rendering the fruit *apiculate;* at other times it falls off, leaving only traces of its existence. The presence of the style or stigma serves to distinguish certain single-seeded pericarps from seeds.

hiscence ruits. When the fruit is mature and the contained seeds ripe, the carpels usually give way either at the ventral or dorsal suture or at both, and so allow the seeds to escape. The fruit in this case is *dehiscent.* But some fruits are *indehiscent,* falling to the ground entire, and the seeds eventually reaching the soil by their decay. By *dehiscence* the pericarp becomes divided into different pieces, or *valves,* the fruit being *univalvular, bivalvular,* or *multivalvular,* &c., according as there are one, two, or many valves. The splitting may extend the whole length of the fruit, or it may be only partial, the valves forming teeth at the apex of the fruit, and the dehiscence being *apicilar,* as in Caryophyllaceæ (fig. 283). Sometimes the valves are detached only at certain points, and thus dehiscence takes
te I. 2. place by pores at the apex, as in Poppy (fig. 269), or at the base, as in Campanula. Indehiscent fruits are either dry, as the Nut, or fleshy, as the Cherry and Apple. They may be formed of one or several carpels. In the former case they usually contain only a single seed, which may become so incorporated with the pericarp as to appear to be naked. Such fruits are called *pseudospermous* or false-seeded, and are exemplified in the grain of Wheat. In such cases the presence of the style or stigma determines their true nature.

Dehiscent fruits, when composed of single carpels, may open by the ventral suture only, as in the Pæony, Hellebore, Aquilegia (fig. 300), and Caltha; by the dorsal suture only, as in Magnolias and some Proteaceæ, or by both together, as in the Pea (fig. 256) and Bean; in these cases the dehiscence is called *sutural.* When composed of several united carpels, two types of dehiscence may be recognized—a longitudinal type and a transverse type. In the longitudinal type the separation may take place by the dissepiments throughout their length, so that the fruit is resolved into its original carpels, and each valve will be a carpel, as in Rhododendron, Colchicum, &c. This dehiscence, in consequence of taking place through the lamellæ of the septum, is called *septicidal* (figs. 284, 285). The valves may separate from their commissure, or central line of union, carrying the placentas with them, or they may leave the latter in the centre, so as to form with the

FIG. 283.—Seed-vessel or capsule of Campion (*Lychnis*), opening by ten teeth at the apex. The placenta is free central. The calyx is seen surrounding the seed-vessel, but not adherent.
FIG. 284.—Fruit or capsule of Meadow Saffron (*Colchicum autumnale*), dehiscing by three valves in a septicidal manner. The fruit is thus resolved into its three component carpels, with their styles and stigmas.
FIG. 285.—Diagram to illustrate the septicidal dehiscence in a pentalocular capsule. The loculaments *l* correspond to the number of the carpels, which separate by splitting through the septa *s*.
FIG. 286.—The seed vessel (capsule) of the Flower-de-Luce (*Iris*), opening in a loculicidal manner. The three valves bear the septa in the centre, and the opening takes place through the back of the loculaments. Each valve is formed by the halves of contiguous carpels.
FIG. 287.—Diagram to illustrate loculicidal dehiscence. The loculaments *l*, split at the back, and the valves separate, bearing the septa *s* on their centres.
FIG. 288.—Diagram to illustrate septifragal dehiscence, in which the dehiscence takes place through the back of the loculaments *l*, and the valves separate from the septa *s*, which are left attached to the placentas in the centre.

axis a column of a cylindrical, conical, or prismatic shape, which is termed the *columella.* The union between the edges of the carpels may be persistent, and they may dehisce by the dorsal suture, or through the back of the loculaments, as in the Lily and Iris (figs. 286, 287). In these cases each valve consists of a half of each of two contiguous carpels. The placentas either remain united to the axis, or they separate from it, being attached to the septa on the valves. This dehiscence is *loculicidal.* When the outer walls of the carpels break off from the septa, leaving them attached to the columella, the dehiscence is said to be *septifragal* (fig. 288), and where, as in Linum catharticum and Calluna, the splitting takes place first of all in a septicidal manner, the fruit is described as *septicidally septifragal;* while in other cases, as in Thorn Apple (Datura Stramonium), where the splitting is at first loculicidal, the dehiscence is *loculicidally septifragal.* In all those forms the separation of the valves takes place either from above downwards or from below upwards. But when the splitting only extends for a short distance, then dehiscence takes

dehiscence. In Saxifraga a splitting for a short distance of the ventral sutures of the carpels takes place, so that a single large apical pore is formed. In Caryophyllaceæ (fig. 283) numerous small valvular splittings occur, forming teeth at the apex, and a single apical orifice is formed. In the fruit of Cruciferæ, as Wallflower, there is a form of longitudinal dehiscence (fig. 289) in which the valves separate from the base of the fruit, leaving a central *replum*, or frame, which is a phragma formed by a prolongation from the parietal placentas on opposite sides of the fruit, extending between the ventral sutures of the carpels. In Orchidaceæ (fig. 290) the pericarp, when ripe, separates into three valves, in a loculicidal manner, but the midribs of the carpels, to which the placentas are attached, remain adherent to the axis both at the apex and base, and form three arches, bearing the seeds, after the valves have fallen. In fruits with a free central placenta it is sometimes difficult to tell whether the dehiscence is septicidal or loculicidal, inasmuch as there are no dissepiments, and the placentas and seeds form a column in the axis. Their number, as well as alternation or opposition, as compared with the sepals, will aid in determining whether the valves are the entire carpellary leaves, as in septicidal dehiscence, or only half carpels united, as in loculicidal dehiscence. The other type of dehiscence is transverse, the dehiscence in this case being called *circumscissile*. In this dehiscence the upper part of the united carpels falls off in the form of a lid or operculum, as in Anagallis and in Henbane (Hyoscyamus) (fig. 291), and hence the fruit is often denominated *operculate*. In such instances we may either suppose that the fruit or seed-vessel is formed by a number of articulated leaves like those of the Orange, the division taking place where the laminæ join the petioles, or that the receptacle is prolonged in the form of a hollow cup, and the lid represents leaves united to it by articulation.

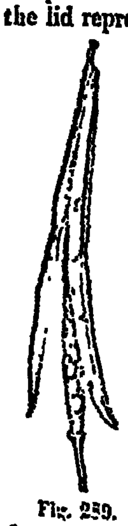

Fig. 291.

Fig. 289. Fig. 292.

FIG. 289.—Siliqua or seed-vessel of Wallflower (*Cheiranthus Cheiri*), opening by two valves, which separate from the base upwards, leaving the seeds attached to the placentas in the middle, with a replum between.

FIG. 290.—Seed-vessel of an Orchid (*Orchis*), opening by three valves v v v, which bear the placentas and seeds in their middle. The midribs of the carpels remain united at the base and apex, and the withered floral envelopes e are seen attached at the apex.

FIG. 291.—Seed-vessel of Henbane (*Hyoscyamus niger*), opening by circumscissile dehiscence. The upper part of the seed-vessel comes off in the form of a lid, and the capsule has been on this account called pyxis or pyxidium.

FIG. 292.—The fruit of the Fennel (*Fœniculum vulgare*), arrived at maturity. It separates into two cocci or achænia, each of which is marked with obtuse prominent ridges on the surface, and is suspended from the summit of a process of the axis (columella), called a carpophore.

FIG. 293.—Lomentum or lomentaceous legume of a species of Sainfoin (*Hedysarum*). Each seed is contained in a separate cavity by the folding inwards of the walls of the legume at equal intervals; and the legume, when ripe, separates transversely into single-seeded portions or mericarps.

Sometimes the axis is prolonged beyond the base of the
III carpels, as in the Mallow and Castor-oil plant, the carpels being united to it throughout their length by their faces, and separating from it without opening. In the Umbelliferæ the two carpels separate from the lower part of the axis, and remain attached by their apices to a prolongation of it, called a *carpophore* or *podocarp*, which splits into two (fig. 292) and suspends them; hence the name *cremocarp* is applied to this fruit, which divides into two suspended mericarps. The general term *schizocarp* is applied to all dry fruits, which break up into two or more one-seeded indehiscent mericarps, as in Hedysarum (fig. 293). In Geraniaceæ the axis is prolonged beyond the carpels, forming a carpophore, to which the styles are attached, and the pericarps separate from below upwards, before dehiscing by their ventral suture (fig. 152). Carpels which separate one from another in this manner are called *cocci*. They are well seen in Euphorbiaceæ, where there are Plate XIII.
usually three such carpels, and the fruit is designated fig. 7.
tricoccous. In many of them, as Hura crepitans, the cocci separate with great force and elasticity, the cells being called *dissilient*. In many Leguminous plants, such as Ornithopus, Hedysarum (fig. 293), Entada, Coronilla, and the Gum-arabic plant (Acacia arabica), the fruit becomes a schizocarp by the formation of transverse partitions from the folding in of the sides of the pericarp, and distinct separations taking place at these partitions by what has been termed *solubility*. In Cathartocarpus Fistula the schizocarp exhibits no evident depressions externally. Some look upon these pods as formed by pinnate leaves folded, and the divisions as indicating the points where the different pairs of pinnæ are united.

Fruits may be formed by one flower, or they may be the product of several flowers combined. In the former case they are either *apocarpous*, of one mature carpel or of several separate free carpels; or *syncarpous*, of several carpels, more or less completely united. These different kinds of fruits may be *indehiscent* or *dehiscent*. When the fruit is composed of the ovaries of several flowers united, it is usual to find the bracts and floral envelopes also joined with them, so as to form one mass; hence such fruits are called *multiple*, *confluent*, or *anthocarpous*. The term *simple* is perhaps properly applied to fruits which are formed by the ovary of a single flower, whether they are composed of one or several carpels, and whether these carpels are separate or

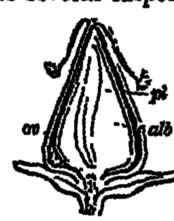

Fig. 294.

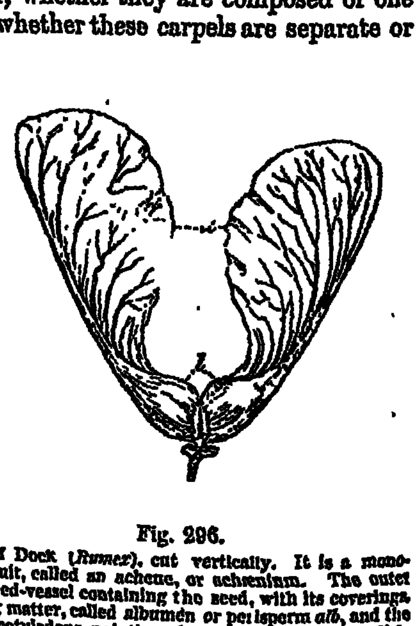

Fig. 295. Fig. 296.

FIG. 294.—Fruit of a species of Dock (*Rumex*), cut vertically. It is a monospermous indehiscent dry fruit, called an achene, or achænium. The outer part, ov, is the pericarp or seed-vessel containing the seed, with its coverings. The seed contains nourishing matter, called albumen or perisperm *alb*, and the embryo plant *pl*, with its cotyledons pointing downwards, and its radicle upwards. The seed is orthotropal, and the embryo is inverted. At the upper part of the pericarp two of the styles and stigmas are seen curving downwards. At the base part of the perianth is represented.

FIG. 295.—Achænium of Crowfoot (*Ranunculus*). A single-seeded seed-vessel, with the pericarp applied closely to the seed. Such fruits resemble seed in appearance; the style and stigma *s* aid in distinguishing them.

FIG. 296.—Seed-vessel of *Acer Pseudo-platanus* (Sycamore, called Plane in Scotland), composed of two samaras or winged monospermous carpels united; *a*, upper part forming a dorsal wing; *l*, lower portion corresponding to the loculaments.

combined. Simple fruits are hence sometimes denominated *monogynœcial*, as being formed by one gynœcium; while multiple fruits are called *polygynœcial*, as being formed by many gynœcia.

Simple fruits are either *dry* or *succulent*,—the pericarp, in the former instance, remaining more or less foliaceous in its structure, and sometimes being incorporated with the seed, while it is in the latter thick and fleshy or pulpy.

s of The *achænium* is a dry unilocular monospermous indehiscent fruit, the pericarp of which is closely applied to the seed, but separable from it. It may be *solitary*, forming a single fruit, as in the Dock (fig. 294), and in the
IV. Cashew, where it is supported on a fleshy peduncle; or *aggregate*, as in Ranunculus (figs. 254, 295), where several achænia are placed on a common elevated receptacle. In the Strawberry the achænia (fig. 154) are aggregated on a convex succulent receptacle. In the Rose they are supported on a concave receptacle (fig. 155), and in the Fig the succulent receptacle completely encloses the achenes (fig. 150). In Dorstenia (fig. 163) the achenes are situated on a flat or slightly concave receptacle. In the Rose the aggregate achænia with their covering are sometimes collectively called *cynarrhodum*. It will thus be remarked that what in common language are called the seeds of the Strawberry, Rose, and Fig, are in reality carpels, which are distinguished from seeds by the presence of styles and stigmas. The styles occasionally remain attached to the achænia, in the form of feathery appendages, as in Clematis, and they are called *caudate*. In Compositæ, the fruit,
e IX. which is sometimes called *cypsela*, is an achænium (fig. 197), to which the pappose or obsolete calyx remains adherent. Such is also the nature of the fruit in Dipsacaceæ. When the pericarp is thin, and appears like a bladder surrounding the seed, the achænium is termed a *utricle*, as in Amarantaceæ. When the pericarp is extended in the form of a winged appendage, a *samara* or *samaroid achænium* is produced, as in the Ash (fig. 281), Common Sycamore (fig. 296), and Hiræa. In these cases there are usually two achænia united, one of which, however, as in Fraxinus oxyphylla (fig. 281), may be abortive. The wing is either *dorsal*, that is, it is a prolongation from the median vein (fig. 296, *a*) or it is *marginal*, that is, formed by the lateral veins. It surrounds the fruit longitudinally in the Elm. When the pericarp becomes so incorporated with the seed as to be inseparable from it, as in grains of Wheat, Maize, Oats (fig. 297), and other Grasses, then the name

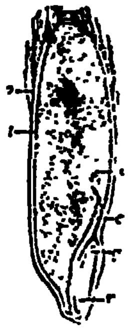

Fig. 297.

Fig. 298.

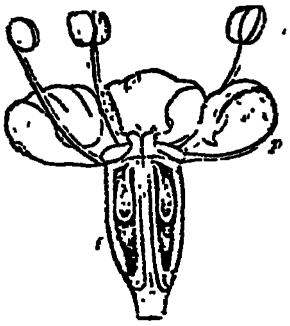

Fig. 299.

Fig. 297.—Caryopsis or single-seeded grain of Oats (*Avena*). The fruit and seed are incorporated. The pericarp *o* bears the styles and stigmas, and encloses the seed *t*, with its albumen, or perisperm, *a*, and its embryo, consisting of the cotyledon *c*, the gemmule *g*, and the root *r*.

Fig. 298.—Calyx and fruit of Comfrey (*Symphytum*), cut vertically. The fruit is divided by the folding of the ovary into four single-seeded portions or achænia, two of which are seen in the figure, and the style appears to arise from the base of the carpels.

Fig. 299.—Flower of Fennel (*Fœniculum vulgare*), one of the Umbelliferæ, cut vertically, showing the fruit *f*, composed of two single-seeded carpels, or achenes, united, so as to form a cremocarp. The pendulous seeds are seen in the carpels or mericarps. The two styles are seen at the apex of the fruit, with their dilated bases formed by an epigynous disk. The points (apicula) of the petals *p* are turned inwards. The calyx tube is adherent to the fruit, and the limb of the calyx is often obsolete.

caryopsis is given. There are some fruits which consist of two or more achænia, although originally the carpels were united into a syncarpous pistil, as in Labiatæ and Boraginaceæ (fig. 298). To this form of schizocarpic fruit,
ate III. as well as to that of Tropæolum and Mallow, the name *carcerulus* is given. The *cremocarp*, or the fruit of Umbelliferæ (figs. 292 and 299), is composed of two achænia Plate VI.
united by a commissure to a *carpophore*, from which they are suspended at maturity. It is sometimes denominated *diachænium*, from the union of two achænia, which in this instance receive the name of *mericarps* or *hemicarps*.

The *nut* or *glans* is a dry one-celled indehiscent fruit with a hardened pericarp, surrounded by bracts at the base, and, when mature, containing only one seed. In the young state the ovary contains two or more ovules, but only one comes to maturity. It is illustrated by the fruits of the Hazel and Chestnut, which are covered by leafy bracts, in the form of a *husk*, and by the Acorn, in which the bracts and receptacle form a *cupula* or *cup* (fig. 147). The parts of the pericarp of the nut are united so as to appear one. In common language the term nut is very vaguely applied both to fruit and seeds.

The *drupe* is a succulent usually monospermal and unilocular indehiscent fruit, with a pericarp easily distinguishable into epicarp, mesocarp, and endocarp. This term is applied to such fruits as the Cherry (fig. 282), Peach, Plate XII.
Plum, Apricot, Mango, Walnut, Nutmeg, and Date. The endocarp is usually hard, forming the stone (*putamen*) of the fruit, which encloses the kernel or seed. The mesocarp is generally pulpy and succulent, so as to be truly a *sarcocarp*, as in the Peach, but it is sometimes of a tough texture, as in the Almond, and at other times is more or less fibrous, as in the Coco-nut. In the Almond there are often two ovules formed, only one of which comes to perfection. In the Walnut, prolongations from the endocarp, which is of two layers, extend into the substance of the seed, and give rise to its characteristic convoluted lobate appearance. This fruit has been sometimes called *tryma*. In the Raspberry and Bramble several drupes or *drupels* are aggregated so as to constitute an *etærio*.

The *follicle* is a dry monocarpellary unilocular polyspermal (many-seeded) fruit, dehiscing by the ventral suture. It is rare to meet with a solitary follicle forming the fruit. There are usually several aggregated together, either in a circular manner on a shortened receptacle, as in Hellebore, Aconite, Delphinium, Aquilegia (figs. 300, 301) Crassulaceæ (fig. 172), Butomus, and Asclepiadaceæ; or in a spiral manner on an elongated receptacle, as in Magnolia, Banksia, and Liriodendron. Occasionally, follicles dehisce by the dorsal suture, as in Magnolia grandiflora and Banksia.

The *legume* or *pod* is a dry monocarpellary unilocular polyspermal fruit, dehiscing both by the ventral and the dorsal Plate V
suture. It characterises Leguminous plants, as the Bean fig. 7.
and Pea (fig. 256). In the Bladder-senna it retains its leaf-like appearance, and forms an inflated legume. In some Leguminosæ, as Arachis, Cathartocarpus Fistula, and the Tamarind, the fruit must be considered a legume, although it does not dehisce. The first of these plants produces its fruit underground, and is called earth-nut; the second has a partitioned legume and is schizocarpic; and both the second and third have pulpy matter surrounding the seeds. Some legumes are schizocarpic by the formation of constrictions externally. Such a form is the [illegible]

mass, formed by the placentas. The name is usually given to such fruits as the Gooseberry (fig. 302) and Currant, in which the ovary is inferior, and the placentas are parietal, the seeds being ultimately detached from the placenta, and

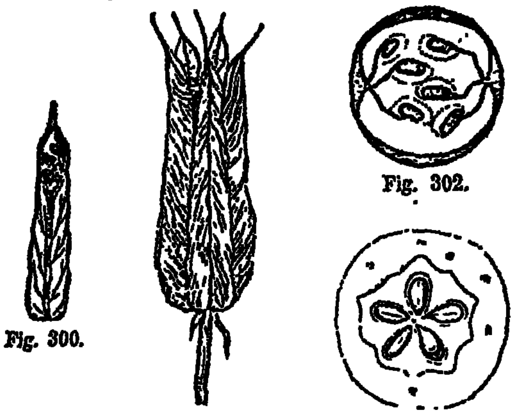

Fig. 300. Fig. 301. Fig. 302. Fig. 303.

FIG. 300.—Follicle of Columbine (*Aquilegia vulgaris*), consisting of a polyspermal carpel, opening by the ventral suture.
FIG. 301.—Apocarpous fruit of Columbine (*Aquilegia vulgaris*), consisting of five separate mature carpels, with styles and stigmas.
FIG. 302.—Fruit of the Gooseberry (*Ribes Grossularia*), cut vertically, showing the seeds attached to parietal placentas, and immersed in pulpy matter, which is formed partly from the endocarp and partly from the testa of the seed. The fruit is called a bacca.
FIG. 303.—Section of the fruit of the Apple (*Pyrus Malus*), consisting of a fleshy covering partly formed by the calyx and disk, and five cavities in the centre with seeds. The fruit is called a pome.

lying loose in the pulp. Others have applied it also to those in which the ovary is superior, as in the Grape, Potato, and Ardisia, and the placentas are central or free central. The latter are frequently separated under the name *uva* (grape). In general, the name of *baccate* or *berried* is applied to all pulpy fruits. In the Pomegranate there is a peculiar baccate many-called inferior fruit, having a tough rind, enclosing two rows of carpels placed one above the other. The seeds are immersed in pulp, and are attached irregularly to the parietes, base, and centre of the loculi. The fruit has been called *balausta*, and the tough rind is called *malicorium*. In the Baobab there is a multilocular syncarpous fruit, in which the seeds are immersed in pulp, to which the name *amphisarca* is given.

The *pepo* or *peponida*, another indehiscent syncarpous fruit, is illustrated by the fruit of the Gourd, Melon (fig. 262), and other Cucurbitaceæ. It is formed of three carpels, to which the calyx is superior; the rind is thick and fleshy, partly formed by the calyx; and there are three or more seed-bearing parietal placentas, either surrounding
Plate VI. a central cavity, or prolonged inwards into it. The fruit of the Papaw resembles the pepo, but the calyx is not superior.

The *hesperidium* is the name given to such indehiscent syncarpous fruits as the Orange, Lemon, and Shaddock, in which the epicarp and mesocarp form a separable rind, and the endocarp sends prolongations inwards, forming triangular divisions, to the inner angle of which the seeds are attached, pulpy cells being developed around them. Both pepo and hesperidium may be considered as modifications of the berry.

The *pome*, seen in the Apple, Pear, Quince, Medlar, and Hawthorn, is a fleshy indehiscent syncarpous fruit with the calyx attached, and has an outer skin or epicarp, a fleshy mesocarp, and a scaly or horny endocarp (the *core*) enclosing the seeds (fig. 303). Some look upon the so-called epicarp and mesocarp as formed by the prolonged receptacle on the inner surface of which a fleshy lining is developed, while the endocarp represents the true carpels. In this view the docarp might be regarded as consisting of a number of lehiscent follicles (usually five) surrounded by a succulent ceptacle. In the Medlar the endocarp (or what may be called the true pericarp) is of a stony hardness, while the outer succulent covering is open at the summit. The stones of the Medlar are called *pyrenæ*; some apply the term *nuculanium* to the Medlar. Taking this view of the pome it may be said to resemble in a manner the fruit of the Rose, the cynarrhodum producing achenes, and the pome closed follicles.

The name *capsule* is applied generally to all dry syncarpous fruits, which dehisce by valves of whatever kind. Plate X. fig. 6. Plate XI fig. 5.
It may thus be unilocular or multilocular, monospermous or polyspermous. The true valvular capsule is observed in Colchicum (fig. 284), Lily, and Iris (fig. 286). The *porose capsule* is seen in the Poppy (fig. 269), Antirrhinum majus, Plate I.
and Campanula persicifolia. In Campanula the pores occur at the base of the capsule, and it has been designated a *diplotegia*. When the capsule opens by a lid, or by circumscissile dehiscence, it is called a *pyxidium*, as in Anagallis arvensis, Henbane (fig. 291), and Monkey pot (Lecythis). The capsule assumes a screw-like form in Helicteres, and a star-like or stellate form in Illicium anisatum. In certain instances the cells of the capsule separate from each other, and open with elasticity to scatter the seeds. This kind of capsule is met with in the Sandbox tree (Hura crepitans), and other Euphorbiaceæ, Plate XIII.
where the cocci, containing each a single seed, burst asunder fig. 7.
with force; and in Geraniaceæ, where the cocci, each con- Plate II.
taining, when mature, usually one seed, separate from the carpophore, become curved upwards by their adherent styles, and open by the ventral suture (fig. 152). In the former case the fruit collectively has been called *regma*.

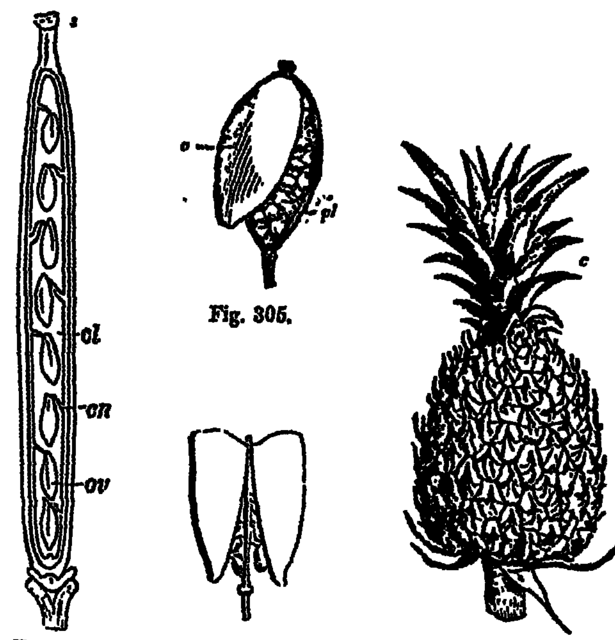

Fig. 304. Fig. 305. Fig. 306. Fig. 307.

FIG. 304.—Compound ovary (siliqua) of Wallflower (*Cheiranthus*), consisting of at least two carpels united. One valve has been removed to show the partition or replum *cl*, formed of a double layer from the placentæ *cn* on either side, to which the ovules *ov* are attached by means of funiculi. The style and stigma *s* are at the upper part of the ovary.
FIG. 305.—Silicula of Whitlow-grass (*Draba*), opening by two flat valves *o* from below upwards, leaving the parietal placentas *pl* in the centre, united by a membrane or replum. The partition of the seed-vessel is broad, and hence the name latiseptæ.
FIG. 306.—Silicula or pouch of Shepherd's purse (*Capsella*), opening by two folded valves, which separate from below upwards. The phragma is narrow, and hence the name angustiseptæ.
FIG. 307.—Fruit of the Pine-apple (*Ananassa sativa*), consisting of numerous flowers and bracts united together so as to form a collective or anthocarpous fruit. The crown of the Pine-apple, *c*, consists of a series of empty bracts prolonged beyond the fruit.

The *siliqua* is a dry syncarpous bicarpellary bilocular polyspermal fruit with a replum, dehiscing by two valves from below upwards, the valves separating from the placentas and leaving them united by the replum. The seeds are attached on both sides of the replum, either in one row or in two. When the fruit is long and narrow it

is called *siliqua* (fig. 304); when broad and short, it is called *silicula* (figs. 305, 306). It occurs in Cruciferous plants, as Wallflower, Cabbage, and Cress. In Glaucium and Eschscholtzia (Papaveraceous plants) the fruit is siliquæform, the dissepiment or replum being of a spongy nature, and it has been termed a *ceratium*. In its normal state a siliqua is supposed to consist of four carpels, but two of these are abortive. There are four bundles of vessels in it, one corresponding to each valve which may be called *valvular* or *pericarpial*, and others running along the edge called *placental*. The replum consists of two lamellæ. It sometimes exhibits perforations, becoming *fenestrate*. Rarely its central portion is absorbed, so that the fruit becomes one-celled. It may become *lomentaceous*, as in Raphanus and Sea-kale, and it may be reduced, as in Woad (Isatis), to a monospermal condition.

It sometimes happens that the ovaries of two flowers unite so as to form a double fruit. This may be seen in many species of Honeysuckle. But the fruits which are now to be considered consist usually of the floral envelopes, as well as the ovaries of several flowers united into one, and are called *multiple*, *confluent*, or *polygynœcial*. The term *anthocarpous* has also been applied as indicating that the floral envelopes as well as the carpels are concerned in the formation of the fruit.

The *sorosis* is a succulent multiple fruit formed by the confluence of a spike of flowers, as in the fruit of the
to XIV. Pine-apple (fig. 307), the Bread-fruit, and Jack-fruit. Sometimes a fruit of this kind resembles that formed by a single flower, and a superficial observer might have some difficulty in marking the difference.

The *syconus* is an anthocarpous fruit, in which the receptacle completely encloses numerous flowers and becomes succulent. The Fig (fig. 150) is of this nature, and what are called its seeds are the achænia of the numerous flowers scattered over the succulent hollowed receptacle. In Dorstenia (fig. 163) the axis is less deeply hollowed, and of a harder texture, the fruit exhibiting often very anomalous forms.

The *strobilus*, or *cone*, is a fruit-bearing spike, more or less elongated, covered with scales (fig. 134), each of which represents a separate flower, and has often two seeds at its base, the scales being considered as bracts and the seeds naked, and no true ovary present with its style or stigma. This fruit is seen in the cones of Firs, Spruces, Larches, and Cedars, which have received the name of Coniferæ, or cone-bearers, on this account. Cone-like fruit is also seen in some Cycadaceæ. The scales of the strobilus are sometimes thick and closely united, so as to form a more or less angular and rounded mass, as in the Cypress; while in the Juniper they become fleshy, and are so incorporated as to form a globular fruit like a berry. The dry fruit of the Cypress, and the succulent fruit of the Juniper, have received the name of *galbulus*. The fruit of the Yew (Taxus baccata) is regarded as a cone reduced to a single naked seed, covered by succulent scales, which unite to form a scarlet fleshy envelope. In the Hop the fruit is called also a strobilus, but in it the scales are thin and membranous, and the seeds are not naked but are contained in pericarps.

The same causes which produce alterations in the other parts of the flower give rise to anomalous appearances in the fruit. The carpels, in place of bearing seeds, are sometimes changed into leaves, with lobes at their margins. Leaves are sometimes produced from the upper part of the fruit, which is then called *frondiparous*. In the genus Citrus, to which the Orange and Lemon belong, it is very common to meet with a separation of the carpels, so as to produce what are called horned oranges and fingered citrons. In this case a syncarpous fruit has a tendency to become apocarpous. In the Orange we occasionally find a supernumerary row of carpels produced, giving rise to the appearance of small and imperfect oranges enclosed within the original one. The Navel Orange of Pernambuco is of this nature. It sometimes happens that, by the union of flowers, double fruits are produced. Occasionally a double fruit is produced, not by the incorporation of two flowers, but by the abnormal development of a second carpel in the flower.

ARRANGEMENT OF FRUITS.

I. Monogynœcial fruits, formed by the gynœcium of one flower.
  1. Capsulary fruits.—Dry, dehiscent, formed by one or more carpels; when by more than one, coherent.
     a. Monocarpellary.—Legume; Follicle.
     b. Polycarpellary.—Capsule; Pyxidium; Siliqua; Silicula; Ceratium; Diplotegia; Regma.
  2. Aggregate fruits.—Polycarpellary; carpels always distinct.
     a. Indehiscent.—Etærio; Strawberry; Cynarrhodum.
     b. Dehiscent.—Follicles (Columbine).
  3. Schizocarpic fruits.—Dry, breaking up into one-celled indehiscent portions.
     a. Monocarpellary.—Lomentum.
     b. Polycarpellary.—Cremocarp; Carcerulus; Samara (Acer).
  4. Achænial fruits.—Dry, indehiscent, one or few-seeded, not breaking up. Achænium; Caryopsis; Utricle; Samara (Elm); Cypsela; Glans.
  5. Baccate fruits.—Indehiscent; seeds in pulp. Bacca; Uva; Hesperidium; Pepo; Amphisarca; Balausta.
  6. Drupaceous fruits.—Indehiscent, succulent, endocarp indurated, usually stony. Drupe; Tryma; Pome; Nuculanium.

II. Polygynœcial fruits, formed by the gynœcia of several flowers.
  1. Succulent.—Sorosis; Syconus; Galbulus.
  2. Dry.—Strobilus; Cone.

b.—The Seed.

When the ovule arrives at maturity it constitutes the seed, which is contained in a seed-vessel in the plants called *angiospermous*; while in *gymnospermous plants*, such as Coniferæ and Cycadaceæ, it is naked, or, in other words, has no true pericarp. It sometimes happens in angiosperms, that the seed-vessel is ruptured at an early period of growth, so that the seeds become more or less exposed during their development; this occurs in Mignonette, where the capsule opens at the apex, and in Cuphea platycentra, where the placenta bursts through the ovary and floral envelopes, and appears as an erect process bearing the young seeds. After impregnation the ovule is greatly changed, in connection with the formation of the embryo. In the embryo-sac of most angiosperms there is a development of cellular tissue, enveloping, when not previously absorbed, the *antipodal cells*, and more or less filling the embryo sac. In gymnosperms, as already mentioned, the endosperm is formed preparatory to fertilization. The germinal vesicle in angiosperms, the central cell of the corpuscle in cryptogams, enlarges and divides, forming the embryo. The embryo-sac enlarges greatly, displacing gradually the nucleus, which may eventually form merely a thin layer around the sac, or it may completely disappear. The integuments also become much altered, and frequently appendages are developed from them. The seed

character, it has received the name of *sarcosperm* or *sarcoderm*. The nature of the testa depends upon that of the pericarp. When the pericarp is dehiscent then the seed-covering is of a strong and tough character; but when

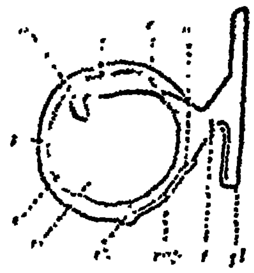

Fig. 308.

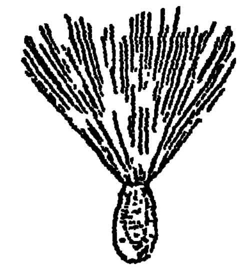

Fig. 309.

FIG. 308.—Seed (ovule) of the Pea (*Pisum*), deprived of one-half of its integument or spermoderm. The outer covering, called either episperm, exosperm, or testa, is marked t, the inner, called endopleura, e. Within these integuments is the embryo, consisting of cotyledons or seed-lobes c containing nourishing matter, the gemmule or young leaf-bud g, the radicle or young root r, the tigelle or stalk between root and bud t. The seed is attached to the placenta *pl* by a cord or funiculus *f*. The nourishing vessels *vsp* enter the nucleus at the chalaza ch, and the root of the embryo points to the micropyle or foramen *m*.
FIG. 309.—Seed of Asclepias, with a cluster of hairs arising from the edges of the micropyle, and by some considered as a hairy aril. These hairs are for the purpose of scattering the seed.

the pericarp is indehiscent and encloses the seed for a long period, its outer covering has a proportional softness. The cells of the testa are often coloured, and have projections and appendages of various kinds. Thus in Abrus precatorius and Adenanthera pavonina it is of a bright red colour; in French beans it is beautifully mottled; in the Almond it is veined; in the Tulip and Primrose it is rough; in the Snapdragon it is marked with depressions; in Cotton and Asclepias (fig. 309) it has hairs attached to it; and in *Mahogany*, *Bignonia*, and Firs it is expanded in the form of wing-like appendages (fig. 310). In Collomia, Acanthodium, and other seeds, it contains spiral cells, from which, when moistened with water, the fibres uncoil in a beautiful manner; so also in Cobæa scandens and Calempelis scaber. In the testa of the seed of *Ulmus campestris* the cells are compressed, and their sinuous boundaries are traced out by minute rectangular crystals adhering to their walls; and in such plants as the Flax (Linum) the cells are converted into mucilage. These structural peculiarities of the testa in different plants have relation to the scattering of the seed and its germination upon a suitable nidus. But in some plants the pericarps assume structures which subserve the same purpose; this especially occurs in small pericarps enclosing single seeds, as achenes, caryopsides, &c. Thus
Plate VIII fig. 3 in Compositæ (fig. 197) and Valerian, the pappose limb of the calyx forms a parachute to the pericarp; in Labiatæ and some Compositæ spiral cells are formed in the epicarp; and the epicarp is prolonged as a wing in Fraxinus (fig. 281) and Acer (fig. 296)

covering formed around the naked seed in the Yew is by some considered of the nature of an aril. On the testa, at various points, there are produced at times cellular bodies, which are not dependent on fertilization, to which the name of *strophioles*, or *caruncules*, has been given, the Plate II.
seeds being strophiolate or carunculate. These tumours fig. 5.
may occur near the base of the seed, as in Polygala, or at the apex, as in Ricinus, where they are swellings of the exostome; or they may occur in the course of the raphe, as in Blood-root and Asarabacca. The funiculi of the ovules frequently attain a great length in the seed, and in some Magnolias, when the fruit dehisces, they appear as long scarlet cords suspending the seeds outside. The hilum or umbilicus of the seed is usually well marked, as a scar of varying size, in the Calabar bean and in some species of Mucuna and Dolichos, extending along a large portion of the edge of the seed; and it frequently exhibits marked colours, being black in the Bean, white in many species of Phaseolus, &c. The *micropyle* (fig. 308, *m*) of the seed, with its exostome and endostome, may be recognizable by the naked eye, as in the Pea and Bean tribe, Iris, &c., or it may be very minute or microscopic. It indicates the true apex of the seed, and is important as marking the point to which the root of the embryo is directed. At the micropyle in the Bean is observed a small process of integument, which, when the young plant sprouts, is pushed up like a lid, and is called *embryotega*. The *chalaza* (fig. 311, *ch*) is often of a different colour from the rest of the seed. In the Orange (fig. 313) it is of a reddish-brown colour, and is easily recognized at one end of the seed when the integuments are carefully removed. In anatropal seeds the raphe forms a distinct ridge along one side of the seed (fig. 314).

Fig. 310.

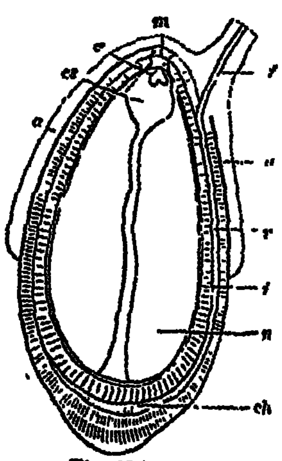

Fig. 311.

Fig. 312.

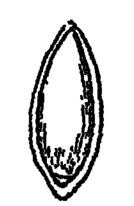

Fig. 313.

FIG. 310.—Seed of Fir (*Pinus*), with a membranous appendage *w* to the testa, called a wing. The seed is said to be *winged*.
FIG. 311.—Young anatropal seed of the White Water-lily (*Nymphæa alba*), cut vertically. It is attached to the placenta by the funiculus or umbilical cord *f*, cellular prolongations from which *form an aril a a*. The vessels of the cord are prolonged to the base of the nucleus *n* by means of the raphe *r*, composed of cells and spiral vessels. The base of the nucleus is indicated by the chalaza *ch*, while the apex is at the micropyle *m*. The covering of the seed is marked *t*. *n* is the nucleus or perisperm, surrounded by its covering, and enclosing the embryo-sac *cs*, in which the endosperm is formed. The embryo *e*, with its suspensor, is contained in the sac, the radicle pointing to the micropyle *m*.
FIG. 312.—Arillode *a*, or false aril, of the Spindle-tree (*Euonymus*), arising from the micropyle *f*.
FIG. 313.—Anatropal seed of the Orange (*Citrus Aurantium*) opened to show the chalaza *c*, which forms a brown spot at one end.

The position of the seed as regards the pericarp resembles that of the *ovule* in the ovary, and the same terms are applied—erect, ascending, pendulous, suspended, curved, &c. These terms have no reference to the mode in which the fruit is attached to the axis. Thus the seed may be erect while the fruit itself is pendent, in the ordinary meaning of that term. The part of the seed next the axis or the ventral suture is its *face*, the opposite side being the *back*. Seeds exhibit great varieties of form. They may be flattened laterally (*compressed*), or from above

downwards (*depressed*). They may be round, oval, triangular, polygonal, rolled up like a snail, as in Physostemon, or coiled up like a snake, as in Ophiocaryon paradoxum.

The endosperm formed in the embryo-sac of angiosperms after fertilization, and found previous to it in gymnosperms, consists of cells containing protoplasmic substance and starchy or fatty matter, or both, destined for the nutriment of the embryo. It arises by free-cell division from the protoplasm of the embryo-sac,—and may occupy the whole cavity of the embryo-sac, or may be formed only at certain portions of it, at the apex, as in Rhinanthus, at the base, as in Vaccinium, or in the middle, as in Veronica. As the endosperm increases in size along with the embryo-sac and the embryo, the substance of the original nucleus of the ovule is gradually absorbed, and usually at last disappears except the layer constituting the endopleura, and in some cases this goes also. Sometimes, however, as in Musaceæ, Cannaceæ, Zingiberaceæ, no endosperm is formed; the cells of the original nucleus, becoming filled with food-materials for the embryo, are not absorbed, but remain surrounding the embryo-sac with the embryo, and constitute the *perisperm*. Again, in other plants, as Nymphæaceæ (fig. 311) and Piperaceæ, both endosperm and perisperm are present. It was from observations on cases such as these that old authors, imagining a resemblance betwixt the plant-ovule and the animal ovum, applied the name *albumen* to the outer nutrient mass or perisperm, and designated the endosperm as *vitellus*. The term albumen is very generally used as including all the nutrient matter stored up as a separate mass in the ovule, but it would be advisable to discard the name as implying a definite chemical substance. There is a large class of plants in which although at first after fertilization a mass of endosperm is formed, yet, as the embryo increases in size, the nutrient matter from the endospermic cells passes out from them, and is absorbed by the cells of the embryo plant. In the mature seed, in such cases, there is no separate mass of tissue containing nutrient food-material apart from the embryo itself. Such a seed is said to be *exalbuminous*, as in Compositæ, Cruciferæ, and most Leguminosæ. When either endosperm or perisperm or both are present the seed is said to be *albuminous*.

The albumen varies much in its nature and consistence, and furnishes important characters. It may be *farinaceous* or *mealy*, consisting chiefly of cells filled with starch, as in cereal grains, where it is abundant; *fleshy* or *cartilaginous*, consisting of thicker cells which are still soft, as in the Coco-nut, and which sometimes contain oil, as in the oily albumen of Croton, Ricinus, and Poppy; *horny*, when the cell-walls are slightly thickened and capable of distension, as in Date and Coffee; and they sometimes become greatly thickened, filling up the testa as a hard mass, as in Vegetable Ivory. The albumen may be uniform throughout, or it
late XII may present a mottled appearance, as in the Nutmeg, the
g. 11. seeds of Anonaceæ, and some Palms, where it is called *ruminated*. This mottled appearance is due to a protrusion of a dark lamella of the endopleura between folded protuberances of albumen. The endosperm within the embryo-sac is developed from the protoplasm of that sac, but in many cases as it grows inward the whole protoplasm is not converted into a solid mass, but a cavity is left in the centre which is usually filled with fluid, as in the Coco-nut. In the thickened albumen of this Palm, as well as in that of the Attalea funifera, the Date, and the Doum Palm, the small cavity in the centre and radiating spaces are well seen under the microscope. The albumen is a store of matter laid up for the nourishment of the embryo. The relative size of the embryo and of the endosperm varies much. In Monocotyledons the embryo is usually small, and the endosperm large, and the same is true in the case of Coffee and many other plants amongst Dicotyledons. The opposite is the case in other plants, as in the Labiatæ, Plumbaginaceæ, &c.

In angiosperms after fertilization the embryonal vesicle undergoes changes by which the embryo plant is eventually formed. The portion of the vesicle nearest the apex of the embryo-sac coalesces with it. The lower portion enlarges and lengthens greatly, and divides by transverse partition until a large terminal cell is formed at the extremity of a *suspensor or proembryo* (figs. 316, 317), formed of smaller cells. It is this terminal cell which immediately forms the The embryo.

Fig. 314.

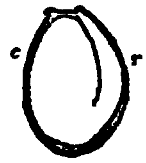

Fig. 315.

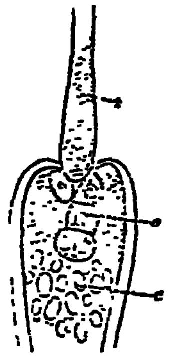

Fig. 316.

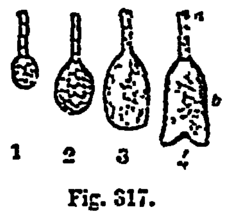

Fig. 317.

Fig. 314.—Entire anatropal seed of the Orange (*Citrus Aurantium*), with its rugose or wrinkled testa, and the raphe *r* ramifying in the thickness of the testa on one side.

Fig. 315.—Seed of Wallflower (*Cheiranthus*) cut vertically. The seed is exalbuminous or aperispermic—all the nourishing matter being incorporated with the cotyledons *c*. On removing the integument which is marked by the dark lines, the embryo alone is found in the interior. The radicle *r* is folded on the edges of the cotyledons, which are accumbent. The plant belongs to the division of Cruciferæ, called Pleurorhizeæ.

Fig. 316.—Section of the ovule of *Œnothera*, showing the pollen-tube *t*, with its enlarged extremity applied to the end of the embryo-sac, and introverting it slightly; the germinal vesicle in the sac has been impregnated, and has divided into two parts, the upper part forming a confervoid septate suspensor *s*, and the lower dividing into four parts, which form a globular mass—the rudimentary embryo, surrounded by endospermal cells *e*.

Fig. 317.—A Dicotyledonous embryo, in different stages of development, within the seed. At 1 it appears as a globular cellular mass at the extremity of a cellular cord or suspensor; at 2 it becomes more ovoid; it enlarges still more at 3; and at 4 it presents two distinct portions,—*a*, the radicle attached to the suspensor, and *b*, the two cotyledons.

embryo. By longitudinal growth the terminal cell becomes pushed into the endosperm (when present) of the sac, and becomes completely surrounded by it. In the lower part of the central cell of gymnosperms a cell is produced which divides until a proembryo is formed, which elongates and bursts through the central cell. The divisions in this proembryo take place so that several suspensors are formed, penetrating the endosperm. Usually, each of these elongates and bears a large cell at its extremity, which becomes an embryo; thus polyembryony occurs. The terminal cell of the proembryo in both angiosperms and gymnosperms increases in size, and divides repeatedly, until a cellular axis is formed. This is the rudiment of the embryo. Upon this axial mass, one, two, or more rounded cellular protuberances appear, the indications of the first leaves or cotyledons; and at the point where the embryo joins the proembryo is

the embryo, especially in Monocotyledons, and these arise as cellular processes from the outer or pericambial layer of the plerome in the hypocotyledonary portion of the axis. The primary root of the embryo is, by reason of its formation, always directed to the micropyle. In Monocotyledons and some Dicotyledons the young root rises deep in the tissues of the embryo, which, when it sprouts, form a sheath or coleorhiza around it. The lateral roots have also sheaths.

The embryo then consists of *cotyledons* (figs. 52, 53, 58, *c*), or the first leaves of the plant produced upon a cellular axial mass. To that part of this axis immediately beneath the cotyledons the terms *hypocotyledonary portion, caulicle*, or *tigellus* (*t*) have been applied, and continuous backwards with it is the young root or *radicle* (*r*), the descending axis, their point of union being the *collum*, collar, or neck. The terminal growing bud of the axis is called the *plumule* or *gemmule* (*g*), and represents the ascending axis. That extremity of the embryo which produces the first leaves or cotyledons is called the *cotyledonary* extremity of the embryo, while the opposite is the *radicular* extremity. The radicular extremity being continuous with the suspensor points towards the micropyle (fig. 318), or the summit of the nucleus, an important fact in practical botany; while the cotyledonary extremity is pointed towards the base of the nucleus or the chalaza. Hence, by ascertaining the position of the micropyle and chalaza, the two extremities of the embryo can in general be discovered. In some rare instances, in consequence of a thickening in the coats of the seed, as in Ricinus and some other Euphorbiaceæ, there is an alteration in the micropyle, so that the radicle does not point directly to it. It is in many cases difficult to recognize the parts in an embryo; thus in Cuscuta, the embryo appears as an elongated axis without divisions; and in Caryocar butyrosum, the mass of the embryo is made up by the radicular extremity and tigelle, in a groove of which the cotyledonary extremity lies embedded. In some Monocotyledonous embryos, as in Orchidaceæ, the parts of the embryo of the ripe seed are not differentiated, and only become so after germination. In parasitic plants which form no chlorophyll, as Orobanche, Monotropa, &c., the embryo remains without differentiation, consisting merely of a mass of cells until the ripening of the seed. When the embryo is surrounded by the endosperm on all sides except its radicular extremity it becomes *internal* or *intrarius;* when lying outside the endosperm, and only coming into contact with it at certain points, it is *external* or *extrarius*. When the embryo follows the direction of the axis of the seed, it is *axile* or *axial* (fig. 318), and it may be either *external*, so as to come into contact with the endosperm only by its cotyledonary apex, or *internal*. In the latter case the radicular extremity may, as in some Coniferæ, become incorporated with the endosperm apparently by means of a thickened suspensor. When the embryo is not in the direction of the axis, it becomes *abaxile* or *abaxial;* and in this case it may be either straight or curved, internal or external. In campylotropal seeds the embryo is curved, and in place of being embedded in endosperm, is frequently external to it, following the concavity of the seed (fig. 319), and becoming *peripherical*, with the chalaza situated in the curvature of the embryo, as in Caryophyllaceæ

It has been already stated that the radicle of the embryo is directed to the micropyle, and the cotyledons to the chalaza. In some cases, by the growth of the integuments, the former is turned round so as not to correspond with the apex of the nucleus, and then the embryo has the radicle directed to one side, and is called *excentric*, as is seen in Primulaceæ, Plantaginaceæ, and many Palms, especially the Date. The position of the embryo in different kinds of seeds varies. In an orthotropal seed the embryo is inverted or *antitropal*, the radicle pointing to the apex of the seed, or to the part opposite the hilum. Again, in an anatropal seed the embryo is *erect* or *homotropal* (fig. 318), the radicle being directed to the base of the seed. In some anatropal seeds, as in Castor oil, the exostome is thickened or carunculate, and the endostome does not correspond exactly to it, so that the radicle of the embryo is directed to a point a little removed from the exostome. In curved or campylotropal seeds the embryo is folded so that its radicular and cotyledonary extremities are approximated, and it becomes *amphitropal*. In this instance the seed may be exalbuminous, and the embryo may be folded on itself; or albuminous, the embryo surrounding more or less completely the endosperm, and being peripherical. According to the mode in which the seed is attached to the pericarp, the radicle may be directed upwards or downwards, or laterally, as regards the ovary. In an orthotropal seed attached to the base of the pericarp it is superior, as also in a suspended anatropal seed. In other anatropal seeds the radical is inferior. When the seed is horizontal as regards the pericarp, the radicle is either centrifugal, when it points to the outer wall of the ovary; or centripetal, when it points to the axis or inner wall of the ovary.

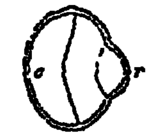

Fig. 322.

FIG. 318.—The seed of the Pansy (*Viola tricolor*) cut vertically. The embryo *pl* is axial, in the midst of fleshy albumen *al*. The seed is anatropal, and the embryo is homotropal; the cotyledons *co* point to the base of the nucleus or chalaza *ch*, while the radicle, or the other extremity of the embryo, points to the foramen, close to the hilum *h*. The hilum or base of the seed, and the chalaza or base of the nucleus are united by means of the raphe *r*.

FIG. 319.—Seed of the Red Campion (*Lychnis*), cut vertically, showing the peripherical embryo, with its two cotyledons and its radicle. The embryo is curved round the albumen, so that its cotyledons and radicle both come near the hilum. The embryo is sometimes called amphitropal.

FIG. 320.—Mature Dicotyledonous embryo of the common Almond, with one of the cotyledons removed; *r*, radicle; *t*, tigelle or caulicule; *c*, one of the cotyledons left; *tc*, cicatrix left at the place where the other cotyledon was attached; *g*, gemmule composed of several small leaves.

FIG. 321.—Transverse section of the seed of the Wallflower (*Cheiranthus*). The radicle *r* is folded on the edges of the cotyledons *c*, which are said to be accumbent.

FIG. 322.—Transverse section of the seed of the Dame's Violet (*Hesperis*) The radicle *r* is folded on the back of the cotyledons *c*, which are said to be incumbent

Plants in which there are two cotyledons produced in the embryo are *Dicotyledonous*. The form of this embryo varies much; and although sometimes resembling in its general aspect that of Monocotyledons, yet it is always distinguished by a division taking place at the cotyledonary extremity (fig. 317), by which two, more or less evident, lobes are formed. The two cotyledons thus formed are opposite to each other (figs. 58 and 320). The cotyledons are not always, however, of the same size. Thus, in a species of Hiræa, one of them is smaller than the other, and in Carapa guianensis there appears to be only one, in consequence of the intimate union which takes place between the two. The union between the cotyledonary leaves may continue after the young plant begins to germinate. Such embryos have been called *pseudo-monocotyledonous*. The texture of the cotyledons varies. They may be thick, as in the Pea (fig. 58), exhibiting only slight traces of venation, with their flat internal surfaces in contact, and their backs more or less convex; or they may be in the form of thin and delicate laminæ,

flattened on both sides, and having distinct venation, as in Ricinus, Jatropha, Euonymus, &c. In the former case they are called *fleshy*, or seminal lobes; in the latter, *foliaceous*, or seminal leaves. The cotyledons usually form the greater part of the mature embryo, and this is remarkably well seen in such exalbuminous seeds as the Bean and Pea.

Cotyledons are usually entire and sessile. But they occasionally become lobed, as in the Walnut and the Lime, where there are five lobes; or petiolate, as in Geranium molle; or auriculate, as in the Ash. Like leaves in the bud, cotyledons may be either applied directly to each other, or may be folded in various ways. In Geranium the cotyledons are twisted and doubled; in Convolvulus they are corrugated; and in the Potato and in Bunias, they are spiral,—the same terms being applied as to the foliage leaves. The radicle and cotyledons may be either straight or curved in various ways. Thus, in some Cruciferous plants, as the Wallflower, the cotyledons are applied by their faces, and the radicle (fig. 321) is folded on their edges, so as to be *lateral;* the cotyledons are here *accumbent.* In others, as the Hesperis, the cotyledons (fig. 322) are applied to each other by their faces, and the radicle, *r*, is folded on their back, so as to be *dorsal*, and the cotyledons are *incumbent.* Again, the cotyledons are *conduplicate* when the radicle is dorsal, and enclosed between their folds. In other divisions the radicle is folded in a spiral manner, and the cotyledons follow the same course.

In many gymnosperms more than two cotyledons are present, and they are arranged in a whorl. This occurs in Coniferæ, especially in the Fir (fig. 323), Spruce, and Larch, in which six, nine, twelve, and even fifteen have been observed. They are linear, and resemble in their form and mode of development the clustered or fasciculated leaves of the Larch. Plants having numerous cotyledons are occasionally denominated *polycotyledonous.* In the gymnospermous genus Welwitschia, there are two cotyledons which last throughout its life (more than a century), and in the course of time they grow to an enormous size, being sometimes six feet long and two or three feet in breadth. They constitute the only leaves of the plant. In species of Streptocarpus the cotyledons are also permanent, and act the part of leaves. One of them is frequently largely developed, while the other is small or abortive.

In those plants in which there is only a single cotyledon (fig. 53) in the embryo, hence called *Monocotyledonous*, the embryo usually has a cylindrical form more or less rounded at the extremities, or elongated and fusiform, often oblique. The axis is usually very short compared with the cotyledon, which in general encloses the plumule by its lower portion, and exhibits on one side a small slit which indicates the union of the edges of the vaginal or sheathing portion of the leaf (fig. 324). In Grasses, by the enlargement of the embryo in a particular direction, the endosperm is pushed on one side, and thus the embryo comes to lie outside at the base of the endosperm. The lamina of the cotyledon is not developed. Upon the side of the embryo next the endosperm and enveloping it is a large shield-shaped body, termed the *scutellum.* This is by some authors considered to be an outgrowth from the hypocotyledonary portion of the axis or expansion of the radicular extremity, enveloping more or less the cotyledon and plumule, in some cases, as in Maize, completely investing it; in other cases, as in Rice, merely sending small prolongations over its anterior face at the apex. By others this scutellum is considered as the true cotyledon, and the sheathing structure covering the plumule is regarded as a ligule or axillary stipule. In several other Monocotyledonous plants, as Ruppia and Zostera, this scutellar structure is well seen, and in these cases its homology, as an expansion of the radicular extremity of the embryo, is clearly discernible; and this is further borne out by such cases as that of Caryocar butyrosum among Dicotyledons, where the radicular swelling occupies most of the embryo (fig. 326). In some Grasses, as Oats and Rice, a projection

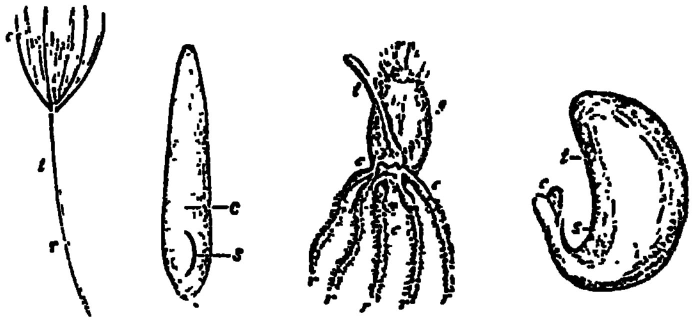

Fig. 323. Fig. 324. Fig. 325. Fig. 326.

Fig. 323.—Polycotyledonous embryo of the Pine (*Pinus*) beginning to sprout. The axis *t* shows its radicular portion *r* and cotyledonary portion *c*. The cotyledons *c* are numerous. Within the cotyledons the primordial leaves are seen, constituting the plumule or first bud of the plant.

Fig. 324.—Embryo of a species of Arrow-grass (*Triglochin Barrelieri*), showing a uniform conical mass, with a slit *s* near the lower part. The cotyledon *c* envelops the young bud, which protrudes at the slit during germination. The radicle is developed from the lower part of the axis *r*.

Fig. 325.—Grain of Wheat (*Triticum*) germinating. The embryo lies at one side of the grain *g*. The radicular portion of the embryo gives off rootlets *r r r r r* covered with cellular hairs. The principal root is the central one; the others being developed subsequently in succession. The roots pass through sheaths *c c c*. The ascending axis *t*, sheathed in the cotyledon, rises upwards.

Fig. 326.—Embryo of *Caryocar butyrosum*. *t*, thick tigelle or caulicule, forming nearly the whole mass, becoming narrowed and curved at its extremity, and applied to the groove *s*. In the figure this narrowed portion is slightly separated from the groove; *c*, two rudimentary cotyledons.

of cellular tissue is seen upon the side of the embryo opposite to the scutellum, that is, on the anterior side. This has been termed the *epiblast*. It is very large in Rice. This by some was considered the rudimentary second cotyledon; but this is impossible, as it arises outside, and after the first cotyledon. It is merely an outgrowth of the radicular extremity like the scutellum. The radicular portion of the axis is usually shorter than the cotyledon, and more dense in structure; but in some instances it becomes much larger, giving rise to what has been called a *macropodous* embryo.

5. *Female Organs and Reproduction in Cryptogams.*

Female organs in higher Cryptogams.

The female organs of reproduction, like the male organs, have not been demonstrated in all Cryptogams. In all vascular Cryptogams, and in Mosses and Hepaticæ, certain usually flask-shaped bodies, which have been termed *archegonia* or *pistillidia* (fig. 327), represent the female organs producing cells or spores, which germinate and form new plants (fig. 54). These archegonia have the general structure of a large cell, the *central cell* or *oosphere* (*c*) surrounded by a layer of smaller cells. From the apex of this oosphere leads a canal, which is bounded by four rows of small cells and constitutes the *neck*, and in it is a large cell full of soft mucilaginous matter, which has been formed from the central cell, and is the *canal cell*. Upon the wall of the oosphere, turned towards the neck, a small portion different from the surrounding part is the *receptive spot*. Fertilization is effected by the antherozoids freed from the antheridium, penetrating the neck of the archegonium, and eventually reaching the receptive spot of the central cell or oosphere; they then enter the oosphere and coalesce with it. The fertilized oosphere is termed an *oospore*, and it then may escape from the archegonium, and sooner or later germinates; or it germinates within the archegonial cells. These archegonia are, in vascular Cryptogams, produced upon a cellular expansion formed generally from a spore, and termed the *prothallus* (fig. 245), which is of varying size and form. Both archegonia and antheridia may be formed on one prothallus, or only one form of organ may be produced, thus indicating a tendency to diclinism.

In Characeæ the female organ has a peculiar structure.

In Characeæ. and is termed a *nucule* (fig. 240, *n*). This consists of a large *central cell*, of which the contents at the apex are clear and hyaline, while the lower part contains much starch and fat. Rising from its base and twisting round it are five long tubes (fig. 328), at the extremity of each of which

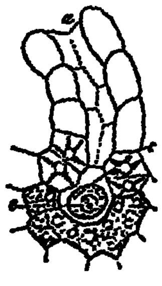

Fig. 327.

Fig. 328.

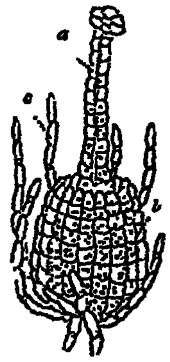

Fig. 329.

FIG. 327.—Archegonium of the Forked Spleenwort (*Asplenium septentrionale*) immediately after fertilization. *a*, canal leading to the large cell (oosphere) *c* at the base of the archegonium; *c*, nucleated embryonic cell, whence the sporangiferous frond proceeds.
FIG. 328.—Nucule of Chara entire, with five cells, wound round a large central cell in a spiral manner; *a*, crown or coronula of five smaller cells.
FIG. 329.—Pistillidium of Liverwort (*Marchantia*). It is a cellular body surrounded by an involucre (perigone or calyx) *b*, and septate filaments (paraphyses) *c*, and it is provided with a styloid calyptra *a*.

above the apex of the central cell is a single short cell in Chara, while in Nitella it is divided transversely into two. These five or ten short cells form the *crown*. They unite together so that their apices project as small teeth. Between the crown and the apex of the central cell, which is termed the *apical papilla*, a cavity is included, bounded at the sides by the five enveloping tubes, which at this point form the *neck* of the nucule. The cavity of the neck is constricted in the middle by the projection inwards of the tubes to form a sort of diaphragm, so that the enclosed cavity has a rude hour-glass-like shape, the upper cavity closed above by the crown being connected by a narrow canal with a lower cavity bounded beneath by the apical papilla of the central cell. When fertilization takes place slits are formed betwixt the five tubes of the neck, beneath the crown and above the diaphragm. The antherozoids from the globule enter by them into the upper cavity, pass through the canal into the lower one, and fuse with the apical papilla of the central cell or oosphere. The oospore thus formed becomes detached from the plant, being covered by the thickened inner wall of the tube which invested it. The nucule rises from the base of one of the whorl leaves in Chara, and is therefore above the globule; in Nitella it is produced upon the leafy axis beneath the globule.

In Mosses and Hepaticæ. In Mosses the archegonia are frequently situated along with the antheridia and paraphyses. They are surrounded by the same whorl of leaves, or *perichætium*, when the moss is said to be hermaphrodite, or they occur separately on the same or on different plants, the moss being then monœcious or diœcious. The term *perigone* is applied to the whorl of leaves around the antheridia. The basal portion of the archegonia which surrounds the oosphere is termed the *epigone*. In Hepaticæ the archegonia (fig. 329) are situated in the substance of the thallus itself, or they may be in various situations, as in Jungermannia (fig. 330); in Marchantia they are produced upon the under surface of a stalked stellate disk (fig. 331).

In Thallogens. In many Thallogens no structure analogous to a female organ has been as yet discovered; in some, however, such structures have been met with. Thus amongst Algæ large cells, termed *oogonia*, are found, in which usually one, sometimes many (Fucaceæ), oospheres are produced (fig. 332). The antherozoids from the antheridium fertilize these, penetrating the oogonia at a definite point thinner than the surrounding portion; and oospores are formed. In the Florideæ, a group of Algæ, *the organs are different* in character. Here the antherozoids are *not motile*, having no cilia. On discharge from the antheridium, these are washed into a long filiform hollow body, termed the *trichogynium*. This is supported usually upon a cellular stalk—the *trichophore*—at the side of the base of which is a small cellular mass. The antherozoids having entered the trichogynium, fertilization is effected, and results in the formation, from the cellular mass at the base of the

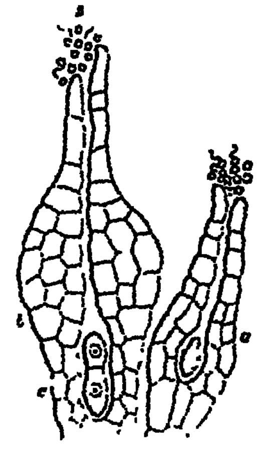

Fig. 330.

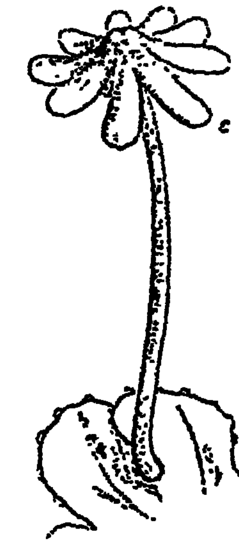

Fig. 331.

FIG. 330.—Archegonia of *Jungermannia bicuspidata*. *a*, archegonium, with a tube leading to a cavity near the base of which is a cell; *b*, archegonium after fertilization, with the cell *c* divided into two nucleated portions. This double nucleated body is the rudiment of the fruit-bearing stalk. At the apex of the canal leading to the cell are seen spermatozoids *s s*.
FIG. 331.—Thallus of Liverwort (*Marchantia polymorpha*), bearing a stalked fruit *s*, which is the product of the impregnated cell of the archegonium. The receptacle at the apex of the stalk bears on its under surface sporangia containing spores and elaters. The spores, when germinating, produce a thallus, on which antheridia and archegonia are formed.

trichophore, of a large cell, the *cystocarp*, in which spores are formed. In the Saprolegnieæ the antheridia actually penetrate into the oogonium and discharge their antherozoids. Amongst Fungi it is rare to find sexual organs. In some thecasporous fungi, as Eurotium, a sexual process has been observed. The female organ, here termed *ascogonium* or *carpogonium*, is of a spiral elongated character, immediately surrounding which are the antheridia,

Fig. 332.

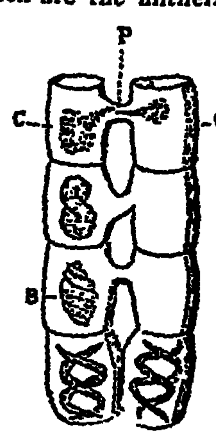

Fig. 333.

FIG. 332.—Transverse section of a conceptacle of a Seaweed (*Fucus vesiculosus*), showing the spores in the coverings, *p*, and paraphyses lining the cavity. The spores escape by an orifice *o*.
FIG. 333.—Two filaments of a Confervaceous Alga (*Zygnema*), conjugating, *i.e.*, uniting together by tubes *p*, which pass between the different cells. The contents of two cells *c c* unite so as to form a germinating spore *s*. In the lower two cells spiral filaments are seen.

few in number, which open into the apex of the female organ, and discharge their antherozoids. The result is the formation of cellular tissue round the ascogonium, forming what is termed a *perithecium*, and within the ascogonium large cells (*asci*) are produced, in which spores

or sporidia are subsequently developed. In Lichens no sexual organs have as yet been clearly demonstrated.

Amongst Fungi and Lichens there are certain bodies to be noted, which may be connected with sexual reproduction, but the function of which is at present unknown. Embedded in the margin of the thallus in Lichens and on various parts of the plant in Fungi, certain hollow urn-shaped bodies are found, which have been termed *spermagones* (conceptacles) (fig. 334). These are usually closed all but a small opening at the apex. From their base rise peg-shaped projections or *sterigmata* (fig. 335), bearing at

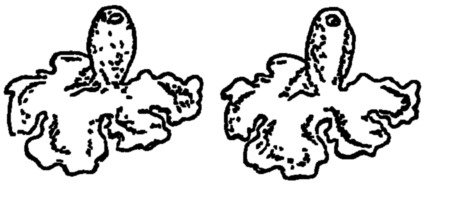

Fig. 334.

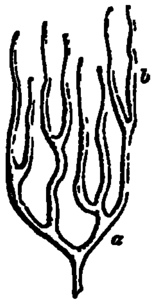

Fig. 335.

FIG. 334.—Two spermagones on thalli of Lichens.
FIG. 335.—Sterigmata *a* and spermatia *b* of *Cladonia fimbriata*.

their summit elongated, sometimes curved, bodies, termed *spermatia*, which, when mature, are discharged through the apex of the spermagone. These are by some considered the analogues of the antherozoids in other Cryptogams. There are also found other conceptacles, to which the name of *pycnidia* or *pycnides* is given. These contain large spores, which have been termed *stylospores* (fig. 336), but their homology is at present unknown.

Another process of reproduction is seen amongst Cryptogams. This is termed *conjugation* (fig. 333). It differs from the process of fertilization just described in that it consists of a union of the contents of two similar cells, whilst fertilization essentially consists in the mutual influence of dissimilar cells. It is well seen in many Algæ, such as Diatoms, Volvocineæ, Conjugatæ, also in some Fungi, such as species of Rhizopus and Zyzygites. It may consist in the coming together of two cells,—either moving spores, as in Pandorinia, or motionless, as in Diatoms,—which completely fuse, and a compound spore, or *zygospore*, results; or prolongations of the wall of two adjacent cells meet, the partition between the two gives way and the contents from the one pass into the other, and a zygospore is formed, as in Zygnema. Zygospores germinate only after a long period of rest.

Amongst Thallogens especially, though it also occurs in other Cryptogams, the asexual mode of reproduction is very common. But the manner of formation and the nature of the spores is diversified.

Amongst Algæ two modes of asexual reproduction are seen,—by motile spores and by motionless or resting spores. In the former case the contents of a cell form a new cell, which escapes from the mother-cell, and moves about by means of cilia, which are formed either all round it, as in Vaucheria (fig. 337), or as a tuft at one end, as in Œdogonium. These are termed *swarm spores*, or *zoospores*, and frequently are of different sizes, being termed respectively *microgonidia* and *macrogonidia*. After swimming about for a time they fix themselves, and develop small rhizoids from one extremity, the other growing up into the plant. The motionless spores are seen in the Florideæ, where they are formed in cells, four in each, attached together in a row, or as a tetrahedron, constituting the *tetraspore* (fig. 338).

Amongst Fungi asexual reproduction is very common. Swarm spores are rarely formed; but the mode of formation of motionless spores is very various. They may be produced in the interior of distinct sacs called

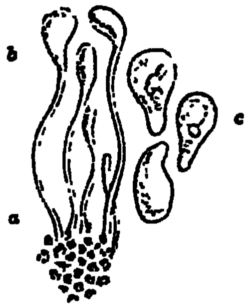

Fig. 336.

Fig. 337.

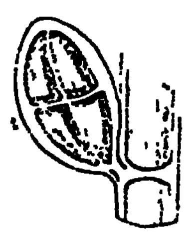

Fig. 338.

FIG. 336.—Basidia *a*, stylospores *b*, free stylospores *c*, from pycnides of Lecidia.

thecæ, *asci*, or *cystidia* (fig. 339), when they are denominated *endospores* or *ascospores*, and the plants are said to be *thecasporous* or *ascosporous*. When they are developed on the exterior of sacs called *basidia* (fig. 340), they are denominated *exospores*, and the plants are *basidiosporous*.

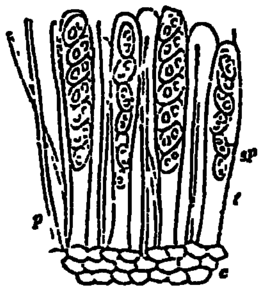

Fig. 339.

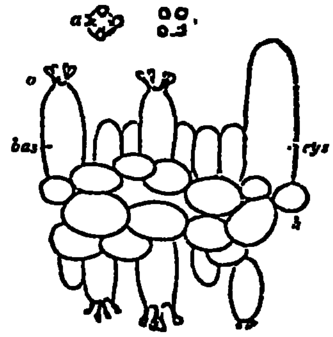

Fig. 340.

FIG. 339.—Vertical section of the fructification of a Fungus (*Peziza*), showing cellules *c*, bearing clavate spore-cases or thecæ *t*, which contain nucleated cells *sp*. These cells become sporidia, containing spores. Along with the thecæ are cellular filaments or paraphyses.
FIG. 340.—Portion of a lamella or gill of the Mushroom (*Agaricus campestris*), cut transversely, showing the two lateral surfaces bearing basidia *bas*, with four spores *spo* at their apices, and cystidia *cys* or sacs containing minute cells. The hymenium is marked *h*. At *a* and *b* are represented the four spores.

When produced in the midst of a gelatinous mass, without any evident differentiation, they are called *myxospores*, the plants being *myxosporous*. Both the endospores and the exospores may by division become *septate*, and form *compound spores*, each of the secondary spores so formed being termed a *merispore*. Four or eight basidiospores are usually produced from each basidium. In the asci numerous spores are formed. Other forms of spores seen in Fungi are the *conidia*. These are stalked spores which arise from a mycelium.

In Lichens we find asci which produce spores or sporidia just as in Fungi; and in addition there also exist spermogones with their sterigmata and spermatia as well as pycnides and stylospores. Besides the spores there are organs called *soredia* in Lichens. These are groups of small round cells or *gonidia* (fig. 97), surrounded by hyphæ, which are capable of independent growth after removal from the thallus. These gonidia are now regarded by many as an Alga, upon which the hypha, which is supposed to be an ascomycetous Fungus, is parasitic.

In Chara a curious mode of asexual reproduction is seen which presents several well-marked modifications, the process always proceeding at the nodes, and consisting in the growth of a new axis from a nodal cell either isolated or united with other cells.

In all vascular Cryptogams, Muscineæ, and many Thallo
lo
fe
or
is

In Ferns. Amongst Ferns the oospore germinates and produces an asexual generation. The embryo plant formed from this spore is a simple mass of cellular tissue, no cotyledons being formed. This, then, is an *Acotyledonous* embryo (fig. 54). The same happens in other vascular Cryptogams, which are therefore also Acotyledonous. The embryo so formed has a primary meristem, with an apical cell, by division of which it increases in size,—roots being formed downwards and a leaf-bearing axis upwards, upon which, eventually, the *fructification* (fig. 341) is formed. This consists in Ferns of the production of either stalked or sessile spore-cases or *sporangia*, from the epidermis on the back (Aspidium) or edges (Pteris) of a leaf (frond), or upon a special branching axis (Osmunda), or a spicate one (Ophioglossum). These, when situated on the frond, are arranged in definite clusters or *sori* (fig. 342), either

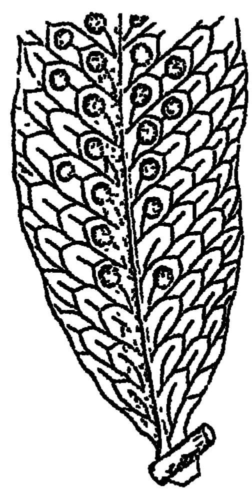

Fig. 341.

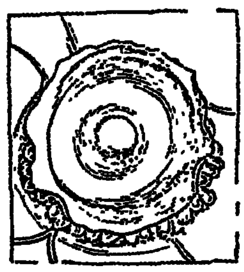

Fig. 342.

FIG. 341.—Frond (fructiferous leaf) of a Fern (*Niphobolus*), showing sori, or round clusters of sporangia at the ends of veins. As these sori are on the back of the frond, the Fern is called dorsiferous.

FIG. 342.—Sorus or cluster of sporangia of a Fern (*Aspidium trifoliatum*). The sporangia are covered by an indusium or involucre, derived from the epidermis of the frond. The involucre is round (orbicular), and attached by its centre in an umbilical manner. The annulate sporangia are seen at the lower edge of the involucre.

rounded or elongated. With the sporangia are usually associated jointed cells or *paraphyses*. Frequently the sori are covered by a thin cellular layer forming an *indusium* or involucre, or the margin of the frond folds over them, forming a false indusium. Within the sporangium spores are produced, and when ripe these escape by the rupture of the sporangium, this in many cases being provided for by the formation, at a definite point, of an *annulus* or ring (fig. 343) of unequally thickened cells. Hence some Ferns are *annulate*, others *exannulate*. The cell-wall of each spore is divisible into an outer layer or *exospore*, and an inner or *endospore*. When the spore reaches the soil it germinates, and after a longer or shorter period produces the sexual generation. In this process the variously marked exospore is ruptured by the enlarging endospore, which divides so as eventually to form a flattened cellular expansion or *prothallus* (fig. 344) with small cellular *rhizoids*. Upon this, usually on the under surface, the sexual organs, consisting of antheridia and archegonia, are produced. A tendency to *diœcism* is observed in prothalli, frequently producing only one kind of sexual organs. By the mutual influence of those sexual organs an oospore is formed, from which a new asexual generation arises. Thus in Ferns the alternation consists of two dissimilar generations,—a sexual or prothallial generation, and an asexual generation.

In Equisetaceæ. In Equisetaceæ the same alternation of two dissimilar generations occurs. Upon an asexual generation the fructification is formed at the apex of a leaf-bearing axis. Peltate hexagonal stalked scales (fig. 345) are arranged in close whorls round the apex of the axis, forming a pyramidal head (fig. 346, *f*), the surface of the scales being

opens towards the stalk of the scale, and the spores are shed, each having attached to it four clavate filaments sometimes

termed *elaters* (fig. 3), which are very hygroscopic. By germination of these spores a sexual generation or prothallus is formed.

opo-. In Lycopodiaceæ a sexual process has not been observed in all genera; but in Selaginella and Isoetes, where it has been observed, it is exceedingly instructive, as it forms a connecting link between the process as seen in Cryptogams and that observed in Angiosperms. The asexual generation produces the fructification which consists in the formation of a single sporangium in the axil of each leaf of a certain part of the axis. In those genera in which sexual organs have been discovered these sporangia are of two sizes, termed *macrosporangia* (fig. 347) and *microsporangia* respectively. The whole fructification frequently forms a spike. In the *macrosporangium* or *oophoridium* few, usually four, large spores (*macrospores*) are formed, having each an exospore and an endospore. In the microsporangium (fig. 248) numerous small spores or microspores are formed of a similar structure. When the sporangia are shed the capsule decays, and the spores escape. Within the endospore of the macrospore, a development of cellular tissue takes place which eventually completely fills it and constitutes the *prothallus*, termed sometimes on this account *endothallus* (fig. 348). As it increases in size the exospore is ruptured triradiately, and the endospore projecting is also ruptured, and thus the prothallus is protruded, in the substance of which archegonia are formed. The microspores, on the other hand, produce within their endospore, sometimes after the formation of a rudimentary prothallus, antherozoid mother-cells, which are discharged by the rupture of the exospore and endospore (fig. 249). By fertilization of the oosphere of the archegonium an oospore is formed, from which the sexual generation arises. The embryo is formed from the lower part of the oospore, the upper half elongates and forms a *suspensor* (fig. 349) of several cells, by which the embryo is pushed downwards into the substance of the prothallium, and there develops into a young plant, rudimentary cotyledons being formed upon the young axis. It will be observed that this process resembles very much the mode of embryogeny in Phanerogams, and, indeed, from this it is but a step to the form found in Gymnosperms and thence to Phanerogams.

In Rhizocarpeæ. In Rhizocarps the sporangia are formed in the interior of ovoid sacs, termed *sporocarps* (fig. 350), which are usually supported on stalks, and rise from the leaves near their base, one or many on the same stalk. In each sporocarp, microsporangia and macrosporangia are formed in various positions; and a prothallium (fig. 351) is formed in the macrospore, as in Lycopodiaceæ. From the oospores formed in it the embryos are produced, but without suspensors.

In Characeæ. In Characeæ there is an alternation of a sexual with an asexual condition. From the oospore a small proembryo is first formed, from a cell of which the sexual plant is developed.

In Mosses. In Mosses the sexual generations are produced as lateral shoots from a filamentous *proembryo* or *protonema* (fig. 352). Upon this leaf-bearing axis either at the apex (acrocarpous) or laterally (pleurocarpous) the sexual organs arise. The asexual generation rises from the oospore and constitutes what is usually termed the *fruit* (fig. 353) of the moss. It has been designated the *sporogonium*. The sporogonium is formed by the enlargement of the oospore into an ovoid embryo which presses against the epigone, finally rupturing it, and carries the upper portion upwards with it as the *calyptra* or cap, the lower portion forming a sheath or *vaginula* at the base. This calyptra may be either split on one side, *dimidiate*, or entire, then termed *mitriform*. The upper part of the sporogonium forms a *capsule*, *urn*, or *theca*; the lower portion acts as a supporting stalk or *seta*, which is often swollen, just beneath the capsule forming the *apophysis* (fig. 354, *a*). In Sphagnum the sporogonium is fully developed within the epigonal leaves, and when complete the axis beneath it elongates, forming the *pseudopodium*, and projects considerably beyond the perichætium. The walls of the capsule of the sporogonium consist of several layers of cells. It has a central axis or *columella*, surrounding which are the *spores*. When mature the capsule usually dehisces,

FIG. 353.—Hygrometric Cord-Moss (*Funaria hygrometrica*), with its urn-like thecæ *u* supported on stalks *p*, which arise from perichætial leaves *f*. The thecæ are covered by a calyptra *c*, which splits on one side. The opercular or lid *o* is seen in one of the thecæ from which the calyptra has fallen. The seta is twisted, and displays hygrometric properties.

either by four longitudinal valves, as in Andræa, or most commonly by a lid or *operculum* (fig. 355), between which and the capsule an *annulus* or ring of cells is separated. On removal of the operculum the stoma or opening of the capsule is seen. The margin of this is sometimes entire (*gymnostomi*), more usually fringed with *teeth* or cellular prolongations, constituting a *peristome* (fig. 355, *p*), either in one row (*aploperistomi*) or in two rows (*diploperistomi*). Stretching across the mouth of the capsule is frequently seen a thin cellular membrane, the *epiphragm* or

tympanum, as in Polytrichum. The spores shed from the capsule germinate and give rise to the proembryo which by budding gives off the sexual plants.

In Hep-. In Hepaticæ the sexual generation arises either directly [illegible]

from the spore of the asexual generation, or a small pro-embryo is first formed. The *sporogonium* is of various forms, and originates differently in different groups from the oospore. It is always formed within a cellular covering or epigone. In Anthoceros the sporogonia are elongated and open by two valves, and there is a central cellular columella. In Jungermannia the sporogonia are globular, and open by four spreading valves. There is no central column, but the inner wall displays cellules, called *elaters*, fixed by one extremity, and containing one or two spiral fibres which by their elasticity scatter the spores. In Riccia the sporogonia are globular, and there are neither elaters nor columella.

In Fungi. Very little is known of the sexual reproduction of Fungi, and regarding the alternation of sexual and asexual generations in them. But we have abundant instances of alternation amongst the asexual generations, and along with this of that curious phenomenon included under the term *heterœcism*, which consists in the growth of one generation of a parasitic Fungus upon one host, and the development of another generation upon a different host. By tracing out this phenomenon, many forms, described formerly as distinct species, are now shown to be generations of one and the same Fungus. The asexual spores of Fungi are produced upon certain structures which have been frequently termed the *fructification*. For instance, in basidiosporous Fungi the collection of basidia forming the *hymenium* is usually situated on large receptacles. The structure commonly known as a *fungus* (fig. 356) is a receptacle produced upon a *mycelium* (*my*). In its young state it appears as a tubercle upon the mycelium covered by a *volva* (fig. 356, *vol*), or wrapper, which it bursts during growth. It consists of a *pileus* or cap (*p*), at the extremity of a stalk, the *stipe* (*st*). On the under surface of the pileus are the *lamellæ* (*la*) or *gills*, of various forms, which constitute the hymenial (*hy*) layer, to which the spores are attached. At first the hymenium is covered by a veil or *indusium*, which during the growth of the stipe is ruptured, the base remaining on the stipe as the *annulus* (*an*) or ring. When, as in the Mushroom, the hymenium is exposed, the fungus is said to be *gymnocarpous* (fig. 356). In other cases, as in Phalloideæ, it is covered over by a *peridium*, and the whole mass so enclosed is the *gleba*, and the fungus is *angiocarpous* (fig. 357). In ascosporous Fungi, as Sphæria, the asci are usually formed within small roundish receptacles, termed *perithecia*; and along with the asci are usually numerous abortive filaments or paraphyses. Sometimes these perithecia are situated upon cushions or branching masses of tissue, the *stroma*. In the myxosporous Fungi the *plasmodium*, or whole protoplasmic mass of the plant, forms receptacles, in each of which is a *capillitium*, or network of fine filaments, in the interstices of which are numerous spores.

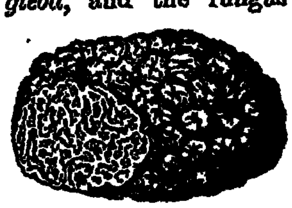

Fig. 357.

The Truffle (*Tuber cibarium*), a subterranean Fungus, with a black tuberculated or warty external covering, and a white cellular interior containing sporiferous cells.

In Lichens spores are formed in asci, which are arranged along with paraphyses, forming a hymenium in receptacles situated on the thallus, and termed *apothecia* or *lirellæ*, which are sometimes (fig. 95) supported on a stalk or *podetium*. The hyphæ, from which the asci arise, form a layer immediately beneath the hymenium, termed the *subhymenial* layer, the thick mass of hyphæ beneath being the *hypothecium*. The outermost layer of the tissue of the apothecium is termed the *excipulum*. In Lich.

Amongst Algæ alternation of generations is very common; and here, as in the case of Fungi, it may pass through several generations before reaching the original form. This is well seen in Diatoms, also in Œdogonieæ, where three generations are passed through, and in Coleochæte, where there are four dissimilar generations,—sexual and various forms of asexual reproduction alternating. In Algæ.

Explanation of the Plates.

Plate I. Papaver Rhœas, Common Red Poppy, belonging to the Nat. Ord. Papaveraceæ. The leaves are pinnatifid, the peduncles have spreading hairs, the calyx consists of 2 caducous sepals, enclosing 4 crumpled petals, the stamens are indefinite and hypogynous, and the ovary is surmounted by a radiating stigma.

Fig. 1. Stamens inserted on the thalamus, below the ovary with its sessile stigma. Fig. 2. Capsule opening by pores below the sessile radiating stigmas.

Plate II. Janipha Manihot and Eschscholtzia californica.

Fig. 1. Janipha Manihot, Cassava plant, belonging to the Nat. Ord. Euphorbiaceæ. The leaves are digitately-partite, and the flowers are in racemose cymes. Fig. 2. Racemose cyme, with a pentacoccous capsule, which separates in an elastic manner into 5 single-seeded carpels. The cyme bears male as well as female flowers. Fig. 3. Pistil with stigma. Fig. 4. Stamens and fleshy disk. Fig. 5. Seed with strophiole.

Fig. 6. Eschscholtzia californica (*nat. size*), belonging to the Nat. Ord. Papaveraceæ. It has a peculiar caducous calyx like a candle-extinguisher, and a tetrapetalous corolla, with numerous hypogynous stamens. Fig. 7. Hollowed end of the peduncle, with the pistil. Fig. 8. Section of ovary, with numerous seeds attached to 2 parietal placentas. Fig. 9. Ceratium or siliquæform capsule (*nat. size*), opening by 2 valves. Fig. 10. Section of the seed, with the Dicotyledonous embryo, which is shown separately in fig. 11.

Plate III. Malva sylvestris, Common Mallow, belonging to the Nat. Ord. Malvaceæ. The leaves have 5 lobes, the inflorescence consists of cymose fascicles, and the æstivation is contortive.

Fig. 1. Calyx with a three-leaved epicalyx or involucre. Fig. 2. Obcordate petal, with monadelphous stamens. Fig. 3. Tube of stamens formed by union of the filaments. Fig. 4. Pistil with numerous carpels and styles. Fig. 5. Stamen with reniform anther opening round the margin. Fig. 6. Section of ovary composed of numerous carpels.

Plate IV. Anacardium occidentale, Cashew-nut plant, belonging to the Nat. Ord. Anacardiaceæ.

Fig. 1. Branch (*somewhat reduced*), bearing flowers and fruit. The flowers are in cymes, and the peduncles are enlarged in a pear-like form, bearing the nut (the true fruit) at their apex. Fig. 2. Flower not expanded. Fig. 3. Flower expanded. Fig. 4. Stamen and pistil, with the calyx; one fertile stamen longer than the others. Fig. 5. Stamen separated. Fig. 6. Nut constituting the fruit. Fig. 7. Nut opened longitudinally. Fig. 8. Seed separated from the nut. Fig. 9. Cotyledons opened to show the radicle *a*, and the plumule.

Plate V. Sarothamnus scoparius, Common Broom, belonging to the Nat. Ord. Leguminosæ or Fabaceæ, Sub-ord. Papilionaceæ. The angled branches bear ternate leaves, papilionaceous flowers, and legumes.

Fig. 1. Two-lipped calyx. Fig. 2. Broadly ovate vexillum or standard. Fig. 3. One of the alæ or wings of the corolla. Fig. 4. Carina or keel. Fig. 5. Monadelphous stamens. Fig. 6. Hairy ovary with the long style, thickened upwards, and spirally curved. Fig. 7. Legume or pod.

Plate VI. Carica Papaya and Andromeda hypnoides.

Fig. 1. Carica Papaya, the Papaw tree (*much reduced*), belonging to the Nat. Ord. Papayaceæ. The leaves are palmately-cleft, and the flowers unisexual. Fig. 2. Portion of a racemose cyme of infundibuliform male flowers, with united petals. Fig. 3. Gamopetalous male flower cut open, showing the ten epicorolline stamens alternately shorter. Fig. 4. Stamen. Fig. 5. Female flowers with a deeply-5-parted corolla.

Fig. 6. Andromeda hypnoides (*nat. size*), belonging to the Nat. Ord. Ericaceæ. Fig. 7. Flower of Andromeda, with 5-parted calyx, and gamopetalous campanulate corolla. Fig. 8. Back view of stamen with its 2-horned anther. Fig. 9. Front view of stamen with bicornute and biporose anther. Fig. 10. Pistil with its ovate acuminate style. Fig. 11. Capsule, 5-celled, with a central 5-lobed placenta.

Plate VII. Œnanthe crocata, Hemlock Water-Dropwort, belonging

an obsolete limb, an irregular sympetalous corolla, exserted stamens, and 1 style. Fig. 2. Pistil separated, with ovary, style, and stigma. Fig. 3. Monospermal fruit, with the persistent pappose limb of the calyx.

Plate IX. Leontodon Taraxacum, Common Dandelion, belonging to the Nat. Ord. Compositæ, Sub-ord. Cichoraceæ. The leaves are radical and runcinate, the flowers ligulate, and arranged in capitula. The outer phyllaries (involucral leaves) are reflexed.

Fig. 1. Capitulum with reflexed phyllaries and ligulate flowers. Fig. 2. A single flower, with inferior achene (cypsela), stipitate pappus, a ligulate corolla, 5 stamens united by their anthers, and 1 style with 2 stigmas. Fig. 3. Receptacle, become dry and convex, with deflexed phyllaries. Fig. 4. Linear-obovate achene.

Plate X. Cuscuta verrucosa, Warty Dodder, belonging to the Nat. Ord. Cuscutaceæ, which is often considered as a sub-order of Convolvulaceæ.

Fig. 1. Leafless flowering stem of Dodder (*nat. size*), turning from right to left (contrary to the motion of the sun). Fig. 2. Campanulate corolla, with 5 epicorolline stamens and alternating scales. Fig. 3. Persistent calyx. Fig. 4. Capsule opening transversely near the base. Fig. 5. Dissepiment and 2 seeds. Fig. 6. Bilocular capsule cut transversely, showing 2 seeds in each loculament. Fig. 7. Roundish compressed seed. Fig. 8. Seed cut longitudinally, showing the perisperm with the spirally-rolled-up embryo.

Plate XI. Digitalis purpurea, Purple Foxglove, belonging to the Nat. Ord. Scrophulariaceæ.

Fig 1. Calyx in 5 deep segments, with the pistil. Fig. 2. Pistil separated. Fig. 3. Didynamous stamens. Fig. 4. Stamens, with the anther-lobes collateral and unopened. Fig. 5. Capsule cut transversely, showing two loculaments.

Plate XII. Myristica moschata, the Nutmeg-tree, belonging to the Nat. Ord. Myristicaceæ.

Fig. 1. Male plant (*nat. size*) with oblong nearly elliptical leaves, and flowers in axillary umbellate cymes. Fig. 2. Perianth of male plant laid open to show the stamens with their united filaments. Fig. 3. Anther, bilocular, and opening longitudinally. Fig. 4. Female flower cut open, showing the single pistil, with short style and 2-lobed stigma. Fig. 5. Young fruit. Fig. 6. Ripe drupaceous fruit in the act of bursting, and showing the mace or arillode. Fig. 7. Section of the ripe fruit. Fig. 8. The nut, consisting of a hard endocarp enclosing the seed. Fig. 9. The oval seed. Fig. 10. The seed cut vertically. Fig. 11. Vertical section of endocarp and seed, showing ruminate perisperm and the embryo. Fig. 12. Embryo, showing 2 large foliaceous plicate cotyledons. Fig. 13. Embryo with radicle and cotyledons.

Plate XIII. Euphorbia hypericifolia, Tutsan-leaved Spurge, belonging to the Nat. Ord. Euphorbiaceæ.

Fig. 1. Plant (*nat. size*) with opposite oblong leaves, and flowers in corymbose cymes. Fig. 2. Involucre with appendages, enclosing male and female flowers. Fig. 3. Involucre cut open, to show the insertion of the numerous achlamydeous male monandrous flowers, and the single naked female flower, all pedicellated. Fig. 4. Involucre deprived of its petaloid appendages, with female flower showing forked styles. Fig. 5. Involucre enclosing the ripe fruit (regma). Fig. 6. Stamen. Fig. 7. Fruit with one of the cocci separated from the columella. Fig. 8. Seed. Fig. 9. Seed cut open, showing fleshy perisperm and inverted embryo.

Plate XIV. Artocarpus incisa, the Bread-fruit tree, belonging to the Nat. Ord. Artocarpaceæ.

Fig 1. Branch reduced to 1/3rd its natural size, with cuneate-ovate pinnatifid leaves, male flowers in a club-shaped deciduous catkin, female flowers in rounded clusters. Fig. 2. Transverse section of the male amentum with numerous flowers. Fig. 3. Male flowers. Fig. 4. Single male flower separated, with a perianth in 2 segments and a single stamen. Fig. 5. Female flowers. Fig. 6. Single female flower separated, with ovary, style, and bifid stigma. Fig. 7. Ovary. Fig. 8. Ovary laid open to show the ovule. Fig. 9. A variety of the ovary with 2 loculaments. Fig. 10. Transverse section of a bilocular ovary.

Plate XV. Cycas circinalis, a species of false Sago-plant, belonging

BOTANY BAY, an inlet on the eastern coast of Australia, to the S. of the city of Sydney, in the Cumberland district of New South Wales, in 34° S. lat. and 151° 15′ E. long. In was first visited by Captain Cook in 1770, and received its name from Joseph Banks, the botanist of the expedition, on account of the variety of its flora. When, on the revolt of the New England colonies, the convict establishments in America were no longer available, the attention of the British Government, then under the leadership of Pitt, was turned to Botany Bay; and in 1787 Commodore Phillip was commissioned to form a penal settlement there. Finding, on his arrival, however, that the locality was ill-suited for such a purpose, he removed northwards to the site of the present city of Sydney. The name of Botany Bay seems to have struck the popular fancy, and continued to be used in a general way for any convict establishment in Australia. The transportation of criminals to New South Wales was discontinued in 1840.

BOTHNIA, an ancient province of Sweden, which was divided into East and West by the gulf of the same name. The eastern division, which was bounded on the N. by Lapland, E. by Archangel and Olonetz, and S. by Finland, is now incorporated with the last-mentioned district, having been ceded to Russia in 1809. The western division now forms part of the Swedish province of Norrland, two departments of which are still known, the one as Vesterbotten or West Bothnia, and the other as Norrbotten or North Bothnia. The name is probably derived from the Scandinavian *botn*, a lake.

BOTHNIA, GULF OF, the northern part of the Baltic, so called from the above province. See BALTIC SEA.

BOTHWELL, a village of Scotland, in Lanarkshire, situated near the River Clyde, about 8½ miles S.E. of Glasgow, and a favourite resort of the inhabitants of that city. It contains a Gothic church of some antiquity; and about a mile from the village are the ruins of Bothwell Castle and the modern mansion of Lord Douglas. In the neighbourhood is the scene of the famous battle of Bothwell Bridge, which was fought between the Covenanters and the forces of the duke of Monmouth, June 22, 1679. Bothwell is one of the most ancient baronies in Scotland, and gives a title to a series of families distinguished in the history of Scotland. Joanna Baillie was born in the village manse. The population of the parish in 1871 was 9193.

BOTHWELL, JAMES HEPBURN, EARL OF, in the peerage of Scotland, only son of Patrick, third earl of Bothwell, was born about 1526. Nothing is known of his life up to the date of his father's death, 1556, when he was served heir to his vast estates. For the next few years notices of his doings are few and obscure; he undoubtedly held posts of high dignity, such as the wardenship of the Scottish Borders, and the office of Lord Admiral; and it is certain that he was a vigorous opponent of the "lords of the congregation." In the end of 1560 he appears to have been one of the lords who went over to France to meet their new queen (Mary). In 1562 occurred the singular and obscure episode of the conspiracy between Bothwell and Arran to carry off the queen. Arran was well known to be deeply enamoured of Mary, and Bothwell apparently intended to use this passion as a means of furthering his own designs against Murray. The plot, or the germ of it was discovered; Arran was found to be all but insane, and an indictment was laid against Bothwell, who fled to France and remained there till 1565, when he returned to Scotland. The charge, however, was not forgotten; it was renewed by the earl of Murray, and the day of trial was fixed. But Murray's forces were too umerous to make it safe for Bothwell to make his aparance, and he again fled. He reappeared at court in a rt time after the marriage of the queen with Darnley, and began to rise rapidly into favour. He escaped from the palace after the murder of Rizzio, and with great promptitude drew together some forces for the queen's defence. From this time onwards he was in the highest favour with the queen, and all powerful at court. In 1566 he was dangerously wounded when on a judicial tour in Liddesdale. Here the queen paid him a visit, riding all the way from Jedburgh, where she was holding a justice eyre. The fatigues of this ride of forty miles brought on a severe illness, during which her life was despaired of. After her recovery the project of a divorce from Darnley was mooted, but was declined by her, and Bothwell seems then to have resolved on the removal of her husband by any means. On the evening of the 9th of February the famous crime was committed of Darnley's murder. Public opinion, expressing itself in placards and outcries, fastened the guilt upon Bothwell and his associates, but he was too powerful to be dealt with by the law. On the 24th April he played his last move, carrying off Mary to Dunbar Castle, which had been granted him by the Queen. A divorce from his former wife was easily procured, the dispensation in their favour not being produced at the trial, and on the 15th May the royal marriage was completed. Mary had a few days previously pardoned Bothwell for his abduction of her, and had raised him to the rank of duke of Orkney. The fancied security in which they passed the few days after their marriage was soon and rudely dispelled. The great lords collected their forces and seized Edinburgh, Bothwell and the queen escaping with the greatest difficulty to Dunbar. At Carberry Hill the opposing parties met; Mary surrendered to the lords, and Bothwell fled to Dunbar and thence to Orkney. Being closely pursued he took ship, was captured by a Danish cruiser, and confined for a time at Copenhagen. He was removed to Malmö and afterwards to Draxholm Castle, where he died in 1575. He is said to have made a death-bed confession exonerating the queen, but the authenticity of the report is more than doubtful. There is hardly a redeeming point in Bothwell's character; he was utterly selfish and brutal, and did not even treat with courtesy or kindness the woman who had risked so much for his sake. (See Tytler and Burton's histories of Scotland.)

BOTTA, CARLO GIUSEPPE GUGLIELMO, Italian historian, was born in 1766 at San Giorgio, in Piedmont. He studied medicine at the university of Turin, and obtained his doctor's degree when about twenty years of age. Having rendered himself obnoxious to the Government during the political commotions that followed the French Revolution, he was imprisoned for nearly two years; and on his release in 1794 he withdrew to France, only to return to his native country as a physician in the French army, whose progress he followed as far as Venice. Here he joined the expedition to Corfu, from which he did not get back to Italy till 1798. From that year, when he was appointed by Joubert a member of the provisional government at Piedmont, till the fall of the Napoleonic system in 1814, he continued to have considerable political influence; and though towards the close of that period he acted with an independence that proved offensive to Napoleon himself, and on the restoration of the Bourbons adapted his conduct to the circumstances of the time, he was still in sufficient favour with the Bonapartist party to receive from them, during their brief resumption of authority in 1815, the appointment (soon afterwards resigned) of rector of the university at Rouen. Amid all the vicissitudes of his early manhood Botta had never allowed his pen to be long idle, and in the political quiet that followed 1816 he naturally devoted himself more exclusively to literature. By 1824 he had completed a history of Italy from 1789 to 1814 (4 vols.), on which his fame principally rests, for

though the continuation of Guicciardini, which he was afterwards encouraged to undertake, is a careful and laborious work, he had not the erudition necessary for the satisfactory restoration of the past. Though living in Paris he was in both these works the ardent exponent of that recoil against everything French which took place throughout Europe. A careful exclusion of all Gallicisms is one of the marked features of his style, which is not unfrequently impassioned and eloquent, though at the same time cumbrous and founded upon antiquated models. Botta died at Paris in August 1837, in comparative poverty, but in the enjoyment of an extensive and well-earned reputation. His son, Paul Émile Botta (1805–1870), was a distinguished traveller and Assyrian archæologist. His excavations at Khorsabad (1843) were among the first efforts in the line of investigation afterwards pursued by Mr Layard.

The works of Carlo Botta are—*Description de l'île de Corfou*, 1799; an Italian translation of Born's *Joannis Physiophili specimen monachologiæ*, 1801; *Souvenirs d'un voyage en Dalmatie*, 1802; *Mémoire sur la nature des tons et des sons*, 1803; *Storia della guerra dell' Independenza d'America*, 1810; *Camillo*, a poem, 1816; *Storia d'Italia dal 1789 al 1814*, 1824; *Storia d'Italia in continuazione al Guicciardini*, 1832, &c., &c.

BOTTICELLI, SANDRO (for ALESSANDRO), one of the most original and fascinating painters of the school of Florence. Like many Italian artists, he is called not after his father but after the master under whom he learned his first lessons in art. He was the youngest son of a citizen named Mariano Filipepi, and was born at Florence in the year 1447. It is related how as a child, though quick at whatever he chose to do, he was restless and wayward, and would not take kindly to "any sort of schooling in reading, writing, or arithmetic;" so that his father put him, in despair, to learn the goldsmith's trade with a gossip of his own named Botticello. Thus his first training, like that of Ghirlandaio and many of the best artists of the time, was in jewellery and metal working. He showed talent and fancy, and was presently transferred from the school of Botticello the goldsmith to that of Lippo Lippi the Carmelite brother, then in the height of his practice and reputation as a painter. Under that master Sandro acquired a perfect proficiency, and on his death in 1468 appears to have begun independent practice. The special characteristic of Lippo Lippi's style had been its union of a buoyant human spirit of life and enjoyment with the utmost simplicity and tenderness of religious feeling. In Botticelli there was more than all the fire of his master, and more than all his delight in beauty, together with a sentiment which was altogether personal to himself. All his creations are coloured with an expression of eager and wistful melancholy, of which it is hard to penetrate the sense and impossible to escape the spell. Whether he paints a Madonna with her child surrounded by angels, or a Venus among her Graces and Cupids, the countenances which he shows us are of a kindred type, and have upon them the pale cast of the same nameless passion. He was an artist of immense invention and industry, and in the early part of his career painted in oil and tempera a vast number of pictures both in the classical and the Christian vein. No other work expresses the spirit of the time in a more interesting way, or with so much imaginative refinement and technical charm. His dejected types have an infinite beauty of their own, and though his figures are not designed with perfect science, and have some tendency to attenuation, and to coarseness of the hands and feet, they are nevertheless drawn with a determination and finish in the contours, and modelled with a fulness and delicacy of relief, which belong only to the most accomplished art.

Of all the Florentine school, Botticelli is the richest and most fanciful colourist,—often using gold to enrich the lights on hair, tissues, and foliage, with a very exquisite effect. That may be the consequence of his early employment upon goldsmith's work, as is, more certainly, his minute solicitude in all the accessory details and ornaments of his compositions. The patterned and embroidered dresses, the scarves and head-gear of his figures, are often treated with an incomparable invention and delicacy. No artist has ever painted flowers with a more inspired affection, and especially roses, with which he was wont to fill the backgrounds of his pictures. He preferred, it would seem, the circular form for his compositions; and a large number of devotional pieces in this form, by his own hand and that of his scholars, are scattered through the museums and private collections of Europe, and are among the most poetical examples of religious art that Italy has left us. He went even beyond his master Lippo Lippi, and the sculptors Luca della Robbia, Donatello, and Desiderio da Settignano, in the touching and engaging character of the children who minister, in the form of angels, to his sacred personages. He designed choirs of such or of grown-up angels dancing between earth and heaven, or circles of them ranged in the order of the celestial hierarchies, with a variety of grouping and a graceful fire of movement that was a new thing in his art. One of the best examples of this kind of work is a round numbered 33 in the gallery of the Uffizj at Florence. Another very famous example of his devotional art is a picture of the Coronation of the Virgin executed for Matteo Palmieri, a Florentine man of letters and speculative philosopher, with whom the painter was intimate, and who gave suggestions for the design of the picture. It represents the Virgin and Christ surrounded by the celestial hierarchies according to the scheme (with some slight divergencies) of Dionysius the Areopagite,—on the ground beneath, the donor and his wife kneeling at either side of the Virgin's tomb, the Val d'Arno and the city of Florence in the distance. This picture is now the property of the duke of Hamilton. But the grandest of all his altar-pieces is that numbered 47 in the Florence Academy, with a group of life-sized saints on the ground and a dance of angels above. In the Uffizj is an Adoration of the Magi, in which Botticelli has introduced the portraits of Cosimo, Giuliano, and Giovanni de' Medici. By that house he, like all the artists of his time, was much befriended; and for Lorenzo's villa at Castello he painted the most beautiful of his pictures of classical mythology, the Birth of Venus now at the Uffizj, and the Venus with the Graces now at the Florence Academy. The National Gallery possesses two smaller but admirable works of the master in the same vein. An allegorical figure of Fortitude, designed for a series of which the rest were painted by the brothers Pollaiuoli, and now in the Uffizj; a picture composed from Lucian's account of the Calumny of Apelles in the same gallery; a series illustrating Boccaccio's story of Nastagio degli Onesti, which has passed into private hands in England—these instances will suffice to show the variety of themes upon which Botticelli exercised his genius. A St Augustine, painted by him in rivalry with Ghirlandaio in the church of the Ognissanti, and still existing, is said to have won great praise from his contemporaries for its exhibition, in the head of the saint, of "that profound cogitation and most acute subtlety which we are wont to find in persons who are of thoughtful habit and continually abstracted in the investigation of things the most deep and difficult."

wards that he was summoned to Rome by Sixtus IV., to decorate the walls of his new chapel in the Vatican. Among the great scenes in fresco painted on those walls by Domenico Ghirlandaio, Cosimo Rosselli, Signorelli, and Perugino, three subjects from the hand of Botticelli hold their place with the noblest. They represent the Life of Moses, the Destruction of Korah, Dathan, and Abiram, and the Temptation of Christ. In 1482, probably after his return from Rome, he received a commission to paint in the Sala dell' Udienza at Florence, together with Domenico Ghirlandaio. Many of the works already mentioned probably fall within the next ten years of Botticelli's manhood. The Boccaccio series belongs to 1487. In 1491 he was engaged, together with the brothers Ghirlandaio, upon some mosaic decorations in the cathedral of Florence which have unhappily perished. Soon after this time there came into his life a new influence which greatly changed it. It is well known how the genius of the Dominican Savonarola swept like a storm over the affairs of Italy, and what a revolution, after the passage of the French king through Florence, he brought about in the temper and policy of the republic,—driving out the merchant family who had been its untitled masters for half a century, establishing in place of their rule a new theocracy of which he was himself the oracle and minister, turning the hearts of old and young away from the world and from their lusts. Many of the first artists of the city became his most ardent followers, and among them Botticelli. What the actual effect of his conversion was upon him we have scanty means of judging, but it needs must have put an end to his painting of those old mythologies, over which in earlier days his imagination had been used to throw so singular a charm. Vasari, a devoted servant of the later Medici, and therefore a traducer of the greatest enemy that house had ever had, speaks of Savonarola's influence upon Botticelli as altogether disastrous, saying that he was "obstinate upon that side," "a partisan of the sect of Savonarola in such a fashion that, abandoning painting and having no income to live upon, he fell into the utmost disorder;" and again how, "playing the Piagnone (the name given to the followers of Savonarola), he fell out of the way of painting, and thereby at last found himself old and poor in such a sort that if Lorenzo Medici, as long as he lived, had not supported him, and afterwards his friends and many worthy men who felt an affection for his virtues, he would, we may say, have died of hunger." We have few materials by which we can test the accuracy of this account. We know that in 1496 the young Michelangelo sent through his hands a letter addressed to this Lorenzo de' Medici (Lorenzo the younger, that is,—the son of Giuliano); that in 1498 he was living with a brother in the quarter called Sta Lucia of Ognissanti; that in 1503 he was consulted along with other artists as to the best place for Michelangelo's colossal statue of David. But of more importance and significance than all this is a beautiful picture of a Nativity with mystical by-scenes, in the possession of Mr Fuller Maitland, which bears an inscription in base Greek by the master himself. The inscription seems to construe thus:—"This picture I, Alessandro, painted at the end of the year 1500, in the troubles of Italy, in the half-time after the time, during the fulfilment of the eleventh of John, in the second woe of the Apocalypse, in the loosing of the devil for three and a half years. Afterwards he shall be chained according to the twelfth of John, and we shall see him trodden down as this picture." Hence it appears to be established that Botticelli, a year and a half after the downfall and execution of Savonarola, had his mind full of his instructions and prophecies; that he regarded the death of the Dominican reformer and his companions as the fulfilment of the Apocalyptic prophecies about the slaying of the witnesses; that he thought of the tribulations among which he lived as the "second woe" of Rev. xi., and as coincident with the "time, times, and half a time" of that and other prophetic writings; and finally—such is the originality and excellence of the work—that his imagination had at this time lost none of its fire nor his hand of its cunning. We are quite without the means of deciding whether any proportion of the large existing mass of his undated works belong to the years following this; or whether we are really to think of him as failing in his wonted industry in his latter days, from regret and disappointment at his master's fate and at public affairs, from pre-occupation over mystical theology (which had always had an attraction for him, and, in the case of the picture painted early in his life for Matteo Palmieri, had brought upon him a charge of heresy), or, lastly, from another cause which Vasari alleges, but which we have designedly passed by till this place.

In the history of engraving there are no productions more precious, more interesting, or more problematical than a number of plates executed in a primitive style, with severe outlines and straight lines of shading, by artists of the Florentine school towards the close of the 15th century. The engravings in this manner include some two hundred and fifty pieces, covering the whole range of subjects that interested the mind of Italy at this most active and fanciful moment of the early Renaissance. The best known of these engravings are as follows:—three designs to the earliest book published in Florence with engraved illustrations, called *Il Monte Sancto di Dio* (1471); a set of nineteen designs to an edition of the *Divina Commedia* of Dante (1481); a set of twenty-four Prophets; a set of twelve Sibyls; several subjects of Saints; several of mythology, such as the Death of Paris, Theseus and Ariadne, the Judgment of Paris, Loves in a Vineyard, and the like; a famous series (long falsely ascribed to Mantegna, whose manner in engraving is easily distinguishable from this) of the Ranks and Professions of Men, the Virtues, the Arts and Sciences, the Muses, and the Planets (fifty in all); a series of fifteen setting forth the lives of Mary and of Christ; a subject of the deluge; another of the preaching of the Franciscan Fra Marco, and many more. Between the various examples of this large class there are considerable differences, but they are all unlike the work of any other school, and all manifestly Florentine of the 15th century. Conjectures the most confident and at the same time the most conflicting have been put forward as to their authorship. All such conjectures alike have been based on a few passages in Vasari's lives of Botticelli and of Marc Antonio. According to Vasari, the first Florentine who took impressions on paper from engravings was Maso Finiguerra, and he, says our author, was "followed by Baccio Baldini, who not having much power of designing, all that he did was with the invention and design of Sandro Botticelli." And again, Vasari says of Botticelli that, "from being a sophistical (*i.e.*, thoughtful or ingenious) person, he commented a part of Dante, and made figures for the *Inferno*, and put them into print; upon which pursuit he spent a deal of time; so that not working" (*i.e.*, at painting) "it was a cause of infinite disorders in his life. He put in print many more things of his own from designs which he had made, but in a bad manner." On the strength of those passages this whole class of early Florentine engravings has generally been put down by connoisseurs, as, for instance, Young Ottley, Bartsch, and Passavant, as the work of Sandro Botticelli and Baccio Baldini, jointly or apart,—each critic attributing separate subjects to the one or the other of the artists according to his private canon of internal evidence. But a scrupulous examination shows this internal evidence to be both very meagre and very contradictory. Nor can much be built upon the external

testimony of Vasari. The phrase "put into print" is ambiguous, and by it Vasari may mean us to understand either that Botticelli engraved the designs himself or else that he merely furnished them to be engraved by another hand. To him the chief part in the invention, to Baldini the chief part in the execution, is usually and with a fair measure of probability assigned. Vasari's information on the whole subject was evidently loose; a Triumph of Faith of Savonarola, which he extols as Botticelli's best engraving, does not at present exist at all. None of the designs bear the evidence of Botticelli's manner in a sufficiently definite form to be undeniable. On the other hand, many of them, by their poetry, their refinement, their singularity, are quite worthy of his hand, nor do they resemble any other contemporary style more than his. If he designed and executed, or in part executed, them, they are no slight addition to his fame, and a noble vindication of his industry during that old age of idleness, decay, and "disorder," which followed, if we are to believe Vasari, upon the splendid and inspired activity of his youth and manhood. But the question is one which criticism, it is to be feared, will never have the means of fully settling. (Vasari, ed. Lemonnier, vol. v. pp. 110–127; Crowe and Cavalcaselle, *Hist. of Painting in Italy*, vol. ii. pp. 414–430; W. H. Pater, *Studies in the History of the Renaissance*; and see also *Ariadne Florentin*, No. vi., by John Ruskin; art. "Baccio Baldini," by E. Kolhoff in 2d ed. of Nagler's *Künstler-Lexikon*; and the *Academy* for February 1871.)

BÖTTIGER, KARL AUGUST, a distinguished German archæologist, was born at Reichenbach in 1760. He was educated at the famous school of Pforta, and at the University of Leipsic. In 1784, after having passed a few years as private tutor in Dresden, he was made rector of the school at Guben, where he remained for six years. He was then transferred to a similar post at Bautzen, and in 1791, through the influence of Herder, obtained the appointment of rector of the gymnasium at Weimar. In that town he entered into a circle of literary men of the highest powers, including Wieland, Schiller, and Goethe, and distinguished himself by the great versatility of his talents. He published in 1803 a lively and learned work, *Sabina, oder Morgenscenen einer reichen Römerin*, giving a description of a wealthy Roman lady's toilette, and a work on ancient art, *Griechische Vasengemälde*. At the same time he assisted in editing the *Journal des Luxus und der Mode*, the *Deutsche Mercur*, and the *London and Paris*. In 1804 he was called to Dresden as superintendent of the studies of the court pages, and received the rank of privy councillor. In 1814 he was made director of studies at the court academy, and inspector of the Museum of Antiquities. He died at Dresden in 1835.

Of his numerous works, most of which are devoted to ancient art, the following seem most worthy of notice:—*Ideen zur Archäologie der Malerei*, 1811; *Kunstmythologie*, 1811; *Vorlesungen und Aufsätze zur Alterthumskunde*, 1817; *Amalthea*, 3 vols., 1821-25; *Ideen zur Kunstmythologie*, 2 vols., 1826–36. The *Opuscula et Carmina Latina* were published separately in 1837, with a collection of his smaller pieces, *Kleine Schriften*, 3 vols., 1837–8. A sketch of his biography has been written by his son, Karl Wilhelm Böttiger (1790-1862), for some time professor of history at Erlangen, who is well known as the author of several valuable histories (*History of Germany*, *History of Saxony*, *History of Bavaria*, *Universal History in biographies*.)

BOTTLE. The first bottles were probably made of the skins of animals. In the *Iliad* (iii. 247) the attendants are represented as bearing wine for use in a bottle made of goat's skin, ἀσκῷ ἐν αἰγείῳ. The ancient Egyptians used skins for this purpose, and from the language employed by Herodotus (ii. 121), it appears that a bottle was formed by sewing up the skin and leaving the projection of the leg and foot to serve as a vent, which was hence termed ποδεών. The aperture was closed with a plug or a string. Skin bottles of various forms occur on Egyptian monuments. The Greeks and Romans also were accustomed to use bottles made of skins; and in the southern parts of Europe they are still used for the transport of wine. The

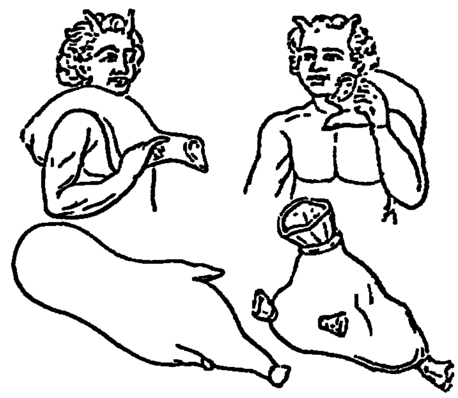

FIG. 1.—Roman Skin Bottles.

accompanying illustration is from specimens at Pompeii and Herculaneum. The first explicit reference to bottles of skin in Scripture occurs in Joshua (ix. 4), where it is said that the Gibeonites took "old sacks upon their asses, and wine-bottles *old and rent and bound up*." Skins are still most extensively used throughout Western Asia for the conveyance and storage of water. It is an error to represent the bottles of these ancient Hebrews as being made exclusively of skins. In Jer. xix. 1, the prophet speaks of "a potter's earthen vessel." The Egyptians possessed vases, bottles, &c., of hard stone, alabaster, glass, ivory, bone, porcelain, bronze, silver, and gold, and also, for the use of the people generally, of glazed pottery or common earthenware. As early as Thothmes III., assumed to be the Pharaoh of the Exodus (1490, B.C.), vases existed of a shape so elegant, and of workmanship so superior, as to show that the art was not, even then, in its infancy. In the annexed cut various specimens of these are represented.

FIG. 2.—Egyptian Bottles and Vases.—1, 2. Gold. 3. Cut glass. 4. Earthenware. 5, 7. Porcelain. 6. Hard Stone. 8. Gold, with plates and bands. 9. Stone. 10. Alabaster, with lid.

The British Museum contains a fine collection of these articles. The process of making glass bottles is described under the heading GLASS.

BOTTOMRY, a maritime contract by which a ship (or bottom) is hypothecated in security for money borrowed for expenses incurred in the course of her voyage, under the condition that if she arrive at her destination the ship shall be liable for repayment of the loan, together with such premium thereon as may have been agreed for; but that if the ship be lost, the lender shall have no claim against the borrower either for the sum advanced or for the

premium. The freight may be pledged as well as the ship, and, if necessary, the cargo also. In some cases the personal obligation of the ship-master is also included. When money is borrowed on the security of the cargo alone, it is said to be taken up at *respondentia*; but it is now only in rare and exceptional cases that it could be competent to the ship-master to pledge the cargo, except under a general bottomry obligation, along with the ship and freight. In consideration of the risks assumed by the lender, the bottomry premium (sometimes termed *maritime interest*) is usually high, varying of course with the nature of the risk and the difficulty of procuring funds.

A bottomry contract may be written out in any form which sufficiently shows the conditions agreed on between the parties; but it is usually drawn up in the form of a *bond*. The document must show, either by express terms or from its general tenor, that the risk of loss is assumed by the lender,—this being the consideration for which the high premium is conceded. The lender may transfer the bond by endorsation, in the same manner as a bill of exchange or bill of lading, and the right to recover its value becomes vested in the indorsees.

According to the law of this country, a bottomry contract remains in force so long as the ship exists *in the form of a ship*, whatever amount of damage she may have sustained. Consequently, the "constructive total loss" which is recognized in marine insurance, when the ship is damaged to such an extent that she is not worth repairing, is not recognized in reference to bottomry, and will not absolve the borrower from his obligation. But if the ship go to pieces, the borrower is freed from all liability under the bottomry contract; and the lender is not entitled to receive any share of the proceeds of such of the ship's stores or materials as may have been saved from the wreck. Money advanced on bottomry is not liable in England for general average losses.

If the ship should *deviate* from the voyage for which the funds were advanced, her subsequent loss will not discharge the obligation of the borrower under the bottomry contract. If she should not proceed at all on her intended voyage, the lender is not entitled to recover the bottomry premium in addition to his advance, but only the ordinary rate of interest for the temporary loan. As the bottomry premium is presumed, in every case, to cover the risks incurred by the lender, he is not entitled to charge the borrower with the premium which he may pay for *insurance* of the sum advanced, in addition to that stipulated in the bond.

The contract of bottomry seems to have arisen from the *custom* of permitting the master of a ship, when in a *foreign* country, to pledge the ship in order to raise money for repairs, or other extraordinary expenditures rendered necessary in the course of the voyage. Circumstances often arise, in which, without the exercise of this power on the part of the master, it would be impossible to provide means for accomplishing the voyage; and it is better that the master should have authority to burden the ship, and, if necessary, the freight and cargo also, in security for the money which has become requisite, than that the adventure should be defeated by inability to proceed. But the right of the master to pledge the ship or goods must always be created by necessity; if exercised without necessity the contract will be void. Accordingly, the master of a British ship has no power to grant a bottomry bond at a British port, or at any foreign port where he might raise funds on the personal credit of the shipowners. Neither has he any power to pledge the ship or goods for private debts of his own, but only for such supplies as are indispensable for the purposes of the voyage. And in all cases he ought, if possible, to communicate with the owners of the ship, and with the proprietor of the cargo before pledging their property. Facility of communication, by telegraph and otherwise, has of late years given additional stringency to this rule.

The bottomry lender must use reasonable diligence to ascertain that a real necessity exists for the loan; but he is not bound to see to the application of the money advanced. If the lender has originally advanced the funds on the personal credit of the owner he is not entitled to require a bottomry obligation. A bond procured from the shipmaster by improper compulsion would be void.

The power of the master to pledge the cargo depends upon there being some reasonable prospect of benefit to it by his so doing. He has no such power except in virtue of circumstances which may oblige him to assume the character of *agent for the cargo*, in the absence of any other party authorized to act on its behalf. Under ordinary circumstances he is not at liberty to pledge the cargo for repairs to the ship. If indeed the goods be of a perishable nature, and if it be impossible to get the ship repaired in sufficient time to obviate serious loss on them by delay, without including them under the bottomry contract, he has power to do so, because it may fairly be assumed, in the case supposed, that the cargo will be benefited by this procedure. The general principle is, that the master must act for the cargo, with a reasonable view to the interests of its proprietors, under the whole circumstances of the case. When he does this his proceedings will be sustained; but should he manifestly prejudice the interests of the cargo by including it under bottomry for the mere purpose of relieving the ship, or of earning the freight, the owners of the cargo will not be bound by the bottomry contract. Any bottomry or respondentia bond may be good in part or bad in part, according as the master may have acted *within* or *beyond* the scope of his legitimate authority in granting it. If two or more bottomry bonds have been granted at different stages of the voyage, and the value of the property be insufficient to discharge them all, the last dated bond has the priority of payment, as having furnished the means of preserving the ship, and thereby preventing the total loss of the security for the previous bonds.

When the sum due under a bottomry bond over ship, freight, and cargo is not paid at the stipulated time, proceedings may be taken by the bondholder for recovery of the freight and for the sale of the ship; and should the proceeds of these be insufficient to discharge the claim, a judicial sale of the cargo may be resorted to. As a general rule the value of the ship and freight must be exhausted before recourse can be taken against the cargo. A bottomry bond gives no remedy to the lenders against the owners of the ship or cargo personally. The whole liability under it may be met by the surrender of the property pledged, whether the value so surrendered covers the amount of the bond or not. But the owners of the ship, though not liable to the bondholder for more than the value of the ship and freight, may be further liable to the proprietors of the cargo for any sum in excess of the cargo's proper share of the expenses, taken by the bondholder out of the proceeds of the cargo to satisfy the bond after the ship and freight have been exhausted.

The bottomry premium must be ultimately paid by the parties for whose benefit the advances were obtained, as ascertained on the final adjustment of the average expenditures at the port of destination.

BOTZEN, BOZEN, or BOLZANO (the ancient *Pons Drusi*), a town of Austria, the capital of the circle of Brixen in Tyrol, is situated at a height of 1120 feet near the confluence of the Talfer and the Eisack, 32 miles N.N.E. of Trent. The town is well built in the Italian style, and has a fine old Gothic church of the 14th and 15th centuries, a castle, several churches and convents, and a gymnasium. Situated at the intersection of roads from Italy, Germany, and Switzerland, it has an extensive transit trade, and its four large annual fairs date from 1024. It has also manufactures of linen, cotton, silk, hosiery, leather, and wax. It is protected from sudden inundations by a strong dike of masonry nearly two miles in length, and in some parts 24 feet thick. Botzen is mentioned as early as 378. In the 9th century it was the seat of a Bavarian countship, but in 1027 it was presented to the prince-bishop of Trent by the Emperor Conrad II. For centuries after that date it continued to be an object of strife between the Germans and Italians, until at last, in 1531, the authority of the count of Tyrol was acknowledged on all hands. Since then the city has followed the fortunes of Tyrol.

BOUCHES-DU-RHONE, a department of France, situated along the south coast, and, as the name imports, at the mouth of the Rhone. It is bounded on the N. by Vaucluse, from which it is separated by the Durance; on the E. by Var, and W. by Gard; and its area is estimated at 1963 English square miles. The western portion consists of a low and marshy plain, known as the Camargue, which is remarkable for its unhealthiness; to the east of this is situated the remarkable stretch of country called the Crau, which is strewn with pebbles like the sea beach; and further east and north there are various ranges of mountains of moderate elevation belonging to the Alpine system. A few small tributaries of the Rhone and the Durance and a number of streams, such as the Arc, the Touloubre, and the Huveaune, which find their way directly to the sea, are the only rivers that properly belong to the department. The proportion of arable land is exceedingly small, though the quantity has been considerably increased by artificial irrigation. Wheat is cultivated with success in some parts of the Camargue, and, if labour were more easily obtainable, rice might also be grown. Horses and cattle are reared in a half wild condition, and large flocks of sheep are pastured during the winter on the herbage that springs up among the pebbles of the Crau. The numbers of domestic animals in the department were in 1872 as follows:—horses 20,665, cattle 2686, sheep 262,566, and goats 17,560. The only mineral furnished to any extent by the department is coal, in the mining of which between 1000 and 2000 workmen are engaged, but there are also quarries of limestone, sandstone, slate, gypsum, marl, and marble. The salt marshes, which cover an area of 2290 acres, employ more workmen than the coal-mines, and the amount of salt obtained exceeds in quantity the produce of any other department in France. There are extensive manufactures of soaps, perfumes and oils, soda, sulphur, sugar, woollen hosiery, and leather, and a variety of other articles. The foreign commerce of the department, which is principally carried on in the Mediterranean basin, is for the most part concentrated in the capital, Marseilles; the minor ports are Martigues, Cassis, and Ciotat. The department is divided into the three arrondissements of Marseilles, Aix, and Arles; the more important towns in which (in addition to their capitals) are respectively Aubagne, Ciotat, and Roquevaire; Martigues, Salon, and Istres; and Tarascon, Saint Remy, and Châteaurenard. Among the numerous men of mark belonging to Bouches-du-Rhone are D'Urfé, Massillon, Vanloo, Tournefort, Barthélemy, Vauvenargues, Thiers, Mignet, Achard, and Reinaud. The population, which in 1872 amounted to 554,911, contains a large proportion of foreigners, mostly of Italian nationality. The total alien element in 1872 was represented by 42,855, the Italian by 33,500.

BOUFARIK (the "Hanging Well"), a town of Algeria, in the province of Algiers and arrondissement of Blidah, about 21 miles from the city of Algiers near the railway thence to Blidah. It is a thoroughly French town, and only dates from 1835, when General Drouet d'Erlon established an entrenched camp on what was then a mere hillock in the midst of an almost uninhabitable marsh. Shortly after Marshal Clausel determined to build a regular city, which was at first called Medina Clausel in his honour. The draining of the site and neighbourhood was a costly undertaking, and was only accomplished by the sacrifice of many lives. The town is now one of the most flourishing in the country, is surrounded by vast orchards and farms, and affords a market to the pastoral Arabs of the Metidja. There are flax-dressing and spinning mills, and the manufacture of essences and perfumes is carried on to a considerable extent. The population, which is composed of very various elements, amounted in 1872 to 2588.

BOUFLERS, LOUIS FRANÇOIS, DUC DE, commonly called the Chevalier Bouflers, a peer and marshal of France, and a general of distinguished reputation, was born January 10, 1644. Having early entered the army, he was raised in 1669 to the rank of colonel of dragoons. In the conquest of Lorraine he served under Marshal de Créquy. In Holland he served under Turenne, frequently distinguishing himself by his skill and bravery; and when that celebrated leader was killed by a cannon-shot in 1675, he commanded the rear-guard during the retreat of the French army. After performing various military services in Germany, in Flanders, and on the frontiers of Spain, he was created, in 1690, general of the army of the Moselle, and contributed materially to the victory of Fleurus. In the following year he acted as lieutenant-general, under the king in person; and during the investment of Mons, he was wounded in an attack on the town. He conducted the bombardment of Liége, which was defended by an enemy superior in numbers, and afterwards forced the allied generals to abandon Luxembourg. He was entrusted with the command against King William at the siege of Namur, and took part in the victory of Steinkirk. For these important services he was raised in 1693 to the rank of marshal of France, and in 1695 was made a duke. In 1694 he was appointed governor of French Flanders and of the town of Lille. By a skilful manœuvre he threw himself into Namur in 1695, and obstinately held out for four months during which the besiegers lost 20,000 men. In the conferences which terminated in the peace of Ryswick he had a principal share. During the following war, when Lille was again threatened with a siege by the duke of Marlborough and Prince Eugene, Bouflers was appointed to the command, and made an obstinate resistance of four months. He was rewarded and honoured by the king for his defence of Lille, as if he had been victorious. It was indeed a species of triumph; his enemy, appreciating his merits, allowed him to dictate his own terms of capitulation. When the affairs of France were threatened with the most urgent danger, Bouflers offered to serve under his junior, Villars, and was with him at the battle of Malplaquet. Here he again displayed his military skill, by conducting th[illegible]

di

a

In 1755 he was sent to London as secretary to the French embassy, and was chosen a member of the Royal Society. In 1756 he went to Canada as captain of dragoons and aide-de-camp to the marquis of Montcalm; and having distinguished himself in the war against England, was rewarded with the rank of colonel and the cross of St Louis. He afterwards served in the Seven Years' War from 1761 to 1763. After the peace, when the French Government conceived the project of colonizing the Falkland Islands, Bougainville undertook the task at his own expense. But the settlement having excited the jealousy of the Spaniards, the French Government gave it up to them, on condition of their indemnifying Bougainville. He was then appointed to the command of the frigate "La Boudeuse" and the transport "L'Étoile," on a voyage of discovery round the world. He set sail from Nantes in November 1766, taking with him Commerçon as naturalist, and Verron as astronomer. Having executed his commission of delivering up the Falkland Islands to the Spanish, Bougainville proceeded on his expedition, and touched at Buenos Ayres. Passing through the Straits of Magellan, he anchored at Otaheite, where the English navigator Wallis had touched eight months before. The expedition having crossed the Pacific Ocean, and the men now suffering from scurvy, the ships came to anchor off the Island of Boron, one of the Moluccas, where the governor of the Dutch settlement supplied their wants. It was the beginning of September, and the expedition took advantage of the easterly monsoon, which carried them to Batavia. Thence they proceeded to the Isle of France, where they left Commerçon and Verron. In 1769 the expedition arrived at St Malo, after a voyage of two years and four months, with the loss of only seven out of upwards of 200 men. Bougainville's account of the voyage (Paris, 1771, 4to) is written with simplicity and with some humour. The art of making astronomical observations at sea was then much less perfect than now, and, consequently, Bougainville's charts are found to be erroneous, particularly as to the longitudes. After an interval of several years, he again accepted a naval command and saw much active service between 1779 and 1782. In the memorable engagement of April 12, 1782, in which Rodney defeated the Count de Grasse, near Martinique, Bougainville, who commanded the "Auguste," succeeded in rallying eight ships of his own division, and bringing them safely into St Eustace. After the peace he returned to Paris, and solicited and obtained the place of associate of the Academy. He projected a voyage of discovery towards the north pole, but this did not meet with support from the French Government. Bougainville obtained the rank of vice-admiral in 1791; and in 1792, having escaped almost miraculously from the massacres of Paris, he retired to his estate in Normandy. He was chosen a member of the Institute at its formation; and then returning to Paris succeeded Borda as member of the Board of Longitude. In his old age Napoleon I. made him a senator, count of the empire, and member of the Legion of Honour. He died at Paris, August, 31, 1814. He was married and had three sons, who served in the French army. His *éloge*, composed by Delambre, appears in the *Memoirs of the Institute*.

BOUGIE, or BOUGIAH, a fortified seaport town of Algeria, in the province of Constantine and arrondissement of Sétif, betweeen Cape Carbon and the Wady-Sahell. Among its more important buildings are the French church, the hospital, the barracks, the magazines, and the Abd-el-Kader fort, now used as a prison. Trade is carried on in wax, grain, oranges, oil, and wine. A basin was constructed about 1870 in the anchorage below the town. The population in 1872 was 2820, of whom 1134 were natives. Bougie, Bugia, or Bugiah is a town of great antiquity. If it is correctly identified with the *Salda* of the Romans it probably owes its origin to the Carthaginians. Genseric, the king of the Vandals, surrounded it with walls and chose it as his capital for some time; and in the 10th century it became, under the Beni-Hammad, the greatest commercial city of the North African coast. The Italian merchants of the 12th and 13th centuries had numerous buildings of their own in the city, such as warehouses, baths, and churches. It became a haunt of pirates in the 15th century, and in the beginning of the 16th it was captured by the Spaniards, from whom it was taken by the Turks in 1555. It was a place of little importance when it fell into French possession about 1833.

BOUGUER, PIERRE, an eminent French mathematician, was born in 1698. His father, one of the best hydrographers of his time, was regius professor of hydrography at Croisic in Lower Britanny, and author of an excellent treatise on navigation. Young Bouguer was bred to mathematics from his infancy, and at an early age was appointed to succeed his father as professor of hydrography. In 1727 he gained the prize given by the Academy of Sciences for his paper "On the best manner of forming and distributing the Masts of Ships;" and two other prizes, one for his dissertation "On the best method of observing the Altitude of Stars at Sea," the other for his paper "On the best method of observing the Variation of the Compass at Sea." These are published in the *Prix de l'Académie des Sciences*. In 1729 he published *Essai d'optique sur la gradation de la lumière*, the object of which is to define the quantity of light lost by passing through a given extent of the atmosphere. He found the light of the sun to be 300 times more intense than that of the moon. He was soon after made professor of hydrography at Havre, and succeeded Maupertuis as associate geometer of the Academy of Sciences. He was afterwards promoted in the Academy to the place of pensioned astronomer, and went to reside in Paris. In 1735 Bouguer sailed with Godin and De la Condamine for Peru, in order to measure a degree of the meridian near the equator. Ten years were spent in this operation, a full account of which was published by Bouguer in 1749, *Figure de la Terre determinée*. His later writings were nearly all upon the theory of navigation. He died in 1758.

The following is a list of his principal works:—*Traité d'optique sur la gradation de la lumière*, 1729 and 1760; *Entretiens sur la cause d'inclinaison des orbites des planètes*, 1734; *Traité de navire*, &c., 1746, 4to; *La Figure de la terre determinée*, &c., 1749, 4to; *Nouveau traité de navigation, contenant la théorie et la pratique du pilotage*, 1753; *Solution des principaux problèmes sur la manœuvre des Vaisseaux*, 1757; *Opérations faites pour la verification du degré du méridien entre Paris et Amiens*; par Mess. Bouguer, Camus, Cassini, et Pingré, 1757.

BOUHOURS, DOMINIQUE, a French critic, was born at Paris in 1628. He entered the Society of the Jesuits at the age of sixteen, and was appointed to read lectures on literature in the college of Clermont at Paris, and on rhetoric at Tours. He afterwards became preceptor to the two sons of the duke of Longueville. The duke died in Bouhours's arms; and the "account of the pious and Christian death" of this great personage was his first publication. He was sent to Dunkirk to the Romanist refugees from England, and in the midst of his missionary occupations published several books. Among these were *Les Entretiens d'Ariste et d'Eugène*, a work of a critical nature on the French language, printed five times at Paris, twice at Grenoble, and afterwards at Lyons, Brussels, Amsterdam, Leyden, &c. It involved him in numerous quarrels particularly with Ménage, who, however, continued to live on friendly terms with the author. The fame and [illegible] this piece recommended Bouhours so eff[illegible] great Colbert, that he intrusted him wit[illegible]

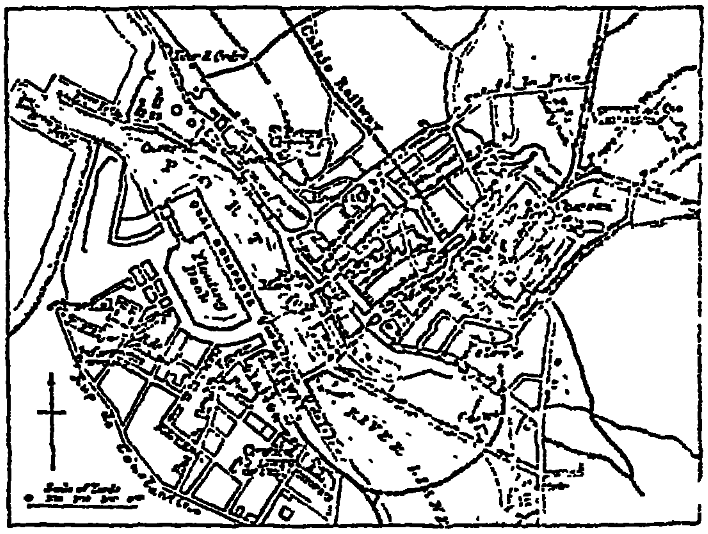
his son the marquis of Seignelay. He afterwards wrote several other works in French, the chief of which are, *La Manier de bien penser sur les ouvrages d'esprit*, 1687; *Remarks and Doubts upon the French Language*, 1694; *The Life of St Ignatius*, 1679; *The Art of Pleasing in Conversation; The Life of St Francis Xavier*, 1682. It was his practice to publish alternately a book on literature and a work on some subject of piety, which gave occasion to a wag, in a satirical epitaph, to remark of him, "qu'il servait le monde et le ciel par semestre." His *Pensées ingenieuses des Anciens et des Modernes*, though at once instructive and amusing, exposed him to censure as well as ridicule, on account of some strange misjudgments and omissions. He has classed Boileau with the least esteemed of the Italian satirical versifiers, and has omitted, in his *Thoughts on the Moderns*, all mention of Pascal,—a circumstance which is doubtless to be explained by his being a disciple of St Ignatius, who, it may be supposed, would willingly forget the author of the *Provincial Letters*. Bouhours died at Paris in 1702.

BOUILLON, Godfrey de, one of the foremost leaders in the first crusade, was born at Baisy, near Gemappe in Belgium, about 1060. His father was Eustace II., count of Bouillon in the Ardennes; and through his mother Ida, daughter of Godfrey, duke of Lower Lorraine, he could claim descent from Charlemagne. In the contest between Henry IV., emperor of Germany, and Hildebrand, he espoused the imperial cause, and was the first to scale the walls of Rome when the emperor's forces besieged that city in 1084. In reward for his services Henry invested him with the titles of marquis of Antwerp and duke of Lorraine. It is said that while suffering from fever, having heard of the preparations for the first crusade, he vowed, were his health restored, to seek Palestine; "whereupon," says William of Malmesbury, "he shook disease from his limbs, and shone with renovated beauty." Having pawned his lordship of Bouillon to the church of Liége for 1300 marks, he gathered around him 80,000 infantry and 10,000 horsemen, whom he led with rare ability through Germany to the borders of Hungary, where he shamed his brother Baldwin by offering to go in his stead as a hostage to the Hungarians. On arriving in 1096 at Constantinople, he obtained the release of his fellow-crusader Hugh of Vermandois from the wily Greek emperor Alexius, and in the strife which that monarch's duplicity fomented evinced the sagacity and promptitude of a great general. After capturing Antioch and routing a vast Saracen host at Dorylæum in Phrygia, the crusaders arrived, in 1099, at Jerusalem, which was taken after a siege of five weeks, Godfrey entering the breach among the foremost, but tarnishing his glory by ruthlessly ordering a massacre of the infidels. A Christian kingdom of Jerusalem was then founded, of which Godfrey was unanimously elected sovereign; but he refused to wear a crown of gold where his Lord had worn a crown of thorns, and accepted, instead of the kingly title, the humbler designation of defender and baron of the Holy Sepulchre. During the single year of his rule he repelled the Saracens with admirable courage and skill, routing the Fatimite caliph of Egypt at Ascalon, and with the assistance of others of the pilgrims, drew up from the various feudal statutes of Europe the elaborate system of mediæval jurisprudence known as the *Assizes of Jerusalem*. Godfrey died in 1100, and was buried in the church of the Holy Sepulchre; and so impartial and temperate had been his rule, that Mahometans as well as Christians bewailed his loss. He combined the favourite virtues of his age; and his exploits, in the quaint words of Gregory de Vinsauf, "were as food in the mouths of their narrators." He was as accomplished as brave, and could speak the Latin and Teutonic languages with equal ease. Tasso, in the *Gerusalemme Liberata*, makes Godfrey the equal of Tancred in the field and of Raymond in the council, and seems scarcely to have exaggerated his heroism and skill in war, his piety, wisdom, and purity of life.

BOULAINVILLIERS, Henri de, Lord of St Saire, an eminent French writer, descended from a very ancient and noble family, was born at St Saire in Normandy in 1658. He received his education at the college of Juilli, where he early discovered the uncommon abilities for which he was afterwards distinguished. His historical writings are numerous and important, but deformed by an extravagant admiration of the feudal system, which he regarded as the *chef d'œuvre* of the human mind. He misses no opportunity of regretting those "good old times," when the people were enslaved by a few petty tyrants alike ignorant and barbarous. His philosophical writings have now lost all their value. His pretended *refutation* of the system of Spinoza is a weak and imperfect exposition of that writer's opinions. He died at Paris in 1722.

His principal works (all published after his death) are—*Histoire de l'ancien gouvernment de la France*, &c., La Haye, 1727, 3 tom. 8vo; *État de la France, avec des mémoires sur l'ancien gouvernment*, &c., Lond., 1727, 3 tom. fol.; *Histoire de la Pairie de France*, &c., Lond., 1753; *La Vie de Mahomet* (a "Fable of Mahomet," as Mosheim calls it); *Histoire des Arabes*, Amst. (Paris), 1731, 2 vols. 12mo.

BOULOGNE SUR MER, a fortified seaport of France, and the chief town of an arrondissement in Pas-de-Calais,



Plan of Boulogne.

1, 2, 3. Etablissement,—Including Baths, Aquarium, and Skating Rink.

16. Market House.
17. Theatre.
18. English Church.
19. Place St Sauveur

Dame, built (1827–1866) on the site of an old building destroyed in the Revolution, having underneath an extensive crypt which still remains. The New Town extends from the foot of the hill to the harbour and along the shore, and contains several good streets, some of which are, however, very steep. A main street, named successively Rue de la Lampe, St Nicholas, and Grande Rue, extends from the bridge across the Liane (near the railway station) to the promenade by the side of the ramparts and the Hôtel de Ville. This is intersected first by the shore-way named *Quai de la Flotille*, *Quai de la Victoire*, &c. (where there are numerous hotels), and further back by the Rue Napoléon and Rue Royale, the principal business part of the town, and where the best shops are situated. The principal buildings comprise a museum, formerly the great seminary, a hospital, a theatre, an elegant *établissement* (opened in 1863, containing ball-room, reading-room, &c.), a custom-house, barracks, various churches and convents, and a fish-market. Connected with the museum is a public library with 30,000 volumes and a large number of very valuable manuscripts, many of them richly illuminated. Boulogne has for a long time been one of the most Anglicized of French cities; and in the tourist season a continuous stream of English travellers reach the Continent at this point. There is regular steamboat service between the port and Folkestone, the average passage occupying 2¼ hours, or about three-quarters of an hour longer than from Calais to Dover. There are two English chapels in the town, and numerous boarding-schools intended for English pupils. Churchill, who died while on a visit to his friend Wilkes, in 1765, is buried in the cemetery, and the house is pointed out where Thomas Campbell expired in 1843. The shore is lined with extensive flat sands, where bathing is facilitated by the use of machines. Among the objects of interest in the neighbourhood the most remarkable is the Napoleon column or Colonne de la Grande Armée, erected on the high ground above the town, in honour of Napoleon I., on occasion of the projected invasion of England, for which he here made great preparations. The pillar, which is of the Doric order, 166 feet high, is surmounted by a statue of the emperor by Bosio. Though commenced in 1804, the monument was not completed till 1841. On the edge of the cliff to the east of the port are some rude brick remains of an old building called Tour d'Ordre, said to be the ruins of a tower built by Caligula at the time of his intended invasion of Britain. The entrance to the harbour of Boulogne, which is tidal, is formed by two long piers running out from the mouth of the river, and serving during fine weather as excellent promenades. On the western side is the basin excavated by Napoleon for his flotilla of flat-bottomed boats in 1804. A large wet dock, constructed at a cost of upwards of £250,000, was opened in 1872, and adds greatly to the facilities of the port, its area being 17 acres and the length of its quay-wall 1150 yards. The depth of water in the harbour is 23 feet at spring-tide and nearly 20 at neap-tide; in the sluice of the floating basin the numbers are 29½ and 23½ respectively. The foreign commerce of Boulogne, which is almost wholly carried on in British ships, consists chiefly in the importation of manufactured goods, jute, silk, Australian wool, coal, machinery, hardwares, paper-hangings, malt, beer, and chemicals; and the exportation of wine, brandy, eggs, artificial flowers, haberdashery, and musical instruments. The total value of the exports in 1871 was £12,709,675, and of the imports £11,762,500. How rapid the development of the commerce with Britain has been may be seen from the fact, that while in 1840 the British sailing vessels thus engaged amounted only to 66, and the steam-ships to 678, in 1860 the corresponding numbers were 341 and 863, and in 1871, 541 and 1061. In the extent and value of its fisheries Boulogne is exceeded by no seaport in France. The most important branch is the herring-fishery, which is prosecuted northwards along the shores of Scotland; next in value is the mackerel fishery, and next again the Iceland cod. Large quantities of fresh fish are transmitted to Paris by railway, but an abundant supply is reserved to the town itself. The fishermen live for the most part in a separate quarter called La Beurière. Among the numerous industrial establishments in Boulogne and its environs may be mentioned several foundries, with blast-furnaces, cement-manufactories, flax-mills, steam saw-mills, steel-pen manufactories, carriage-works, tile-works, and a fishing-net factory. Shipbuilding is also carried on to some extent. The population of the town, which in 1821 was 16,607, amounted by the census of 1872 to 39,700.

Boulogne is usually, though on somewhat dubious grounds, identified with the *Gesoriacum* of the Romans. At an early period it began to be known as *Bononia*, a name which has been gradually modified into the present form. The town was destroyed by the Normans in 882, but restored about 912. From about that time till 1477 it was the head of a separate countship, which was united to the crown of France by Louis XI., who ingeniously recognized the Holy Virgin as the superior, and declared himself her vassal. In 1544 Henry VIII.—more fortunate in this than Henry III. had been in 1347—took the town by siege; but it was restored to France in the following reign.

BOULTON, Matthew, manufacturer and practical engineer, was born at Birmingham on the 14th of September 1728. He was called early into active life upon the death of his father in 1745, and soon found ample scope for the exercise of his inventive faculties in improving the manufactures of his native place. His first attempt was a new mode of inlaying steel; and he succeeded in obtaining a considerable demand for the products of his manufactory, which were principally exported to the Continent, and not uncommonly re-imported for domestic use as of foreign manufacture.

In 1762, his fortune being already considerable, he purchased a tract of barren heath in the neighbourhood of Birmingham, with a single house on it, and there founded, at the expense of £9000, the manufactory which flourished so long and was so well known under the name of Soho. His workmen were at first principally employed in the imitation of ormolu, and in copying oil paintings with great accuracy, by means of a mechanical process which was invented by a Mr Eggington, who afterwards distinguished himself by various works in stained glass. Boulton finding the horse-power inadequate to the various purposes of his machinery erected, in 1767, a steam-engine, upon the original construction of Savary, which, notwithstanding the inconvenience of a great loss of steam from condensation, by its immediate contact with the water raised, has still some advantages from the simplicity of the apparatus it requires, and has been found to succeed well upon a small scale. But Boulton's objects required a still more powerful machine, and he had the discernment to perceive that they might be very completely attained by the adoption of the various improvements made in the steam-engine by James Watt of Glasgow, who had obtained a patent for them in 1769, the privileges of which were extended in 1775, by an Act of Parliament, to a term of twenty-five years. Boulton induced the great inventor to remove to Birmingham. They commenced a partnership in business, and established a manufactory of steam-engines, in which accurate execution kept pace so well with judicious design, that its productions continued to be equally in request with the public after the expiration of

the term of that legal privilege which at first gave the proprietors the exclusive right of supplying them, and which had been confirmed in 1792 by a decision of the Court of King's Bench against some encroachment on the right of the patentee. It was principally for the purpose of carrying on this manufactory with greater convenience, that the proprietors established an iron-foundry of their own at Smethwick, in the neighbourhood of Soho.

In 1785 Boulton was made a fellow of the Royal Society, about the same time with Withering, and several others of his scientific neighbours. In 1788 he turned his attention to the subject of coining, and erected machinery for the purpose, so extensive and complete, that the operation was performed with equal economy and precision, and the coins could not be imitated by any single artist for their nominal value,—each of the stamps coining, with the attendance of a little boy only, about eighty pieces in a minute. The preparatory operation of laminating and cutting out the metal was performed in an adjoining room; and all personal communication between the workmen was rendered unnecessary by the mechanical conveyance of the work from one part of the machinery to another. A coinage of silver was executed at this mint for the Sierra Leone Company, and another of copper for the East Indies, besides the pence and half-pence at one time in circulation throughout England, and a large quantity of money of all kinds for Russia. In acknowledgment of Boulton's services, and in return for some specimens of his different manufactures, the Emperor Paul made him a present of a valuable collection of medals and minerals.

In 1797 he obtained a patent for a mode of raising water by impulse, the specification of which is published in the ninth volume of the *Repertory of Arts*, p. 145. It had been demonstrated by Daniel Bernouilli, in the beginning of the century, that water flowing through a pipe, and arriving at a part in which the pipe is suddenly contracted, would have its velocity at first very greatly increased; but no practical application of the principle appears to have been attempted, until an apparatus was set up in 1792 by Mr Whitehurst for Mr Egerton of Oulton, in Cheshire, consisting of an air-vessel communicating with a water-pipe by a valve, which was forced open by the pressure or rather impulse of the water, when its passage through the pipe was suddenly stopped by turning the cock in the ordinary course of domestic economy; and although the pipe through which the water was forced up was of moderate height, the air-vessel, which was at first made of lead, was soon burst by the "momentous force," as Whitehurst termed it. The apparatus had excited much attention in France, under the name of Montgolfier's hydraulic ram; and Boulton added to it a number of ingenious modifications, some of which, however, are more calculated to display the vivid imagination of a projector than the sound judgment of a practical engineer, which had in general so strongly characterized all his productions.

He died, August 17, 1809, after a long illness, in possession of considerable affluence and of universal esteem. (See Smiles's *Lives of Boulton and Watt*, 1865.)

BOURBON. The noble family of Bourbon, from which so many European kings have sprung, took its name from the rich district in the centre of France, called the *Bourbonnais*, which in the 10th century was one of the three great baronies of the kingdom. The first of the long line of Bourbons known in history was Adhémar or Aimar, who was invested with the barony towards the close of the 9th century. In 1272 Beatrix, daughter of Agnes of Bourbon and her husband John of Burgundy, married Robert, count of Clermont, sixth son of Louis IX. (St Louis) of France. The elder branches of the family had become extinct, and their son Louis became duc de Bourbon in 1327. In 1488 the line of his descendants ended with Jean II., who died in that year. The whole estates passed to Jean's brother Pierre, lord of Beaujeu, who was married to Anne, sister of Louis XI. Pierre died in 1503, leaving only a daughter, Suzanne, who, in 1505, married Charles de Montpensier, heir of the Montpensier branch of the Bourbon family. Charles, who took the title of duc de Bourbon on his marriage, was born in 1489, and at an early age was looked upon as one of the finest soldiers and gentlemen in France. His union with Suzanne made him the wealthiest and most powerful French noble; and after his brilliant successes in Italy and France, he became an object of dread to Louis XII., who would not give him the command of the army of Italy. In 1515 Francis I., on his accession, made Bourbon constable of France, and in that capacity he gained new honours, and was for a time in the highest favour with the king. But serious differences soon arose between them, originating, according to common report, in the violent but slighted passion of Louise, duchesse d'Angoulême, the king's mother, for the constable. The grossest insults were heaped upon Bourbon; his official salary and the sums he had borrowed for his war expenses remained unpaid; in the campaign against Charles V. the command of the vanguard was given to the duc d'Alençon; and after the death of Suzanne de Bourbon, an action was raised by the queen dowager, who claimed to be nearest heir. In defiance of Bourbon's marriage-settlement, judgment was given against him, and he was reduced to absolute beggary. Smarting under these wrongs he entered into negotiations with Charles V., and on these coming to the knowledge of Francis at once fled from his native country and joined the emperor. He did good service in the war against his countrymen, and especially distinguished himself at the battle of Pavia, where his ungenerous sovereign Francis was taken prisoner. Bourbon, however, did not find Charles very ready to fulfil his various promises, and determined to seize a kingdom for himself. With the division under his command he penetrated into Italy, and on the 5th May 1527 appeared before the walls of Rome. In the assault on the following morning he was the first to mount the walls, and fell mortally wounded by a pistol-shot, fired, it is said, by Benvenuto Cellini. His army succeeded in taking and sacking the town. With the constable ended the direct line from Pierre, duc de Bourbon. But the fourth in descent from Pierre's brother, Jacques, Louis, count of Vendôme and Chartres, became the ancestor of the royal house of Bourbon and of the noble families Condé, Conti, and Montpensier. The fourth in direct descent from Louis of Vendome was Antoine de Bourbon, who in 1548 married Jeanne d'Albret, heiress of Navarre, and who became king of Navarre in 1554. Their son became king of France, with the title Henri IV. Henri was succeeded by his son Louis XIII., who left two sons, Louis XIV., and Philippe, duc d'Orleans, head of the Orleans branch. Louis XIV.'s son, the Dauphin, died

Philippe, has descended another claimant of the throne. Philippe's son was the Regent Orleans, whose great grandson, Philippe Egalité, perished on the scaffold in 1793. Egalité's son, Louis Philippe, was king of France from 1830 to 1848; his grandson, Louis Philippe (born 1838), is the present Comte de Paris.

Spanish Branch.—Philippe, duc d'Anjou, grandson of Louis XIV., became king of Spain as Philip V. in 1700. He was succeeded in 1746 by his son Ferdinand VI., who died in 1759 without family, and was followed by his brother Charles III. Charles III.'s eldest son became Charles IV. of Spain in 1788, while his second son, Ferdinand, was made king of the Two Sicilies in 1759. Charles IV. was deposed by Napoleon, but in 1814 his son, Ferdinand VII., again obtained his throne. Ferdinand was succeeded by his daughter Isabella, who in 1870 abdicated in favour of her son Alphonso, at present (1876) in possession of the Spanish kingdom. Ferdinand's brother, Don Carlos (died 1855), claimed the throne in 1833 on the ground of the Salic law, and a fierce war raged for some years in the north of Spain. His son Don Carlos, count de Montemolin (born 1818, died 1861) revived the claim, but was defeated and compelled to sign a renunciation. The nephew of the latter, Don Carlos Maria Juan Isidor (born 1848), has been for some years carrying on war in Spain with the object of attaining the rights contended for by the Carlist party.

Neapolitan Branch.—The first Bourbon who wore the crown of Naples was Charles III. of Spain, who on his succession to the Spanish throne in 1759, resigned his kingdom of Naples to his son Ferdinand. Ferdinand was deposed by Napoleon, but afterwards regained his throne, and took the title of Ferdinand I., king of the Two Sicilies. In 1825 he was succeeded by his son Francis, who in turn was succeeded in 1830 by his son Ferdinand II. Ferdinand II. died in 1859, and in the following year his successor Francis II. was deprived of his kingdom, which was incorporated into the gradually-uniting Italy.

Duchies of Lucca and Parma.—In 1748 the duchy of Parma was conferred on Philip, youngest son of Philip V. of Spain. His grandson, Charles Louis Ferdinand, became king of Etruria in 1801, but was deprived of his possessions by the French. In 1847, however, he received the duchies of Parma and Piacenza on the death of his mother, but after two years abdicated in favour of his son, Charles III. Charles III. married the daughter of the duc de Berri, and was assassinated in 1854. His son was proclaimed duke, but the territories of Parma and Piacenza were seized by Victor Emanuel in 1859–60.

Coiffier de Moret, *Histoire du Bourbonnais et des Bourbons*, 2 vols. 1824; Berand, *Histoire des sires et ducs de Bourbon*, 1835; Désormeaux, *Histoire de la maison de Bourbon*, 5 vols., 1782–88; Achaintre, *Histoire généalogique et chronologique de la maison royale de Bourbon*, 2 vols., 1825–6.

BOURBON, an island off the east coast of Africa, now known as Réunion. See Réunion.

BOURBON-L'ARCHAMBAULT (the *Aqua Bormonis* of the Itineraries), a town of France, in the department of the Allier, on the Burge, 19 miles W. of Moulins. It was anciently the capital of the Bourbonnais, and gave its name to the great Bourbon family. Its mineral waters, both hot and cold, were formerly in high repute. In 1789 it changed its name for that of *Burges-les-Bains*, but the former designation was afterwards resumed. It contains a Gothic church of the 12th century, and the outer walls and towers of a castle finished by Anne of Beaujeu in the 15th. Population in 1872, 2400.

BOURBON-VENDÉE, or Napoleon Vendée, a town of France, capital of the department of La Vendée, now called La Roche sur Yon, which see.

BOURBONNE-LES-BAINS, a town of France, in the department of Haute-Marne, in the arrondissement of Langres, and 21 miles E.N.E. of that town. It is much frequented on account of its hot saline springs, which are found on the site of the old Roman baths. The heat of these springs varies from 120° to 156° Fahr. The number of visitors is upwards of 800 annually. The principal buildings are a church of the 13th century, the town-house, and the hospital; there are also the remains of a castle and a priory. The manufacture of beet-root sugar is carried on in the town, and gypsum and alabaster are quarried in the neighbourhood. Population in 1872, 4038.

BOURCHIER, John, Lord Berners, born about 1474, was grandson and heir of a lord of the same name, who was descended from Thomas of Woodstock, duke of Gloucester, and had been knight of the Garter and constable of Windsor Castle. He was educated at Oxford, and was created a Knight of the Bath on the marriage of the duke of York, second son of Edward IV. He was first known by quelling an insurrection in Cornwall and Devonshire, raised by Michael Joseph, a blacksmith, in 1495, which service recommended him to the favour of Henry VII. He was a captain of the pioneers at the siege of Therouanne under Henry VIII., by whom he was made chancellor of the exchequer for life, and lieutenant of Calais and the Marches. He was appointed to conduct Mary, the king's sister, into France on her marriage with Louis XII., and had the extraordinary fortune of continuing in favour with Henry VIII. for the space of eighteen years. He died at Calais in 1532, aged 65. By king Henry's command he translated Froissart's *Chronicle*, which was printed in 1523 and 1525 by Pynson, the scholar of Caxton. His other works consisted of translations from French, Spanish, and Italian novels. These were, the *History of the most Noble Valyaunt Knyght, Arthur of Lytell Brytayne; the Famous Exploits of Sir Hugh of Bourdeaux; the Golden Boke of Marcus Aurelius;* and *the Castle of Love.* He composed also a book on the duties of the inhabitants of Calais, and a comedy entitled *Ite in Vineam*, which used to be acted at Calais after vespers.

BOURDALOUE, Louis, a celebrated preacher, and one of the greatest orators that France has ever produced, was born at Bourges, August 20, 1632. At the age of sixteen he entered the Society of Jesus, of which he was destined to become one of the greatest ornaments, and there completed his studies. His able masters, who early discerned his talents, successively confided to him the chairs of humanity, of rhetoric, of philosophy, and of moral theology; and it was only after passing through these different probationary employments that he arrived at the eminent post which was designed for him, and was deemed qualified for mounting the pulpit.

In order to form an idea of the difficulties which he had to surmount, and of the talents which he displayed, it is only necessary, on the one hand, to call to mind the ridiculous manner and inflated style of the preachers of that period; and on the other, to figure the young Jesuit at issue with the bad taste as well as the bad habits of the time,—combating at once the passions, the vices, the weaknesses, and the errors of humanity, and overcoming his enemies, sometimes with the arms of faith, and sometimes with those of reason.

At first he preached for some time in the provinces, but his superiors afterwards called him to Paris. This took place in 1669, at the most brilliant epoch of the age of Louis XIV., when nothing was talked of but the victories of Turenne, the festivities of Versailles, the masterpieces of Corneille and Racine, the encouragement afforded to the arts, and the general impulse given to the human mind. Bourdaloue suddenly appeared in the midst of these fasci-

nations, and, far from diminishing their effects, the severity of his ministry and the gravity of his eloquence served rather to enchance their splendour. His first sermons met with prodigious success, and all voices were raised in loud applause of the preacher. Madame de Sevigné, sharing the universal enthusiasm, wrote to her daughter that "she had never heard anything more beautiful, more noble, more astonishing, than the sermons of Father Bourdaloue." Louis XIV. also wished to hear him, and the new preacher was in consequence sent to court, where he preached during Advent in 1670, and during Lent in 1672; and he was afterwards called for the Lents of 1674, 1675, 1680, and 1682, and for the Advents of 1684, 1689, and 1693. This was a thing unheard of before, the same preacher being rarely called three times to court. Bourdaloue, however, appeared there ten times, and was always received with the same ardour. Louis XIV. said that "he loved better to hear the repetitions of Bourdaloue than the novelties of any one else." After the revocation of the Edict of Nantes he was sent to Languedoc to preach to the Protestants, and confirm the newly-converted in the Catholic faith; and in this delicate mission he managed to reconcile the interests of his ministry with the sacred rights of humanity. He preached at Montpellier in 1686 with the greatest success, Catholics and Protestants being all equally eager to recognize in this eloquent missionary the apostle of truth and of virtue.

In the last years of his life Bourdaloue abandoned the pulpit, and devoted himself to charitable assemblies, hospitals, and prisons, where his pathetic discourses and conciliatory manners were very effective. He had the art of adapting his style and his reasonings to the condition and the understanding of those to whom he addressed either counsel or consolation. Simple with the simple, erudite with the learned, and a dialectician with sophists and disputants, he came off with honour in all the contests in which zeal for religion, the duties of his station, and love of mankind led him to engage. Equally relished by the great and by the commonalty, by men of piety, and by people of the world, he exercised till his death in 1704 a sort of empire over all minds; and this ascendency he owed as much to the gentleness of his manners as to the force of his reasoning. "His conduct," says one of his contemporaries, "is the best answer that can be made to the *Lettres Provinciales*." No consideration was ever capable of altering his frankness or corrupting his probity.

Bourdaloue may with justice be regarded as the reformer of the pulpit and the founder of Christian eloquence among the French. That which distinguishes him from other preachers is the force of his reasoning, and the solidity of his proofs. Never did Christian orator infuse into his discourses more majesty, dignity, energy, and grandeur. Like Corneille, he has been charged with overlabouring his diction, and accumulating idea upon idea with a needless superfluity of illustration—of speaking more to the understandings than to the hearts of his auditors, and sometimes enervating his eloquence with the too frequent use of divisions and subdivisions. But even in subscribing to these criticisms, which are to a certain extent well founded, it is impossible not to admire the inexhaustible fecundity of his plans—the happy talent *velut imperatoria virtus* which he possessed, of disposing his reasonings in the order best calculated to command victory—the logical skill with which he excludes sophisms, contradictions, and paradoxes—the art with which he lays the foundations of our duty in our interest—and, finally, the inestimable secret of converting the details of manners and habits into so many proofs of his subject. Parallels have often been drawn between Bourdaloue and Massillon; but the talents of these great pulpit orators lay in different directions, and they may, therefore, be more fitly contrasted than compared. "Between Massillon and Bossuet," says Lord Brougham, whose judgment of Bossuet errs, however, on the side of severity, (*Works*, vol. vii.), "and at a great distance certainly above the latter, stands Bourdaloue, whom some have deemed Massillon's superior, but of whom an illustrious critic (D'Alembert, *Éloge de Massillon*) has more justly said that it was his greatest glory to have left the supremacy of Massillon still in dispute. It is certain that he displays a fertility of resources, an exuberance of topics, whether for observation or argument, not equalled by almost any other orator, sacred or profane." If Massillon is now read with a more lively interest, he owes that advantage to the charms of his style rather than to the force of his reasoning. Among the critics of the present day, the preference is unhesitatingly given to the rival of Racine, to the painter of the heart, to the author of the discourse on the small number of the elect; but if we consult the contemporaries of Massillon himself, we shall find that they assign him only the second rank. According to them Bourdaloue preached to the men of a vigorous and masculine age—Massillon to those of a period remarkable for its effeminacy. Bourdaloue raised himself to the level of the great truths of religion—Massillon conformed himself to the weakness of the men with whom he lived. The bishop of Clermont will always be read; but if the simple Jesuit could raise his commanding voice from the tomb, and again roll forth a majestic stream of divine truth, the courtly accents of his rival would no longer be heard, and the charms of his diction would be forgotten. The first part of his celebrated *Passion*, in which he proves that the death of the Son of God is the triumph of His power, has generally been considered as the great masterpiece of Christian eloquence. Bossuet has said nothing stronger or more elevated. The second part, however, is inferior to the first, though considered by itself alike beautiful and convincing.

The discourses of Bourdaloue have been described by a celebrated French critic as embodying in them a complete course of theology. This is perhaps going a little too far; but still their general merit is very great, and for nothing are they more distinguished than their comprehensiveness. The diction of this great preacher is always natural, clear, and correct, sometimes deficient in animation, but without vacuity or languor, and generally relieved by outbreakings of much force and originality.

Two editions of Bourdaloue's works were published at

for the richness of its sculpture and carving. Two of the squares of the town are ornamented, one with a statue of Bichat by David d'Angers, and the other by an obelisk to the memory of General Joubert. The manufactures of the place consist of cloth, linen, hats, hosiery, horn combs, and pottery; and there is an active trade in grain, cattle, horses, and wine. The early history of Bourg and its identification with any of the places recorded by the Roman writers have been matters of considerable dispute. In the earlier part of the Middle Ages it seems to have been called *Tanum*. Raised to the rank of a free town in the end of the 13th century, it was afterwards chosen by Amadeus IV. of Savoy as the chief city of the province. In 1535 it passed to France, but was restored to Duke Philibert Emanuel, who in 1590 built a strong citadel, which afterwards withstood a six months' siege by the soldiers of Henry IV. The town was finally ceded to France in 1601. In 1814 the inhabitants, in spite of the defenceless condition of their town, offered resistance to the Austrians, who put the place to pillage. Vaugelas the grammarian and Lalande the astronomer were both born at Bourg-en-Bresse. Population in 1872, 12,912.

BOURGAS, BURGHAZ, or BORGAS, called in the Middle Ages Pyrgos, a seaport town of Turkey in the province of Rumelia, situated on a bay of the Black Sea, to which it gives its name, about 70 miles N.E. of Adrianople, in 42° 30′ N. lat. and 27° 30′ E. It is neatly built, and has a large public square surrounded with stalls for the accommodation of 5000 horses. Pottery and pipes are manufactured with great taste from clay obtained in the neighbourhood, and there is a considerable trade in grain, woollen stuffs, tallow, butter, cheese, rosewater, and other productions of the surrounding country. Not far distant is Litzin, a favourite summer watering-place. In 1825 the Russians besieged the town. The population is estimated at 5000.

BOURGELAT, CLAUDE, who may be called the father of veterinary science, was born at Lyons in 1712, and died in 1799. He entered the profession of law, but abandoned it in disgust at having gained an unjust suit for a client. Embracing the military profession he served in the cavalry, and thus had ample opportunity of studying the diseases of animals. In 1772 he opened at Lyons a veterinary school, which soon became celebrated over Europe. His great success induced the Government to establish several similar institutions; and Bourgelat was appointed to superintend the school established at Alfort, which became, and continues to be, the chief seat of veterinary science in France. Bourgelat was a member of the Academies of Sciences of Paris and of Berlin, and corresponded with some of the most eminent men of science of his time. His works on veterinary subjects are numerous and valuable; perhaps the most important is the *Traité de la conformation extérieure du cheval, de sa beauté et de ses défauts*, 1776.

BOURGES, a city of France, formerly the capital of the province of Berry, and now the chief town of the department of Cher, is situated about 100 miles S. of Paris, at the confluence of the Auron and Yevre, in 47° 4′ 59″ N. lat. and 2° 32′ E. long. The sixty watch-towers by which it was formerly defended have been removed, but it is still surrounded by ramparts laid out as promenades, and its streets are remarkable for the numerous specimens which they preserve of mediæval architecture. The cathedral, which dates in its earlier portions from the 13th century, is regarded as one of the finest in France, and the Hôtel de Ville, originally the house of Jacques Cœur, the famous jeweller under Charles VII., is a splendid example of the florid style of the 15th century. The house of the Lallemant family, built about 1520, that of Cujas, the famous jurist, dating from the 16th century, and now used as barracks for the *gendarmerie*, and the gate of Saint Ours, are also worthy of notice. The archiepiscopal palace, the great prison, and the *grand seminaire*, now converted into cavalry barracks, are the most important of the other buildings. There are also in the town a museum, a large public library, and a number of colleges. A certain amount of trade is carried on in grain, hemp, wood, skins, wool, and cattle; and cloth, leather, and cutlery are manufactured. There are also several breweries, and the nurseries in the neighbourhood are famous. In 1861 the city became the seat of a military arsenal, which is now of considerable importance. The population, stated at 22,465 in 1851, amounted in 1872 to 27,377. Bourges occupies the site of the Gallic town of *Avaricum*, mentioned by Cæsar as one of the most important of all Gaul. In 52 B.C., during the war of Vercingetorix, it was completely destroyed by the Roman conqueror, but under Augustus it rose again into importance, and was made the capital of Aquitania Prima. In 252 A.D. it became the seat of a bishop, the first occupant of the see being Ursinus. Captured by the Goths in 475, it continued in their possession till about 507. During the English occupation of France in the 15th century it became the residence of Charles VII., who thus acquired the popular title of king of Bourges. In 1463 a university was founded in the city by Louis XI., which continued for centuries to be one of the most famous in France, especially in the department of jurisprudence. On seven different occasions Bourges was the seat of ecclesiastical councils,—the most important being the council of 1438, in which the Pragmatic Sanction of the Gallican Church was established, and that of 1528 in which the Lutheran doctrines were condemned.

BOURIGNON, ANTOINETTE, a singular enthusiast of the 17th century, who excited considerable commotion by her religious doctrines, but whose name is now almost forgotten. She was born at Lille in the beginning of 1616; and her appearance as an infant was so deformed that the question of preserving her alive was seriously discussed. She manifested, while still very young, an extraordinary spirit of religious fervour, fostered, apparently, by her loneliness and the neglect of her parents. As she grew up this spirit increased in intensity. So few, it seemed to her, lived according to their professed Christian principles that she desired to be carried into the Christian countries. The unhappiness that she observed at home, from the severity of her father to her mother, gave her an invincible repugnance to marriage,—so much so that when it was desired that she should marry at the age of twenty she fled from her father's house in disguise. Her disguise, however, was soon discovered, and having fallen into the hands of a soldier, she ran worse risks than if she had remained to face her destiny at home. Her autobiography dwells upon these and other similar events of her life, when her virtue underwent violent assault, which she was happily able to resist. She is said to have been "endowed with a wonderful chastity, which remained unassailable by all force or enticement, and which not only preserved her own person pure, but diffused around her an ardour of continence."

Having been delivered from the hands of the soldier into which she had fallen in her wanderings, she became known to the archbishop of Cambray, under whose sanction she established a small society of nuns. She soon, however, became restless in her new occupation, in which she does not seem to have been successful. The archbishop withdrew his countenance, and for a time she returned to her native country, where she is said to have "passed many years in privacy and in a great simplicity of life." On the death of her parents she became entitled to some fortune, which she at first declined, but afterwards took possession of. She seems then to have become the head of a hospital at Lille for some time (1653, *et seq.*), but scandal having broken out in connection with it, she left and fled to Ghent (1662).

Here, apparently, she entered upon the higher prophetic phase of her life. "God revealed great secrets to her," which she began to proclaim; and soon she gathered around her a few ardent disciples. Her prophetic views were specially expounded in one of her books published at this time at Amsterdam, entitled *The Light of the World*. Some of her disciples formed the design of settling in the island of Noordstrand in Holstein. At first she seems to have declined to join them, but afterwards set out for the purpose. She did not remain long, disturbances having arisen not only against her opinions, but in the ranks of her own followers. She was evidently impatient of sharing her influence with any one, and is said to have been of very difficult and self-willed temper. She returned to Holland, and died there in 1680.

It is difficult to give any estimate of A. Bourignon's character and opinions. So far as appears, she was a visionary of the ordinary type, only distinguished by the rare persistency and audacity of her pretensions. Amidst all her enthusiasm she seems to have known how to look after her own interests. She is said never to have given alms to the poor, not even to the hospital which she superintended. She was willing to assist with her hand, but not with her money. Her main idea about religion was that it was a mere internal ecstasy, independent of both church and Bible. She had innumerable visions, from which source she chiefly drew her religious inspiration and knowledge. Among others she saw in vision Antichrist and Adam before the Fall; and she describes the appearance of the former minutely, even to the colour of his hair. Her visions and views she gave to the world in numerous treatises and pamphlets.

Her followers in Holland seem to have dwindled rapidly away, if they ever had any of the life of a distinct sect; but, strangely, her influence revived in Scotland in the beginning of the 18th century, so much so as to be a source of alarm to the Presbyterian Church, and to call forth not only one but several Acts of the General Assembly in denunciations of her doctrines and earnest caution against their contagion. These Acts are found severally in 1701, 1709, and 1710; and even at this last date it is alleged that "the gross heresies and errors going under the name of Bourignianism are greatly prevailing in the bounds of the national church." This is the explanation, no doubt, of the fact that Bourignianism is amongst the heretical sects which the clergy of the Church of Scotland are taken bound to "disown" at their ordination in a series of questions appointed to be put in 1711. The very name, however, is now generally unknown in Scotland, notwithstanding this strange survival of it; and should any one turn to the Act of Assembly of 1701, which professes to enumerate the opinions of M. Antonia Bourignon, and describes them as "impious, pernicious, and damnable," he will hardly get more light as to the nature of these opinions than elsewhere. They present an unintelligible conglomeration without coherency or order,—such subjects as the denial of election, the permission of sin, and the bondage of the will being mixed up with the quality of Christ's human nature, the perfection of the present life, and "that generation takes place in heaven, and that there are no true Christians in the world." Mlle. Bourignon's works were published in French at Amsterdam in 1686, in 19 vols. 8vo. Her *Vie extérieure*, by herself, to be found in the first volume is the chief authority for the earlier part of her life. *La Vie continuée de Mlle. Bourignon*, which occupies the whole of the second volume (author's name not given), treats of her life at length, but in a semi-legendary manner. Three of her works at least have been translated into English.—*An Abridgment of the Light of the World*, London, 1786; *A Treatise of Solid Virtue*, 1699; *The Restoration of the Gospel Spirit*, 1707.

BOURNE, Vincent, one of the most able modern writers of Latin verse, was born at Westminster towards the close of the 17th century. In 1710 he became a scholar at Westminster school, and in 1714 entered Trinity College, Cambridge. He graduated in 1717, and obtained a fellowship three years later. Of his after life exceedingly little is known. It is certain that he passed the greater portion of it as usher in Westminster school. He died on 2d December 1747. During his lifetime he published several small collections of his Latin poems, and in 1772 there appeared a very handsome 4to volume containing all Bourne's pieces, but also some that did not belong to him. The Latin poems are remarkable not only for perfect mastery of all linguistic niceties, but for graceful expression and genuine poetic feeling. A number of them are translations of English poems, and it is not too much to say that the Latin versions almost invariably surpass the originals. Cowper, an old pupil of Bourne's, Beattie, and Lamb have combined in praise of his wonderful power of Latin versification.

BOURNEMOUTH, a watering-place in the south of England, situated on the Hampshire coast about five miles from Christchurch. Its sheltered situation and desirable winter climate began to attract notice about 1840; and now it possesses five or six hotels, several churches, a library and reading-room, assembly-rooms, baths, and the usual accompaniments of a frequented watering-place. In 1855 a sanatorium for consumptive patients was erected by subscription, and various establishments of a similar nature have since been founded. A pier 800 feet long was opened in 1861, and in 1870 railway communication was afforded by a branch of the South-Western from Ringwood. The climate is remarkable for the equability of its temperature. According to observations from 1862 to 1872 the average maximum by day in July is 71°·9, and the average minimum by night in January 35°·6. The rainfall is about 30 inches in the course of the year, and the subsoil carries off water with great readiness. The surrounding country is extremely beautiful; and the buildings of Bournemouth itself are picturesquely disposed on the slope of a richly wooded hill. Population in 1871, 5906.

BOURRIENNE, Louis Antoine Fauvelet de, the early friend and biographer of Napoleon, was born at Sens in 1769. His friendship with Napoleon began at the military academy of Brienne, where they were class-fellows, but they did not meet for some time after leaving school, as Bourrienne's humble birth precluded him from military service. In 1789, having embraced the career of diplomacy, he was sent as attaché to Vienna, and thence proceeded to Leipsic where he studied for some time. In 1792 he returned to Paris and renewed his close acquaintance with Bonaparte. Towards the close of the same year he was sent as Secretary of Legation to Stuttgart, but the fall of the monarchy a few months later threw him out of office. He was imprisoned for a short time by the Saxon Government as an adherent of the Revolution, and did not return to Paris till 1795. In the following year, after a slight coldness between the friends, Napoleon invited Bourrienne to become his private secretary. The offer was accepted, and for six years the two lived on the most intimate and friendly terms. It was during this period that he accompanied Napoleon to Egypt. In 1802 implication in the disgraceful failure of the army-contractors Coulon caused his dismissal. Three years later, however, he was sent as *chargé d'affaires* to Hamburg. There he was accused of peculation, and was in consequence recalled and compelled to pay one million francs into the public treasury. Bourrienne never forgave this; he became one of Napoleon's bitterest enemies, and after the first abdication

held office for a short time under Talleyrand. In 1815 he was specially excluded from Napoleon's amnesty and fled to Belgium. After the fall of the emperor he sat for some years in the Chamber of Representatives, but his official salary could not support his extravagance, and in 1828 he took refuge from his creditors in Belgium. There he occupied himself in drawing up the *Mémoires* of Napoleon, which were published in 1829 and 1830. The revolution of 1830 and the discomforts of his private life so preyed upon his mind that his reason became unhinged, and he had to be removed to an asylum near Caen, where he died in 1834. Bourrienne's *Mémoires*, 10 vols. 8vo, 1829–31, contain much interesting information regarding Napoleon, but while lively and entertaining, they are in many points to be received with caution. Some of the inaccuracies were pointed out by Boulay de la Meurthe in *Bourrienne et ses erreurs*, 2 vols. 1830.

BOURSAULT, Edmund, a French dramatist and satirist, was born at Muci-l'Eveque, Burgundy, in 1638. On his first arrival in Paris in 1651 his power of language was limited to Burgundian patois, but he soon gained such reputation as an author, that Louis XIV. directed him to draw up a book for the education of the Dauphin. In compliance with this order Boursault produced his *Veritable étude des souverains*, which pleased so greatly the king that he offered to appoint the author tutor to his son, an office which Boursault's ignorance of Latin compelled him to decline. He obtained a considerable pension as editor of a rhyming gazette, which was, however, suppressed for ridiculing a capuchin, and Boursault was only saved from the Bastille by the influence of Condé. Two of his dramas, *Esope à la Ville* and *Esope à la Cour* were highly popular, and Corneille declared his tragedy *Germanicus* to be worthy of Racine. His best comedy was *Mercure Galant*, or *Comedie sans Titre*, as it was afterwards, named. He accused Molière of impiety, and assailed *L'Ecole des Femmes* in *Le Portrait du Peintre*. Molière retaliated by contemptuously referring to him in *L'Impromptu du Versailles*. His *Satyre des Satyres* was directed against Boileau, whom, however, he afterwards generously offered to assist. In return for this kindness Boileau erased Boursault's name from his satires. Boursault died at Montluçon, where he held the office of collector of taxes, September 15, 1701.

and eloquence in the great German series of histories of the sciences from the Renaissance downwards. The first volume of the *Geschichte des neuern Poesie und Beredsamkeit* appeared in 1805, the twelfth and last in 1815. It is a work of great research, and has very substantial merits. It is, however, somewhat unequal, the portions on German and Spanish literature being superior to any of the rest. Part of the extended work has been translated into English as a *History of Spanish Literature*. Bouterwek died in 1828.

BOVALI, Bouali, or Boali, a town of Africa, capital of the kingdom of Loango, situated in 4° 30′ S. lat. and 12° 1′ E. long., on the right bank of a river of the same name not far from the coast. The vicinity is fertile but unhealthy. A large trade is carried on in pepper, dye-woods, ivory, and slaves. Population estimated at 15,000.

BOVES, a township of Italy, in the province of Cuneo in Piedmont, situated at the foot of the Alps, about 4 miles from the city of Cuneo. There are iron-mines and marble quarries in the neighbourhood. Population, 9549.

BOVINO (the ancient *Vebinum* or *Vibonium*), a fortified town of Italy, province of Capitanata, 18 miles S.S.W. of Foggia. It is the seat of a bishopric and of a court of primary jurisdiction, and has a cathedral and several churches and convents. Here the Imperialists defeated the Spaniards in 1734. Population, 7088.

BOW, the weapon of the archer. See Archery, vol. ii. p. 371, and Arms and Armour, p. 553.

BOWDICH, Thomas Edward, an English traveller, born at Bristol in 1790, was brought up by his father for commercial life, and in 1814 obtained an appointment on the western coast of Africa. Two years afterwards, on his return home, he was sent out by the African Company as their agent to the king of the Ashantees. In 1819 he published a quarto volume giving an account of that remarkable people. He then seems to have spent a considerable time at Paris in the study of the natural sciences. During his stay in Europe he edited several works on Africa, and published an excellent pamphlet on the British settlements on the western coast of Africa. He again visited Africa in 1822, with a firm resolution of devoting himself to the exploration of its interior; but he was attacked by fever on the Gambia, and died January 10, 1824. His widow, who had accompanied him, edited several productions of his pen after his death.

BOWDITCH, Nathaniel, a self-taught Amercian mathematician, born in 1773, of humble parents, at Salem in Massachusetts. He was bred to his father's business as a cooper, and afterwards apprenticed to a ship-chandler. His taste for mathematics early developed itself; and he acquired Latin that he might study Newton's *Principia*. In 1795 he sailed as supercargo, in which capacity he made four long voyages; and, being an excellent navigator, he afterwards commanded a vessel, instructing his crews in taking lunar and other observations. He edited three editions of Hamilton Moore's *Navigation*, and in 1802 published a valuable work, *New American Practical Navigator*, founded on the earlier treatise by Moore. In 1804 he became actuary to a Boston insurance company; and in the midst of his active and useful career published a translation of the *Mécanique céleste* of Laplace, with annotations,—a work which will better prove the great acquirements of this self-taught philosopher than any laboured panegyric. He died at Boston in 1838. A life of Bowditch was written by his son in 1839, and is prefixed to the last volume, published posthumously, of the translation of Laplace.

BOWLES, Caroline Anne. See Southey, Caroline.

BOWLES, William Lisle, poet and critic, was born at King's Sutton, of which his father was vicar, in 1762. At

the age of fourteen he was entered on the foundation at Winchester school, the head-master at the time being Dr Joseph Warton. In 1781 he left as captain of the school, and proceeded to Trinity College, Oxford, to a scholarship to which he had been elected. Two years later he gained the chancellor's prize for Latin verse, and soon after left the university, not taking his degree as master till 1792. In 1789 he published, in a small quarto volume, *Fourteen Sonnets*, which met with considerable favour at the time, were hailed with delight by Coleridge and his young contemporaries, and have since been recognized as the first notes of the modern revolt against the artificial school of poetry, the traditions of which had descended from Pope. The *Sonnets* even in form were a revival, a return to the older and purer poetic style, and by their grace of expression, melodious versification, tender tone of feeling, and vivid appreciation of the life and beauty of nature, stood out in strong contrast to the affected common-places which at that time formed the bulk of English poetry. A second edition of the little volume was called for in the same year in which it had appeared, and there have been many subsequent editions. A few short pieces were published in 1790 and 1792, which were also received with favour. After taking his degree at Oxford he entered the church, and was soon appointed to the vicarage of Chicklade in Wiltshire. In 1797 he received the vicarage of Dumbleton in Gloucestershire, and in 1804 was presented to the vicarage of Bremhill in Wiltshire. In the same year he was collated by Bishop Douglas to a prebendal stall in the cathedral of Salisbury. In 1818 he was made chaplain to the Prince Regent, and in 1828 he was elected residentiary canon of Salisbury. He died at Salisbury in April 1850, aged 88. Of the longer poems published by Bowles none attain a very high standard of excellence, though all are distinguished by purity of imagination, cultured and graceful diction, and great tenderness of feeling. The most extensive were *The Spirit of Discovery*, 1804, which was mercilessly ridiculed by Byron; *The Missionary of the Andes*, 1815; *The Grave of the Last Saxon*, 1822; and *St John in Patmos*, 1833. Bowles is perhaps more celebrated as a critic of poetry than as a poet. In 1807 he published an edition of Pope's works with notes and an essay on the poetical character of Pope. In this essay he laid down certain canons as to poetic imagery which, with slight modification, have been since recognized as true and valuable, but which were received at the time with strong opposition by all admirers of Pope and his style. The "Pope and Bowles" controversy brought into sharp contrast the opposing views of poetry, which may be roughly described as the natural and the artificial. Bowles maintained that images drawn from nature are poetically finer than those drawn from art; and that in the highest kinds of poetry the themes or passions handled should be of the general or elemental kind, and not the transient manners of any society. These positions were vigorously assailed by Byron, Campbell, Roscoe, and others of less note, while for a time Bowles was almost solitary. Hazlitt and the Blackwood critics, however, came to his assistance, and on the whole Bowles had reason to congratulate himself on having once for all established certain principles which might serve as the basis of a true method of poetical criticism, and of having inaugurated, both by precept and by example, a new era in English poetry. Among other prose works from his prolific pen was a *Life of Bishop Ken*, 2 vols., 1830-31.

BOWLS, one of the oldest and most popular of English pastimes, the origin of which can be traced back to the 12th century. William Fitzstephens, in his *Survey of London*, written during the last quarter of that century, states that in the summer holidays youths took exercise amongst other pastimes *in jactu lapidum*, "in throwing of stones." This might be taken as referring to throwing stones by slings or other artificial means, were it not that the next pastime mentioned is "slinging of missiles to be delivered beyond a certain mark (*amentatis missilibus ultra metam expediendis*)." Fitzstephens was both an accurate observer and a careful writer, and he clearly alludes to two distinct exercises. In early days stone spheres are known to have been used for bowling, and the like thing and name were in vogue for the next two centuries, in fact till 11 Henry IV. (1409). There is little doubt, therefore, that Fitzstephens here refers to bowls. It has been a matter of speculation whether bowling was first practised in the open air on turf or under cover in alleys, and Fitzstephens may help to decide the question. He states that the citizens went outside the city walls into the suburbs to witness these games, but the alleys were within the walls and in the midst of the population. Again, these alleys were always held up as scenes of vice and debauchery, and it is certain that had they existed at this date they would have been included in the resorts forbidden to the clergy by the constitutions of Walter de Cantilupe, bishop of Worcester, 24 Henry III. (1240). In the Close Roll, 39 Ed. III. (1366) mem. 23, *jactus lapidum*, "throwing of stones," is mentioned as one of the *ludos inhonestos et minus utiles aut valentes*, "games alike dishonourable, useless, and unprofitable." But then there was a reason for this depreciation. The king was concerned lest the practice of archery, so much more important to the military spirit of the kingdom, should suffer, and the same reason prompted the action of Parliament. By 12 Rich. II. cap. 6 (1388), servants, artificers, and labourers were forbidden—amongst other games to play at *gettre de peer*, or "casting of the stone," as the practice of archery was becoming lax. This statute was confirmed by 11 Henry IV. cap. 4. (1409-10), wherein "*gettre de peer*" is again forbidden. From 17 Ed. IV. cap. 3 (1477-8) it appears that bowling still remained in disrepute; for "half-bowl" is included among the "many new imagined plays" which were followed by all classes "to their own impoverishment, and by their ungracious procurement and encouraging do induceen other into such plays till they be utterly undone and impoverished of their goods." Even murders, robberies, and felonies were the consequence. Accordingly, it was enacted that any one playing at half-bowl after the following Eastar, or the occupier or governor of any "house, tenement, garden, or other place," where such games are permitted, should be punished by fines and imprisonment. Here it is probable that both the outdoor and indoor games are referred to, as "house" and "garden" are mentioned, and it may be concluded that by this time alleys had sprung into existence in towns. This then may be considered the first mention of the game as practised under cover, though it is equally clear that alleys had not entirely superseded greens.

punishment was to be inflicted, except binding offenders over by their own recognizances, and making them find sureties not to break the law again. Artificers, servants, and the like, might play during Christmas time in their masters' houses and presence, but no one could at any time "play at any bowle or bowles in open place out of his garden or orchard," whilst a licence might be granted to any one worth over £100 per annum to play privately in his own domain, but not to keep any common or open place of play. By 2 and 3 Mary, cap. 9 (1555), these licences were cancelled, evidently for religious and political reasons, as they were considered excuses for "unlawful assemblies, conventicles, seditions, and conspiracies." The evil still continued and remained irrepressible. Stephen Gosson, in his *School of Abuse* (1579), says—

"Common bowling alleys are privy moths that eat up the credit of many idle citizens; whose gains at home are not able to weigh down their losses abroad; whose shops are so far from maintaining their play, that their wives and children cry out for bread, and go to bed supperless often in the year."

Again, twenty years later, Stow, in his *Survey of London*, states—

"What should I speak of the ancient daily exercises in the long bow by citizens of this city, now almost clean left off and forsaken? I overpass it; for by the means of closing in the common grounds, our archers, for want of room to shoot abroad, creep into bowling alleys and ordinary dining houses nearer home, where they have room enough to hazard their money at unlawful games. And there I leave them to take their pleasure."

Stow also mentions in another place that the gardens of old Northumberland House, in Coleman Street, City,

"Were made into bowling alleys, and other parts into dining houses, common to all comers for their money, there to bowl and hazard; but now, of late, so many bowling alleys and other houses for unlawful gaming have been raised in other parts of the city and suburbs, that this, their ancient and only patron of misrule, is left and forsaken of her gamesters." Again, Goswell Street is described as "replenished with small tenements, cottages, alleys, gardens, banqueting houses, and bowling places."

The law, doubtless, was transgressed with impunity until the beginning of the 18th century, when power was given by 2 George II. cap. 28, § 9 (1728), and confirmed by 18 George II. cap. 34 (1745), to commit offenders to prison. From this date alleys were rigorously suppressed, whilst greens began to increase rapidly; and, during the 18th century, no country gentleman's mansion was considered complete without one. There is evidence that it was a royal game, since Stow states that bowling alleys were amongst the additions made by Henry VIII. to Whitehall, and the unfortunate Charles I. was an enthusiast of the open-air pastime. During his confinement at Holmby, Northamptonshire, he frequently went over to Lord Vaux's at Harrowden, and Earl Spencer's at Althorpe, both of which seats possessed unrivalled bowling greens. He is said to have been engaged at the game when seized by Cornet Joyce. After the suppression of alleys "long bowling," or "Dutch rubbers," was practised for a short time. It consisted of bowling at nine pins, placed on a square frame 30 yards distant, but does not appear ever to have found much favour in England. The first regular bowling club of which there exists any trace is the Willowbank Club founded in Glasgow at the commencement of the 19th century. The game is now chiefly practised in the northern counties of England and in Scotland. In the present era of violent athletic exercises its principal votaries are middle-aged and elderly persons, to whom it affords a pleasant and not too vehement exercise during summer evenings.

For the outdoor pastime the first requisite is a smooth and level plot of turf, well mown, watered, rolled, and kept in order,—hence the comparison, "as smooth as a bowling green." The earliest delineation extant of the game shows two players with a ball each, but no jack or mark to bowl at. It is presumed from this that the first cast his bowl to constitute a mark for the second to play at and knock from its position. Probably it was soon found expedient to introduce some definite mark, and in a 13th century MS., marked 20 Ed. IV., in the Royal Library, there is a picture of a game of bowls being played with a small cone erected at each end. Here the principle was evidently the same as at present, viz., to see who could cast his bowl nearest the mark. The modern green may be laid out on any suitable piece of smooth and level turf. The dimensions vary, according to the ground available, but from 90 to 150 feet in length, with a proportionate width, is found most suitable. The bowls are made of *lignum vitæ*; and, instead of being perfect spheres, are more or less oval with a bias. Formerly bias was accorded them by loading one side with lead, but now the more simple method of turning one-half of the oval smaller or leaner than the other half is universally adopted. The chief difficulty of the game consists in each player's mastering the bias of his own particular bowl. The "jack" or mark to be bowled at consists of a white ball of smaller size, which has superseded the old-fashioned cones. "Pegs" are a length of cord, with one end firmly attached to a bone or wooden peg, and the other passing through a hole in a similar peg. They are used for measuring which of two bowls is nearest the jack; and, if the distance be under a yard, the "standard"—consisting of a light straw or reed —may be called into requisition. A "rub" or "set" is when a jack or bowl, *in transitu*, comes in contact with any object on the green. The "footer" is the small piece of material—cocoa-nut matting is the best—whereon each player stands in delivering his ball. "Cast," or "point," is the term for each unit in scoring the game, which is "up" or won when the number of casts agreed on have been obtained by the winning side. A "dead bowl" is one knocked off the green, or against one lying in the ditch, or an illegally played bowl, and must at once be removed from the green. Should the boundary of the green consist of fencing, touching the fence constitutes a dead bowl. "Mark," or "set a mark," means the delivery of the jack at the commencement of a game. The jack must be bowled at least 63 feet from the footer and not over 3 feet from the edge of the green. The bowling generally takes place alternately from the two "ends" of the green. A "void end" is when neither side can score a cast. "Turning the jack" is when a player claims the game to be finished as the bowls then lie, and can only occur when one side has but a single bowl to deliver, all the opposite side's bowls having been cast. For the rules of the outdoor game as now played, reference may be made to Mitchell's *Manual of Bowl-playing*, Glasgow, 1865.

In France, according to Cotgrave, there formerly existed a game termed *carreau*, somewhat similar to bowls, the jack or mark being set up on a square stone at the end of an alley.

In the United States of America a game of bowls, termed "Ten Pins," is very popular. It is strictly an indoor game, played in alleys 60 feet by 4 feet. Ten wooden pins are set up at the further end of the alley, in the shape of an equilateral triangle with the apex (termed the "king pin)" towards the players. The object is to knock down the greatest number of pins with the fewest balls. These are made of *lignum vitæ*, unlimited in size or weight, but perfect spheres, instead of being biassed. A game consists of ten "rolls" of three balls each (if necessary), or thirty in all. The score is kept on a large vertical slate with ten divisions, corresponding to the ten rolls, for each player. The chief point is to try and hit the king pin at the apex of the triangle, as this affords the best chance of knocking down all the pins. Should a player succeed in doing so with the *first* ball of a roll he

gains a "double spare," his bowling is over for that roll, and he is entitled to add whatever number of pins he knocks down with the first *two* balls of the next roll to the ten already down. Should he gain another double spare with the first ball of the succeeding roll he has to wait for the first ball of a third roll before the total score for the first roll can be ascertained, and so on in succession. Accordingly, should a player obtain a double spare in each roll—or ten in all—his total reaches 300, the highest attainable. If a double spare be scored with the first ball of the tenth roll, the player is entitled to bowl his two remaining balls at once as he has no further rolls to play. Should he knock down all the pins with the first *two* balls of a roll, he gains a "single spare," his bowling is over for that roll, and he is in a similar manner entitled to add whatever number of pins he knocks down with the *first* ball of the next roll to the ten already down. The technical name for this method of scoring is "counting old and new." There are a few ten-pin alleys in London and the suburbs, but the pastime is not much practised in England. The rules will be found in *The Modern Pocket Hoyle*, New York. (H. F. W.)

BOWRING, SIR JOHN, an eminent English linguist, translator, political economist, and miscellaneous writer, was born at Exeter, October 17, 1792. He was a descendant of an old Puritan family; and he became in early life an ardent disciple in the school of utilitarianism and philosophical radicalism, whose prophet was Jeremy Bentham. He did not, however, share his master's contempt for poetry and the belles lettres, but was a diligent student of literature and foreign languages, especially those of Eastern Europe. His attainments as a linguist were of remarkable extent. He stated that he knew two hundred languages and could speak one hundred. This, of course, does not mean more than that he had some slight acquaintance with them; but it is certain that he had a pretty good knowledge of forty, and these were languages of various classes. This gives him a place, with Mezzofanti and Von Gabelentz, among the greatest linguists of the world. The first fruits of his study of foreign literature appeared in *Specimens of the Russian Poets*, published in two volumes in 1821–23. These were speedily followed by *Batavian Anthology* (1824), *Ancient Poetry and Romances of Spain* (1824), *Specimens of the Polish Poets*, and *Servian Popular Poetry*, both in 1827. During this period he began to contribute to the newly-founded *Westminster Review*, of which he was appointed editor in 1825. By his contributions to the *Review* he obtained considerable reputation as political economist and parliamentary reformer. He advocated in its pages the cause of free trade long before it was popularized by the eloquence of Richard Cobden and John Bright. He pleaded earnestly in behalf of parliamentary reform, Catholic emancipation, and popular education. In 1828 he visited Holland, and during his stay there the university of Groningen conferred on him the degree of doctor of laws. In the following year he was in Denmark, occupying himself with preparations for the publication of a collection of Scandinavian poetry. Bowring, who had been the trusted friend of Bentham during his life, was appointed his literary executor, and was charged with the task of preparing a collected edition of his works. This appeared in eleven volumes in the years 1838 and 1839. Meanwhile Bowring had entered Parliament in 1835 as member for Kilmarnock; and in the following year he was appointed head of a Government commission to be sent to France to inquire into the actual state of commerce between the two countries. He was engaged in similar investigations in Switzerland, Italy, Syria, and some of the German States. The results of these missions appeared in a series of reports laid before the House of Commons. After a retirement of four years he sat in Parliament from 1841 till 1849 as member for Bolton. During this busy period he found leisure for literature, and published in 1843 a translation of the *Manuscript of the Queen's Court*, a collection of old Bohemian lyrics, &c. In 1849 he was appointed British consul at Hong-Kong, and superintendent of trade in China, a post which he held for four years. After his return he distinguished himself as an advocate of the decimal system, and published a work entitled, *The Decimal System in Numbers, Coins, and Accounts* (1854). The introduction of the florin as a preparatory step was chiefly due to his efforts. Knighted in 1854, he was again sent the same year to Hong-kong as governor, invested with the supreme military and naval power. It was during his governorship that a dispute broke out with the Chinese; and the irritation caused by his "spirited" or high-handed policy led to the second war with China. In 1855 he visited Siam, and negotiated with the king a treaty of commerce. After the usual five years of service he retired and received a pension. His last employment by the English Government was as a commissioner to Italy in 1861, to report on our commercial relations with the new kingdom. Sir John Bowring subsequently accepted the appointment of minister plenipotentiary and envoy extraordinary from the Hawaiian Government to the courts of Europe, and in this capacity negotiated treaties with Belgium, Holland, Italy, Spain, and Switzerland. In addition to the works already named he published—*Poetry of the Magyars* (1830); *Cheskian Anthology* (1832); *The Kingdom and People of Siam* (1859); a translation of *Peter Schlemihl*; translations from the Hungarian poet, Alexander Petöfi (1866); and various pamphlets. He was elected F.R.S. and F.R.G.S., and received the decorations of several foreign orders of knighthood. Bowring was twice married; his second wife survived him, with several sons, who have attained distinction in various fields. He died at Claremont, near Exeter, November 23, 1872.

BOXWOOD, the wood obtained from the Euphorbiaceous genus *Buxus*, the principal species being the well-known tree or shrub, *B. sempervirens*, the common box, in general use for borders of garden walks, ornamental parterres, &c. The other source of the ordinary boxwood of commerce is *B. balearica*, which yields the variety known as Turkey boxwood. The common box is grown throughout Great Britain, in the southern part of the European continent generally, and it appears to extend through Persia into India, where it is found growing on the slopes of the Western Himalayas. Only a very small proportion of the wood suitable for industrial uses is now obtained in Great Britain. The box is a very slow growing plant, adding not more than 1½ or 2 inches to its diameter in twenty years, and on an average attaining only a height of 16 feet, with a mean diameter of 10½ inches. The leaves of this species are small, oval, leathery in texture, and of a deep glossy green colour. *B. balearica* is a tree of considerable size, attaining to a height of 80 feet, with leaves three

and it is a favourite wood for small carvings. The use of boxwood for turnery and musical instruments is mentioned by Pliny, Virgil, and Ovid. The quantity of the wood which passes out from Constantinople yearly is estimated at from 5000 to 7000 tons, with about 1500 tons more of inferior and small pieces. While the consumption is continually increasing the present sources of supply are rapidly becoming exhausted, the forests near the sea are denuded of their best trees, and access to the wood growing in the interior of the countries around the Black Sea is difficult owing to the want of means of internal communication. The consequent increase of the cost of boxwood has led to frequent attempts to discover other woods which might take its place for the purposes of the wood engraver; but none of the numerous substitutes proposed have hitherto been found to possess the necessary combination of properties.

BOYACA, a village in the state of Boyaca, in the Republic of Colombia, situated about 20 miles south of the capital Tunja, and celebrated as the scene of the victory of Bolivar over the Spaniards in 1819. See Bolivar.

BOYCE, Hector. See Boece, vol. iii. p. 849.

BOYCE, William, an English musical composer of eminence, was born in London in 1710, and died there in 1779. As a chorister in St Paul's he received his early musical education from King and Dr Greene, and he afterwards studied the theory of music under Dr Pepusch. In 1736 he was appointed organist of St Michael's church, Cornhill, and in the same year he became composer to the chapel royal. In 1749 he received the degree of doctor of music from the University of Cambridge, as an acknowledgment of the merit of his setting of the ode performed at the installation of the duke of Newcastle as chancellor. He became master of the king's band in succession to Greene in 1757, and soon afterwards he was appointed principal organist to the chapel royal. As an ecclesiastical composer Boyce ranks among the best representatives of the English school. His two church services and his anthems, of which the best specimens are *By the Waters of Babylon* and *O, Where shall Wisdom be found*, are still frequently performed. Of his other works the best known are the serenade of *Solomon*, a setting of David's lamentation over Jonathan, and twelve trios for two violins and a bass, which were long popular. One of his most valuable services to the art was his publication (1760) of a collection of English church music in three volumes quarto, which included all the best compositions of the two preceding centuries. The collection had been begun by Greene, but it was mainly the work of Boyce.

BOYD, Zachary, a learned clergyman of the Scottish Church, was born towards the end of the 16th century, and died in 1653 or 1654. He was for many years regent in the college of Saumur in France, but returned to his native country in 1621, to escape the persecution of the Protestants. In 1623 he was appointed minister of the Barony church in Glasgow, and held the office of rector of the university in the years 1634, 1635, and 1645. He bequeathed to the university the half of his fortune, a sum amounting to £20,000 Scots, besides his library and MSS. His bust over the gateway within the court commemorates his important benefactions. The number of his published works was considerable, and eighty-six of his MSS. are said to be preserved in the library of Glasgow College. His poetical compositions are not without some merit, though the remarkable eccentricity of some of them has generally made them a source of amusement rather than edification. The common statement that he made the printing of his metrical version of the Bible a condition of the reception of his grant to the university is a mistake.

His best known works are *The Last Battle of the Soule in Death*, 1629, of which a new edition, with a biography by Mr Neil, was published at Glasgow in 1831; *Zion's Flowers*, 1644; the *English Academie*; and *Songs of Zion*.

BOYDELL, John, an engraver, chiefly known by his plates illustrating Shakespeare, was born at Dorrington in 1719. At the age of twenty-one he came to London and was apprenticed for seven years to an engraver. In 1746 he published a volume of views in England and Wales, and started in business as a printseller. By his good taste and liberality he managed to secure the services of the best artists, and his engravings were executed with such skill that his business became extensive and lucrative. He succeeded in his plan of a Shakespeare gallery, and obtained the assistance of the most eminent painters of the day, whose contributions were exhibited publicly for many years. The engravings from these paintings form a splendid companion volume to his large edition of Shakespeare's works. Towards the close of his life Boydell sustained severe losses through the French Revolution, and was compelled to dispose of his Shakespeare gallery by lottery. It had been his wish and intention to bequeath it to the nation. He died in 1804 before the lottery took place. Some years before his death he had held the position of Lord Mayor of London.

BOYER, Abel, a well-known lexicographer and historian, was born at Castres in France in 1664. Upon the revocation of the Edict of Nantes he first went to Geneva, and then to Franeker, where he finished his studies. Finally he came to England, where he soon acquired such a proficiency in the English language, that he became an author of considerable note, and was employed in writing several periodical and political works. He had for many years the principal management of a newspaper called the *Postboy*, and he likewise published a monthly work entitled *The Political State of Great Britain*. He died at Chelsea in 1729.

He wrote—*Life of Queen Anne*, folio; *History of William III.*, 3 vols. 8vo; *Annals of the Reign of Queen Anne*, 11 vols. 8vo; his best known work is the *Dictionary and Grammar of the French Language*.

BOYER, Alexis, a distinguished French surgeon, was born on the 1st of March 1757, at Uzerches in Limousin. His father was in the humble station of a tailor, and the son received the elements of a medical education in the shop of a barber-surgeon in a provincial town. His evident talent induced his friends to procure his removal to Paris, where he had the good fortune to attract the notice of his two distinguished masters, Louis and Dessault; and his unwearied perseverance, his anatomical skill, and finally his dexterity as an operator, became so conspicuous, that at the age of thirty-seven he obtained the appointment of second surgeon to the Hôtel Dieu of Paris, and was elected professor of operative surgery in the École de Santé. This latter appointment he soon exchanged for the chair of clinical surgery,—a department in which his manual dexterity and his admirable lectures on surgical subjects gained him the highest reputation, and introduced him to extensive practice. Perhaps no French surgeon of his time thought or wrote with greater clearness and good sense than Boyer; and while his natural modesty made him distrustful of innovation, and somewhat tenacious of established modes of treatment, he was as judicious in his diagnosis, as cool and skilful in manipulating, as he was cautious in forming his judgment on individual cases. In 1805 Napoleon nominated him imperial family surgeon, and, after the brilliant campaigns of 1806–7, conferred on him the legion of honour, with the title of Baron of the Empire, and a salary of 25,000 francs. On the fall of Napoleon the merits of Boyer secured him the favour of the succeeding sovereigns of France, and he was consulting-surgeon to Louis XVIII., Charles X., and Louis Philippe.

In 1835 he succeeded Deschamps as surgeon-in-chief to the Hôpital de la Charité, and was chosen a member of the Royal Academy of Sciences of the Institute of France. From the period of his wife's death, which he took much to heart, his health declined, and he died November 23, 1833, at the age of seventy-six.

His two great works are—*Traité complet de l'anatomie*, in 4 vols. 8vo, 1797–99, of which a fourth edition appeared in 1815, and *Traité des maladies chirurgicales et des operations qui leur conviennent*, 11 vols. 8vo, 1814–26. Of this work a new edition (the 5th), with additions by M. Ph. Boyer, in 7 vols., was published in 1844–53.

BOYER, Jean Baptiste, an eminent French physician, born at Marseilles in 1693. He devoted a long life to the special investigation and treatment of contagious epidemics, with a courage and success which have rarely been surpassed. On the last appearance of the plague in western Europe in 1720, he was one of the physicians sent from Paris by the Government to succour the inhabitants of his native city, then visited by this great calamity. The fearless zeal and ability which he displayed on that occasion procured him a pension and the title of physician in ordinary to the king. Much of his subsequent life was spent in similar expeditions, devoted to philanthropy, wherever pestilential epidemics prevailed; and the value of the services of Boyer were fully acknowledged at Paris, Trèves, Beauvais, Montagne, Brest, and at several places in the Spanish peninsula. He died in 1768.

His best known writings are—*Account of the Plague at Marseilles in 1720*, and *Observations on the Epidemic that prevailed at Beauvais*, Paris, 1750.

BOYER, Jean Piérre, a mulatto general, and for some time the President of Hayti, was born at Port-au-Prince in 1776. He joined the negroes in their war of independence, but after the secession of Toussaint l'Ouverture with his party, was compelled to retire to France. He was well received by Napoleon, and obtained a commission in Leclerc's expedition. After the death of Dessalines, the king of Hayti, Boyer joined Pétion in proclaiming a republic and resisting Christophe, Dessalines's successor. He gallantly and successfully defended Port-au-Prince against the negro troops of Christophe, and on the death of Pétion was named president of the Haytian republic. Two years later the death of Christophe removed his only rival, and he gained almost undisputed possession of the whole island. Absolute power, however, produced its usual effects; Boyer became arbitrary, capricious, and cruel. In 1825 the French compelled the Haytian senate to acknowledge their supremacy, and to guarantee a payment of 150 millions of francs in return for certain liberties granted. The weight of this enormous debt excited the greatest discontent in Hayti. Boyer was able to carry on his government for some years longer, but in 1842 a violent insurrection overthrew his power, and compelled him to take refuge in Jamaica. He resided there till 1848, when he removed to Paris, where he died in 1850.

BOYLE, Charles, earl of Orrery in Ireland, and baron of Marston, in the county of Somerset, the second son of Roger second earl of Orrery, was born at Chelsea in 1676. He was educated at Christ Church, Oxford, and soon distinguished himself by his learning and abilities. Like the first earl of Orrery, he was an author, soldier, and statesman. He translated Plutarch's life of Lysander, and published an edition of the epistles of Phalaris, which engaged him in the famous controversy with Bentley. See Atterbury and Bentley. He was three times member for the town of Huntingdon; and on the death of his brother, Lionel, earl of Orrery, in 1703, he succeeded to that title. He entered the army, and in 1709 was raised to the rank of major-general, and sworn one of her Majesty's privy council. At the battle of the Wood he acted with di[illegible]ed bravery. He was appointed queen's envoy to the states of Brabant and Flanders; and having discharged this trust with ability, he was created an English peer, as Baron of Marston, in Somersetshire. He received several additional honours in the reign of George I, but having had the misfortune to fall under the suspicion of the Gover[illegible] he was committed to the Tower, where he remained six months, and was then admitted to bail. On a subsequent inquiry it was found impossible to criminate him, and he was discharged. He died, after a slight illness, on the 28th of August 1731. Among the works of Roger, earl of Orrery, will be found a comedy, entitled *As you find it*, written by Charles Boyle. The orrery, an astronomical instrument, invented, or at least constructed, by Graham, was named after the earl, who used to amuse his leisure hours with mechanical toys.

BOYLE, John, earl of Cork and Orrery, a nobleman distinguished for his literary attainments, was the only son of the subject of last notice, and was born January 2, 1707. He was educated at Christ Church College, Oxford, and was led by indifferent health and many untoward accidents to cultivate in retirement his talents for literature and poetry. His works are neither numerous nor remarkable. His translation of the *Letters of Pliny the Younger*, with various notes, for the use of his eldest son, was published in 1751, 2 vols. 4to. He also published a *Life of Swift*, in several letters addressed to his second son, and *Memoirs of Robert Carey, Earl of Monmouth*, from a manuscript presented to him by a relation. He died November 16, 1762. His letters from Italy did not appear until 1774, when they were edited, with his life prefixed, by the Rev. J. Duncombe.

BOYLE, Richard, one of the greatest statesmen of the 17th century, generally styled the Great Earl of Cork, was the youngest son of Roger Boyle, and was born at Canterbury, October 3, 1566. He studied at Benet College, Cambridge, and afterwards became a student in the Middle Temple. Having lost his parents, and being unable to support himself in the prosecution of his studies, he became clerk to Sir Richard Manwood, chief baron of the exchequer; but finding this employment little likely to improve his fortune, he went to Ireland. He was then about twenty-two years of age, graceful in person, and possessing many accomplishments, which enabled him to render himself useful to some of the principal persons employed in the Government. In 1595 he married one of the daughters and co-heiresses of William Apsley. This lady died four years afterwards, leaving him a landed estate of £500 a year. He purchased land extensively, and was looked upon with great jealousy by some of the neighbouring proprietors, who did all they could to blacken his character. But he was fortunate enough to find a patron in Queen Elizabeth, and his fortunes, which had been broken by the Munster rebellion, rapidly improved. In consequence of various services and the great ability he
[illegible]

command of his four sons, he defended the province of Munster, and took several strong castles. During this time he paid his forces regularly; and when all his money was exhausted, he converted his plate into coin. He died on the 15th September 1644.

BOYLE, Richard, earl of Burlington and Cork, son of the subject of last notice, was born in 1612. He greatly distinguished himself by his loyalty to Charles I., whom during his troubles he supplied with both money and troops; but at last he was obliged to compound for his estate. He contributed all in his power to the Restoration, and by Charles II. was created earl of Burlington (Bridlington) in 1663. He died in January 1697–8, aged eighty-six.

BOYLE, Robert, one of the greatest natural philosophers of his age, and one of the founders of the Royal Society of London, was the seventh son and fourteenth child of Richard Boyle, earl of Cork, and was born at Lismore Castle in the province of Munster, Ireland, January 25, 1627. In his earliest years he learnt to speak Latin and French, and he was only eight years old when he was sent to Eton, his father's friend, Sir Henry Wotton, being then provost of the college. Here he studied about three years, and was next placed as private pupil with the rector of Stalbridge in Dorsetshire, where his father had just taken up his residence. In 1638 after a visit to London he travelled in France accompanied by a French tutor, and studied above a year at Geneva. In the autumn of 1641 he visited Switzerland and Italy, spending the winter of 1641–42 at Florence. Here he studied the works of Galileo, who died near Florence the same winter. On reaching England in 1644 he learnt the death of his father, who had left to him the manor of Stalbridge and estates in Ireland. It was in the following year that he became a member of a society of scientific men, who in consequence of the political agitation of the times used to hold their meetings with as much privacy as possible, first in London and afterwards at Oxford; this became subsequently famous as the Royal Society. In 1646 he settled at Stalbridge, and from that time his whole life was devoted to study, scientific research and experiments, and authorship. After making several visits to his estates in Ireland he took up his abode at Oxford in 1654, and there enjoyed the society of many learned men. He resided at Oxford for fourteen years; and it was during this period that he made important improvements in the air-pump, and by a long series of experiments with it made various discoveries on the properties of air, the propagation of sound, &c., which are recorded in his voluminous writings. Boyle was at the same time an ardent student of theology, and numbered among his friends the eminent Orientalists Pococke, Hyde, and Clarke, and Dr Thomas Barlow, Bodleian librarian and bishop of Lincoln. At the Restoration he was favourably received at court, and was advised to enter the church; but this he declined to do, alleging that it was not his vocation, and that he believed his writings on religious subjects would have greater weight coming from a layman than from a paid minister of the church. His anxiety to promote the spread of Christianity appeared in various munificent acts. He bore the expense of preparing a Malay translation of the Gospels and the Acts of the Apostles, and of an Irish version of the Bible. He contributed largely to the cost of the Welsh Bible and of a Turkish New Testament, and gave a large sum to the translator of the work of Grotius *De Veritate* into Arabic. He supported liberally the projects for spreading the Gospel in India and in America, and gave away annually a large sum for charitable purposes. He made his first appearance as author in 1660, by the publication at Oxford of a volume entitled *New Experiments, Physico-Mechanical, touching the Spring of Air and its Effects*, and of a devotional work entitled *Seraphic Love, or some Motives and Incentives to the Love of God.*

When the Royal Society was incorporated (1663) Boyle was named a member of the council. He communicated many important memoirs to the *Philosophical Transactions*, and, in 1680, was elected president of the society, but from a scruple about oaths he declined this honour. Boyle was at one time deeply interested in alchemy, and carried on experiments on the transmutation of metals, in which Newton also took much interest. It was through his efforts that the statute of Henry IV. cap. 4, against the multiplying of gold and silver was repealed in 1689. After leaving Oxford in 1668 he settled in London; and here he spent the rest of his days, residing in the house of his sister Lady Ranelagh. He was never married. In person he was tall, slender, and of a pale countenance. His constitution was far from robust, and throughout his life he suffered from feeble health and low spirits. While his scientific discoveries procured him wide and lasting renown, his private character and virtues, the charm of his social manners, his wit and conversation, endeared him to a large number of personal friends. As a man of science he was ranked by his contemporaries among the greatest; and although some abatement of this very high estimate has since been admitted, he still holds a place of distinction as the first great investigator who carried out in his labours the principles of the *Novum Organum*. So earnest was his devotion to Bacon that for many years he could not be persuaded to read the works of Descartes, lest he should be tempted out of his chosen path. His strength lay in the patient research and observation of facts. He did not display that power of divination of their meaning and, of detection of their relations which is the characteristic of genius. His desire was to contribute by his researches, in the true spirit of the Baconian philosophy, to the service of man's life; and in this he had a large measure of success. The same practical aim is apparent in his theological writings. He was no controversialist, and does not appear to have taken much, if any interest in the great political and religious movements of his day. About 1690 his health began seriously to fail, and he was obliged gradually to withdraw from his public engagements. He discontinued the communication of memoirs of new discoveries to the Royal Society, resigned the post which he had long held of governor of the corporation for propagating the Gospel in New England, and announced by public advertisement his intention no longer to receive visits. The "retired leisure" which he thus secured was devoted to important chemical investigations, the account of which he left "as a kind of hermetic legacy to the studious disciples of that art." His health became worse in 1691. On the 23d of December of this year his sister, Lady Ranelagh, with whom he had lived for more than twenty years, died; and a week later, December 30, Boyle died himself. His remains were interred in the churchyard of St Martin's in the Fields, and his funeral sermon was preached by his friend Dr Burnet, bishop of Salisbury, author of the *History of the Reformation*. By his will he founded and endowed the "Boyle Lectures," the purpose of which is the demonstration of the truth of the Christian religion against atheists, theists, pagans, Jews, and Mahometans.

It is unnecessary to do more than enumerate the more important publications of this laborious investigator. His first work has already been mentioned. It was followed, in 1662, by *The Sceptical Chemist*, subsequently reprinted with additions. His *Considerations touching the Usefulness of Experimental Natural Philosophy* appeared in 1663, and was followed by a second part in 1671. His *Experiments and Considerations upon colours, with Observations on a Diamond that Shines in the Dark*, also appeared in 1663—a treatise which broke ground on a theme afterwards more profoundly treated by Newton.

His next scientific work was entitled, *New Experiments and Observations upon Cold* (1665). This was followed by the *Origin of Forms and Qualities according to the Corpuscular Philosophy* (1666); a continuation of his first work on the air (1669); *Tracts about the Cosmical Qualities of things, the Temperature of the Subterraneous Regions, and the Bottom of the Sea* (1669), a volume which gave rise to much discussion, its statements being founded on experiment; *Origin and Virtues of Gems* (1672); *Essays on the Subtilty and Determinate Nature of Effluvia* (1673); tracts on the *Saltness of the Sea*, the *Moisture of the Air*, the *Natural and Preternatural State of Bodies, Cold, Hidden Qualities of the Air, Celestial Magnets, Hobbes's Problem of a Vacuum*, and the *Cause of Attraction and Suction* (1674); *Experiments and Notes about the Mechanical Origin or Production of Particular Qualities*, including a discourse on electricity (1676); the *Aerial Noctiluca, or some new Phenomena, and a Process of a Factitious Self-shining Substance* (1680); *New Experiments and Observations upon the Icy Noctiluca, to which is added a Chemical Paradox* (1682); a further continuation of his first work on the air (1682); *Memoirs for the History of Human Blood* (1684); *Short Memoirs for the Natural Experimental History of Mineral Waters* (1685); *Medicina Hydrostatica* (1690); and *Experimenta et Observationes Physicæ* (1691). Of his religious and theological writings we may mention, *An Essay on Scripture*, of which one portion was published in 1663, and the whole at a later date by his friend Sir Peter Pett; *Occasional Reflections upon several Subjects* (1665), a strange medley of trivialities and grave thoughts, amusing, yet not wholly unwise, which was assailed and ridiculed by Dean Swift in *A Pious Meditation upon a Broomstick, in the Style of the Honourable Mr Boyle*, and by Butler in *An Occasional Reflection on Dr Charlton's feeling a Dog's Pulse at Gresham College* (a neat reprint of the *Occasional Reflections* was published at Oxford in 1848); *The Excellency of Theology, compared with Philosophy*, written in the year of the Great Plague, but not published till 1673; *Considerations about the Reconcilableness of Reason and Religion, with a Discourse about the Possibility of the Resurrection* (1655); *A Discourse of Things above Reason, inquiring whether a Philosopher should admit any such* (1681); a tract on the *High Veneration Man's Intellect owes to God* (1685); *A Free Inquiry into the vulgarly received notion of Nature* (1686); and *The Christian Virtuoso* (1690). Several other works appeared after his death, and among these were—*The General History of the Air designed and begun*; an account of his making the phosphorus, September 30, 1680; and *Medicinal Experiments*. An incomplete edition of Boyle's works appeared at Geneva some years before his death. A useful classified abridgment was published by Dr Peter Shaw, editor of an abridgment of Bacon's Philosophical Works. The first complete edition was that of Dr Birch, which appeared, with a Life of the author, in 5 vols. folio, in 1744. Another complete edition was issued in 6 vols. 4to, in 1772. A portrait of Boyle, by Kerseboom, which is in the possession of the Royal Society, formed part of the National Portrait Exhibition at South Kensington in 1866. Boyle bequeathed his natural history collections to the Royal Society.

BOYLE, ROGER, earl of Orrery, fifth son of the Great Earl of Cork, was born in April 1621, and was made Baron Broghill when only five years old. He distinguished himself while a student at Dublin College, and afterwards made the tour of France and Italy. Soon after his return he married Margaret Howard, sister to the earl of Suffolk; and passing over to Ireland with his bride he found the country in a state of rebellion, and assisted his father in opposing the insurgents. Upon the execution of the king, he retired to his seat at Marston in Somersetshire; but his spirit could ill brook this state of inactivity, and he therefore resolved to cross the seas, and apply to Charles II. for a commission to raise forces to restore the monarchy and recover his own estate. Under the pretence of visiting Spa for his health, he proceeded as far as London, where he received a message from Cromwell, then general of the parliamentary forces and a member of the committee of state, intimating his intention to wait upon him. During the interview Cromwell told him that the committee were apprised of his design: and when Broghill assured him that the intelligence was false, Cromwell produced copies of several of his confidential letters, which reduced him to the necessity of asking Cromwell's pardon, and requesting his advice in such a conjuncture. Cromwell told him, that though he had hitherto been a stranger to his person, he was not so to his merit and character; that he had heard how gallantly he had behaved in the Irish wars; and he concluded by offering him a command as general officer, exempt from all oaths and engagements,—adding that he should not be obliged to draw his sword against any but the Irish rebels. Lord Broghill, greatly surprised at so unexpected an offer, requested some time for deliberation. But Cromwell brusquely told him that he must determine instantly, that he himself was about to return to the committee, who were still sitting, and that if he rejected their offer, they had determined to send him to the Tower. Broghill, finding that his liberty and life were in the utmost danger, pledged his honour that he would faithfully serve against the Irish rebels; and accordingly, by Cromwell's instructions, he passed over into Ireland, where by many important services he fully justified the opinion which had been formed of him. A troop of horse which he had raised was soon increased to a regiment of 1500 men, and these he led into the field against the rebels. He was speedily joined by Cromwell, who placed the highest confidence in his new ally, and found him of the greatest value to the interests of the commonwealth.

When Cromwell became Protector, Lord Broghill was made one of his privy council, and admitted to great intimacy and confidence. He continued for some time to assist Richard Cromwell with his counsels, till, seeing that the weak nature of that amiable man would infallibly bring on his fall, he deemed it imprudent still to cling to one whom he could not save, and accordingly retired to his command in Ireland, where affairs shortly after took a turn extremely favourable to the design of the king's restoration. Lord Broghill was not a little instrumental in bringing about that event; and, in consideration of his eminent services, Charles created him earl of Orrery, September 5, 1660. He was soon after made one of the lords justices of Ireland; and his conduct, whilst at the head of affairs in that kingdom, was such as to add greatly to the general esteem in which his character was previously held.

His active and toilsome course of life at length brought on disease and infirmity; but, notwithstanding, he went over to England in 1665, at the king's desire, and mediated with success in a serious misunderstanding which existed between Charles and the duke of York.

On his return Lord Orrery, by his prudent and skilful measures, rendered abortive the scheme of a descent upon Ireland by the Dutch and French, planned by the duke de Beaufort, admiral of France.

About this time a quarrel with his old friend the duke of Ormond, arising from mutual jealousies, became so serious that the disputants resorted to England to defend their respective interests. This quarrel, though of a private beginning, became at last of a public nature. Lord Orrery was impeached, but defended himself so well that the prosecution failed. He lost, however, his public employments; but, retaining the king's favour, he still came frequently to court, and was often consulted on affairs of i

its mouth. About a mile west of Drogheda, an obelisk, 150 feet in height, marks the spot where the forces of William III. gained the celebrated victory over those of James II., on 1st July 1690, known as the "battle of the Boyne."

BOYSE, or Bois, John, one of the translators of the English Bible, was born in Suffolk in 1560. He was educated by his father, the rector of West Stowe, and at an early age exhibited great intellectual powers, being able to read Hebrew when only five years old. He completed his studies at Cambridge, particularly devoted himself to Greek, and for ten years was lecturer on that language in St John's College. At the age of thirty-six he married, and became rector of Boxworth, in Cambridgeshire. He was selected as one of the translators of the Bible, and is said to have completed not only his own share, the Apocrypha, but that of another clergyman. He received a prebendal stall in Ely cathedral from Bishop Andrews in 1615, but had no other preferment. He died in 1643, leaving behind him an immense mass of MSS.

BOZRAH. There are, according to the more usual opinion, two places of this name mentioned in Scripture, one a city of Edom, and the other a city of Moab. About the identification of these cities there has been much discussion, some maintaining that the former occupied the site of the modern village of el-Buseirah, about 25 miles S.E. of the Dead Sea, and that the latter was the city afterward known to the Romans as Bostra and at present as Busrah; while others suppose that the various passages of the Scriptures all refer to one place, and others again that there are two places, but that neither of them is to be identified with Bostra. The first view seems to be freer from difficulties than the other two. Bozrah, or el-Buseirah, is now a small village with a strong fortress on the top of a hill. It is the centre of a pastoral district, and its inhabitants, who number between 100 and 200, are all shepherds. Bozrah, Buzrah, or Bostra, on the other hand, is a very extensive collection of ruins of various ages, situated about 80 miles S. of Damascus. The area within the walls is about a mile and a quarter in length, and nearly a mile in breadth, while extensive suburbs lie without, to the east, north, and west. The principal buildings that can still be distinguished are a temple, an aqueduct, a large theatre (enclosed by a castle of much more recent workmanship), several baths, a triumphal and other arches, three mosques, and what are known as the church and convent of the monk Boheira. In 105 A.D., the city was beautified and perhaps restored from ruin by Trajan, who made it the capital of the province of Arabia. In the reign of Alexander Severus it was made a colony, and in 245 a native of the place, Philippus, ascended the imperial throne. By the time of Constantine it seems to have been Christianized, and not long after it was the see of an extensive bishopric. It was one of the first cities of Syria that was subjected to the Mahometans, and it successfully resisted all the attempts of the Crusaders to wrest it from their hands. As late as the 14th century it was a populous city. (See Burckhardt's *Travels*, Robinson's *Biblical Researches*, Porter's *Damascus*, Freshfield's *Caucasus*.)

BOZZARIS, Marcos, a Greek patriot, was born in Suli towards the close of the 18th century. With the remnant of the Suliotes he crossed in 1803 to the Ionian islands, and in 1820, with some 800 of his countrymen, joined the sultan against Ali Pasha. They soon, however, came over to Ali's party, and fought gallantly against their old enemies the Turks. After the death of Ali the Suliotes carried on the war with great success, and in 1822 were joined by a body of regular troops under Prince Mavrocordato. At the battle of Petta the Greeks were betrayed and defeated with heavy loss. Bozzaris fell back to Missolonghi, which he successfully defended until the arrival of a Hydriote fleet compelled the besiegers to retire. In the summer of 1823 he learned that a large Turkish force had again been despatched against the town, and resolving to anticipate the attack, he set out secretly with 1200 men. On the 20th of August he came upon the encampment of the Turkish vanguard, and a night attack was crowned with success. The victory of the Suliotes was saddened by the loss of Bozzaris, who fell while leading on his men. The assault on the Turkish camp has been made the subject of a very fine poem by Fitz-Greene Halleck.

BRA, a town of Italy in the province of Cuneo and district of Alba, on the River Stura, 25 miles N.E. of Cuneo. It has three parish churches, a gymnasium, a hospital, manufactures of silk and linen goods, and a considerable trade in corn, cattle, wine, and silk. Population, 12,946.

BRABANT, an extensive district in the Netherlands, which formerly constituted a separate duchy, but is now divided between Belgium and Holland. The Belgian portion includes the provinces of Brabant and Antwerp, while the whole of the Dutch portion is still known by its ancient name. Godfrey the Bearded, count of Louvain, who lived in the beginning of the 12th century, was the first to assume the title of count of Brabant, which his great-grandson, Henry I. the Warrior (1190–1235) exchanged for that of duke. The duchy passed in regular succession to Henry II. the Magnanimous (1235–1248), and Henry III. the Debonnair (d. 1261); but on the death of the latter the natural heir was supplanted by his younger brother John I. the Victorious, who added the district of Limburg to his possessions by the battle of Woeringen in 1288, in which he killed his competitor Henry of Luxembourg with his own hand. The next duke, John II., is memorable for the privileges he bestowed on his subjects by the statute of the Common Weal and the charter of Cortemberg. His successor, John III. the Triumphant, had to contend against a rebellion of Brussels and Louvain, and an offensive alliance of his neighbours, but managed to make himself not only secure but formidable. His three sons having died before him without issue, he was succeeded by his daughter, who had married Wenceslas of Luxembourg. The count of Flanders laid claim to the duchy, and, after a considerable struggle, was only bought off by the surrender of Antwerp. In 1404 the whole of Brabant was handed over to the countess of Flanders, and in 1406 her son took the title of duke. On his death at the battle of Agincourt, in which he fought on the side of the French, he was succeeded by John IV., whose marriage and divorce created much excitement in his day. In 1430, on the decease of Philip, second son of John IV., the duke of Burgundy, Philip the Good, was also recognized as duke of Brabant; and in 1440 the country passed to the house of Austria by the marriage of Mary of Burgundy his granddaughter to Maximilian the emperor, who transmitted it to Charles V. and thus to the crown of Spain. In 1648 the northern portion of the duchy succeeded in freeing itself from the Spanish tyranny, while southern Brabant continued under the yoke till 1714. Brabant possessed a liberal constitution known as the *Joyeuse Entrée, Blyde Inkomst*, or Joyous Entrance, which, *inter alia*, prevented the duke from raising the clergy above the other states of the realm, from prosecuting his subjects except in the regular courts, and from appointing foreigners to political office. A consent of the three states—the clergy, the nobles, and the representatives of the chief cities—was necessary for the passing of a law; and the towns had the right of refusing assistance

in any military expedition with the object of which they had not been previously made acquainted. The states usually met every two years, and a permanent committee of the three orders held its session in Brussels. The Brabantine court, under the native dynasty, was famous for the encouragement which it afforded to learning and literature; and more than one of the dukes have left proof of personal culture in the shape of songs. (See Dinaux, *Trouvères Brabançons, Hainuyers*, &c., 1863.)

BRABANT, NORTH, the modern Dutch province, has an area of 231 square miles, and in 1870 the population was 4,832,612. The surface is flat and the soil alluvial. The principal rivers are the Maas, the Aa, and the Dommel. The capital is 's Hertogenbosch, a city of 24,395 inhabitants, and the other chief towns are Breda (14,721), Bergen-op-Zoom (8352), Helmond (5301), and Tilburg (5262).

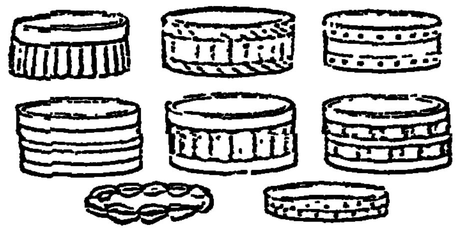
BRABANT, SOUTH, the modern Belgian province, has an area of 1262 square miles, and in 1870 the population was 879,814. Its general features are much the same as those of the Dutch province, though the surface is rather more varied in its elevation. The principal rivers are the Senne, the Dyle, and the Demer. The capital is Brussels with 177,954 inhabitants; and the other cities of importance are Louvain (32,976), Tirlemont (12,354), Nivelles (8800), Diest (7561), and Vilvorde (6844).

BRACCIOLINI, FRANCESCO, an Italian poet, born at Pistoia, of a noble family, in 1566. On his removing to Florence he was admitted into the academy there, and devoted himself to literature. At Rome he entered the service of Cardinal Maffeo Barberini, with whom he afterwards went to France. After the death of Clement VIII. he returned to his own country; and when his patron Barberini was elected pope, under the name of Urban VIII., Bracciolini repaired to Rome, and was made secretary to the Pope's brother, Cardinal Antonio. He had also the honour conferred on him of taking a surname from the arms of the Barberini family, which were bees; whence he was afterwards known by the name of *Bracciolini dell' Api*. During Urban's pontificate the poet lived at Rome in considerable reputation, though at the same time he was censured for his sordid avarice. On the death of the pontiff he returned to Pistoia, where he died in 1645. There is scarcely any species of poetry, epic, dramatic, pastoral, lyric, or burlesque, which Bracciolini did not attempt; but he is principally noted for his mock-heroic poem *Lo Scherno degli Dei*, published in 1618, similar but confessedly inferior to the contemporary work of Tassoni, *Secchia Rapita*. Of his serious heroic poems the most celebrated is *La Croce Racquistata*.

BRACCIOLINI, POGGIO. See POGGIO.

BRACELET, or ARMLET, a personal ornament, made of different materials, according to the fashion of the age and the rank of the wearer. The word is the French *bracelet*, which Ménage derives from *bracelletum*, a diminutive of *bracile*, all formed from the Latin *brachium*, the arm, on which it was usually worn. By the Romans it was called *armilla, brachiale, ocabus*; and in the Middle Ages *boga, bauga, armispatha*.

In the Bible there are three different words which the authorized version renders by "bracelet." These are—1. אצעדה *etsadah*, which occurs in Num. xxxi. 50, 2 Sam. i. 10, and which being used with reference to men only, may be taken to be the *armlet*; 2. צמיד *tsamid*, which is found in Gen. xxiv. 22, Num. xxxi. 50, Ezek. xvi. 11;—where these two words occur together (as in Num. xxxi. 50) the first is rendered by "chain," and the second by "bracelet:" 3. שרות *sheroth*, which occurs only in Isa. iii. 19. The first probably meant armlets worn by men: the second, bracelets worn by women and sometimes by men; and the third, a peculiar bracelet of chain-work worn only by women. In 2 Sam. i. 10, the first word denotes the royal ornament which the Amalekite took



Bracelets.

from the arm of the dead Saul, and brought with the other regalia to David. There is little question that this was such a distinguishing band of jewelled metal as we still find worn as a mark of royalty from the Tigris to the Ganges. The Egyptian kings are represented with armlets, which were also worn by the Egyptian women. These, however, are not jewelled, but of plain or enamelled metal, as was in all likelihood the case among the Hebrews. In modern times the most celebrated armlets are those which form part of the regalia of the Persian kings, and which formerly belonged to the Mongol emperors of India. These ornaments are of dazzling splendour, and the jewels in them are of such large size and immense value that the pair are reckoned to be worth a million of our money. The principal stone of the right armlet is famous in the East under the name of the *Deriâ-e-nur*, or "Sea of light." It weighs 186 carats, and is considered the diamond of finest lustre in the world. The principal jewel of the left armlet, although of somewhat inferior size (146 carats) and value, is renowned as the *Tâj-e-mah*, "Crown of the moon." The imperial armlets, generally set with jewels, may also be observed in most of the portraits of the Indian emperors.

Bracelets have at all times been much in use among barbaric nations, and the women frequently wear several on the same arm. The finer kinds are of mother of pearl, fine gold, or silver; others of less value are made of plated steel, horn, brass, copper, beads, &c.

This species of personal ornament was exceedingly common in Europe in prehistoric times. The bracelets of the Bronze Age were either of gold or bronze, silver being then unknown. In shape they were oval and penannular with expanding or trumpet-shaped ends, having an opening between them of about half an inch to enable them to be easily slipped over the wrist. Those of gold were generally plain, hammered rods, bent to the requisite shape, but those of bronze were often chased with elegant designs showing a cultivated taste. Some forms of spiral armlets of bronze, peculiar to Germany and Scandinavia, covered the whole fore-arm, and were doubtless intended as much for defence against a sword-stroke as for ornament. The

THE BRACHIOPODA constitute an important and well-defined class of Invertebrates, but the exact position the group should occupy in that division of the animal kingdom is still a matter upon which anatomists have not entirely agreed. For many years the species composing the class were referred to the genus *Anomia* of the Lamellibranchiata, but, as was judiciously observed by Edward Forbes, "a close examination shows that there is no relationship between them, but only a resemblance through formal analogy." Milne-Edwards separated the Mollusca into two great divisions, Mollusca and Molluscoida, and in the last he placed the Brachiopoda, Polyzoa, and Tunicata, an arrangement that has been followed by many naturalists. Although the greater number of zoologists have admitted the close connection existing between the Polyzoa and Brachiopoda, considerable doubt has been expressed with respect to the affinities and position of the latter in relation to the Tunicata; moreover, a strenuous effort has been made within the last few years by Steenstrup, Morse, Kowalevsky, A. Agassiz, and others, to demonstrate that the affinities of the Brachiopoda and Polyzoa are with the Worms, and that they should form classes of Annulosa, and be placed close to the Annelids.

According to Agassiz, the transition between such types as Pedicellina to Membranipora and other incrusting Polyzoa is readily explained from the embryology of *Thecidium*, and, in fact, all incrusting Polyzoa are only communities of Brachiopods, the valves of which are continuous and soldered together, the flat valve forming a united floor, while the convex valve does not cover the ventral one, but leaves an opening more or less ornamented for the extension of the lophore. Both Gratiolet and Hancock have expressed the opinion that the Tunicata are in no way related to the Brachiopoda, and that we cannot place these last and the Polyzoa along with the Tunicata in the same division. Gratiolet and some others have considered the Brachiopoda to be allied to the Crustacea, while even the asteridian affinities of the class have been hinted at by King.

No doubt can be entertained, after perusing the admirable memoirs by Morse and Kowalevsky on the embryology of *Terebratula*, *Terebratulina*, *Argiope*, and *Thecidium*, that the genera composing the class and *Amphetrite* possess many important features in common, but almost any Invertebrate groups might be annelidilized by overrating certain points in their affinities. Mr Dall thinks that the general conclusion with reference to the affinities of the Brachiopoda will be something like this. There is much reason for supposing that all the Molluscs and Molluscoids came from the stock out of which the Worms have developed. Indeed, as Huxley has said, they are only isomerous Worms with many special modifications. It is natural, therefore, that the oldest and lowest forms should retain many of the characteristics of the oldest and most simple Worms, especially those which have been modified by a tubular habit. But, on the whole, the modifications are so important that we may continue to consider (if in the specializing tendency of present study we can retain any general divisions of Invertebrates) that the Molluscoids and Molluscs do form two groups somewhat aside from others, and somewhat more nearly related to each other than to the divisions external to them. Therefore, although it may turn out that the Brachiopoda constitute a class close to the Annelids, it cannot be denied that they possess many molluscan characters that cannot be overlooked, and are, under any circumstances, entitled by their importance and numerous distinctive features to constitute a well-defined and separate class.

The name BRACHIOPOD (βραχίων, an arm, πούς, ποδός, a foot) was proposed for the class by Cuvier in 1805, and by Dumeril in 1809, and has since been very extensively adopted. Blainville in 1824 proposed as a substitute for the Cuvierian name that of Palliobranchiata (*pallium*, a mantle; *branchiæ*, gills), on account of the respiratory system being combined with the mantle on which the vascular ramifications are distributed. Prof. King has always adopted the latter name, and perhaps rightly objects to Cuvier's on the ground that it is a misnomer, for the two variously curved and cirrated brachial or labial appendages, improperly designated as arms or feet, were subsequently found not to subserve the function of locomotive organs. Name.

Before describing the various parts of the animal and its shell, it may be as well to mention that it had been many times suggested by Owen, Bronn, Huxley, Gill, and others, that the class could be advantageously divided into two primary groups. Thus, for the first division, including *Lingula*, *Discina*, &c., the names Lyopomata (Owen, 1858), Two divisions.

Pleuropygia (Bronn, 1862), Inarticulata (Huxley, 1869), Lyopomata (Gill, 1871), have been made use of; while for the second division, comprising *Terebratula*, *Rhynchonella*, &c., the names Athropomata (Owen, 1858), Apygia (Bronn, 1862), Articulata (Huxley, 1869), Arthro-

pomata (Gill, 1871) have been proposed. Prof. King, considering these names to be objectionable, and in some cases inadmissible on certain grounds, in 1873 substituted the name *Tretenterata* for the first group, the intestine being provided with an anal aperture, while the second group, to which he gives the name of *Clistenterata*, would embrace animals that are destitute of that organ; but it must also be remembered that the presence or absence of an anal aperture has been ascertained in only three or four recent genera, and that we are compelled, in a measure, to take for granted that what we find to be the case in *Lingula* and *Terebratula* is also so in the many extinct families and genera of which the animal cannot be examined.

With the character above enounced, we generally find structural modifications of the hinge and other differences in the animal, and especially so in what relates to the muscular system. In the opinion of Prof. King the absence of an anal vent in the Clistenterata makes them inferior to the aniferous Tretenterates.

The animal of the Brachiopod is in all cases protected by a shell composed of two distinct valves; these valves are always, except in cases of malformation, equal-sided, but not equivalved. The valves are, consequently, essentially symmetrical, which is not the case with the Lamellibranchiata or Conchifera,—so much so, that certain Brachiopod shells received the name *Lampades*, or lamp shells, by some early naturalists; but while such may bear a kind of resemblance to an antique Etruscan lamp, by far the larger number in no way resemble one. The shell is likewise most beautiful in its endless shapes and variations. In some species it is thin, semi-transparent, and glassy, in others massive. Generally the shell is from a quarter of an inch to about four inches in size, but in certain species it attains nearly a foot in breadth by something less in length, as is the case with *Productus giganteus*. The valves are also in some species very unequal in their respective thickness, as may be seen in *Productus Llangollensis*, *Davidsonia Verneuilii*, &c., and while the space allotted to the animal is very great in many species, as in *Terebratula sphæroidalis*, it is very small in others belonging to *Strophomena*, *Leptæna*, *Chonetes*, &c. The ventral valve is usually the thickest, and in some forms is six or seven times as great as the opposite one. The outer surface of many of the species presents likewise the most exquisite sculpture, heightened by brilliant shades, or spots of green, red, yellow, and bluish black. Traces of the original colour have also been preserved in some of the fossil forms; radiating bands of a reddish tint have been often seen in well-preserved examples of *Terebratula hastata*, *T. saculus*, *T. communis*, *T. biplicata*, and of several others. Some specimens of *T. carnea* are of a beautiful pale pink colour when first removed from their matrix, and E. Deslongchamps has described the tint of several Jurassic species.

The valves have been distinguished by various names, but those of *dorsal* and *ventral* are in most general use. The ventral valve is usually the largest, and in many genera, such as *Terebratula* and *Rhynchonella*, has a prominent beak, with a circular or otherwise shaped perforation or foramen at or near its extremity, partly completed by one or two plates, termed a deltidium. Through the foramen passes a bundle of muscular fibres, termed a peduncle, by which the animal is in many species attached to submarine objects during at least a portion of its existence. Other forms show no indication of ever having been attached, while some that had been moored by means of a peduncle during the early portion of their existence have become detached at a more advanced stage of life, the opening becoming gradually cicatrized, as is so often seen in *Strophomena* [illegible], *Orthisina* [illegible], &c. Lastly, some species have adhered to submarine objects by a larger or smaller portion of their ventral valve, as is the case with many forms of *Crania*, *Thecidium*, *Davidsonia*, &c. Some *Cranias* are always attached by the whole surface of their lower or ventral valve, which models itself and fills up all the projections or depressions existing either on the rock, shell, or coral to which it adhered. These irregularities are likewise, at times, reproduced on the upper or dorsal valve. Some species of *Strophalosia* and *Productus* seem also to have been moored during life to the sandy or muddy bottoms on which they lived, by the means of tubular spines of greater or lesser length. The interior of the shell varies very much according to families and genera. On the inner surface of both valves several well-defined muscular vascular and ovarian impressions are observable; they form either indentations of greater or lesser size and depth, or occur as variously shaped projections. In the *Trimerellidæ*, for example, some of the muscles are attached to a massive or vaulted

of both recent and extinct genera. The apophysis is more or less developed in some genera than in others. In certain forms, as in *Terebratula* and *Terebratulina*, it is short and simple, and attached to a small divided hinge-plate, the two riband-shaped lamina being bent upwards in the middle (fig. 15). The cardinal process is prominent, and on each side of the hinge-plate are situated the dental sockets; the loop in *Terebratulina* becomes annular in the adult by the union of the oral processes or crura (fig. 16). In *Waldheimia* it is elongated and reflected; the hinge-plate large, with four depressions, under which originates a mesial septum, which extends more or less into the interior of the shell (figs. 13 and 14). In *Terebratella* the loop is attached to the hinge-plate and to the septum (fig. 17). In *Megerlia* it is three times attached, first to the hinge-plate, and then to the septum by processes from the diverging and reflected positions of the loop. In *Magas* the apophysary system is composed of an elevated longitudinal septum reaching from one valve to the other, to which are affixed two pairs of calcareous lamellæ, the lower ones riband-shaped; attached first to the hinge-plate, they afterwards proceed by a gentle curve near to the anterior portion of the septum, to the sides of which they are affixed; the second pair originate on both sides of the upper edge of the septum, extending in the form of two triangular anchor-shaped lamellæ (fig. 18). In *Bouchardia* the septum only is furnished with two short anchor-shaped lamellæ. Many more modifications are observable in different groups of which the great family *Terebratulidæ* is composed, and which will be found fully described in Davidson's and other authors' works on the Brachiopoda. In *Thecidium* (figs. 3, 4) the interior of the dorsal valve is variously furrowed to receive a testaceous ridge folded in two or more lobes. In the family *Spiriferidæ* there are two conical spires directed outwards, and nearly filling the cavity of the shell (fig. 5); while in *Atrypa* the broad spirally coiled lamellæ are vertical, and directed towards the centre of the valve. In the *Rhynchonellidæ* there are two short slender curved laminæ, while in many genera and even families, such as the *Productidæ*, *Strophomenidæ*, *Lingulidæ*, *Discinidæ*, &c., there exists no calcified support for the labial appendages. The ventral valve in many of the genera is provided with two curved hinge-teeth, which fit into corresponding sockets in the opposite valve, so that the valves cannot be separated without breaking one of the teeth. Nearly all the genera composing the division Clistenterata have their valves articulated, while those forming the Tretenterata have theirs kept in position by the means of muscles especially adapted to that purpose; but in one of the most natural groups, viz., that of the *Productidæ*, we find genera presenting both conditions.

Shell structure. The intimate structure of the shell has been minutely investigated by Dr Carpenter, Prof. King, Dr Gratiolet, and several others, and been found to be distinct from that of the Lamellibranchiata and Gasteropoda. Dr Carpenter informs us that there is not in the shell of the Brachiopoda that distinction between *outer* and *inner* layers, either in structure or mode of growth, which prevails among the ordinary bivalves; that it seems obvious, both from the nature of the shell substance and from the mode in which it is extended, that the whole thickness of the Brachiopod shell corresponds with the outer layer only of the Lamellibranchiata; and that he has occasionally met with a second layer in recent *Terebratulæ*, within the earlier portion of the shell, but confined to only a part of the surface instead of extending beyond it. In some families composing the Clistenterata it consists, according to Prof. King, of three divisions, the innermost and middle ones, which constitute the entire thickness of the valve, being calcareous with a prismatic or fibrous structure, while the oute divisions would consist of a very thin membrane. The innermost and intermediate divisions are in some families traversed by minute tubular canals, which pass from one surface to the other, for the most part in a vertical direction, and at tolerably regular intervals, but just before terminating near the outer surface of the epidermis their orifices suddenly become dilated, the lower half of the canals being often considerably smaller in diameter than the upper half. The canals are occupied by cæcal processes proceeding from the mantle or the fleshy covering of the animal. Their function is, according to Dr Carpenter, branchial or subservient to respiration; but if there exists an outer epidermis, as described by King, which covers their expanded terminations, there would be no communication between the surrounding sea water and the mantle. In the *Rhynchonellidæ* and in some other families the shell structure would, according to Dr Carpenter, consist of flattened prisms of considerable length, arranged parallel to each other with great regularity, and obliquely to the surface of the shell, the interior of which is imbricated by their outcrop. In certain genera, such as *Lingula* and *Discina*, no canals traverse the shell from the inner to the outer surface. The shell structure, according to Dr Gratiolet, would consist of two distinct elements, that is to say, a corneous or horny animal substance, and a testaceous one; these occur in alternate layers of unequal thickness. The testaceous layers recall the structure observable in the *Terebratulidæ*, being traversed by numerous canals of extreme or microscopic minuteness. As Mr Woodward observes in his excellent manual of the Mollusca, Prof. Huxley has suggested that the cæca are analogous to the vascular processes by which in many Ascidians the *tunic* adheres to the *test*, the extent of which adhesion varies in closely allied genera. It seems, however, strange that these tubular perforations should not have been essential to the species of every family composing the class if they are really subservient to respiration. The subject will therefore demand further consideration.

The anatomy of the Brachiopoda has been the subject of elaborate investigations by Cuvier, Vogt, Huxley, Hancock, Gratiolet, Woodward, Deslongchamps, King, and others, while of late years much light has been likewise thrown on the embryology and early stages of the groups by Steenstrup, Lacaze-Duthiers, Morse, F. Müller, Oscar Schmidt, M'Crady, Kowalevsky, and others. Some differences in opinion, it is true, have been and still are entertained with respect to the exact function to be attributed to certain parts of the animal, but on all essential questions there is a pretty general agreement. Soft parts of the animal.

According to Morse the Brachiopoda are reproduced by eggs, generally kidney-shaped and irregular, which are discharged from the anterior margin of the shell, and drop just beyond the pallial membrane, hanging in clusters from the setæ. Some uncertainty has prevailed as to whether there is a male and female individual. Lacaze-Duthiers and Morse state that the sexes are separate, and describe them as such in *Thecidium* and *Terebratulina*, and the French zoologist goes so far as to suggest that a difference is even observable in the shell, but the statement requires verification. Prof. Morse describes the embryo of *Terebratulina* with great minuteness during its six stages of development. It is divided into two, three, or four lobes clothed with vibratile cilia, and before becoming attached swims or whirls head foremost by means of vibratile cilia which cover the body. The same distinguished American zoologist describes with equal care the formation of the shell from its first stage of development to the adult condition. Lacaze-Duthiers alludes to two and four eye spots in the embryo of *Thecidium*, and states that the animal appears to be in some measure sensible to light.

The mouth conducts by a narrow œsophagus to a simple stomach which is surrounded by a large granulated liver. Owen's "hearts" have been found to be oviducts, while the true heart consists of a pyriform vesicle appended to the dorsal surface of the stomach. The digestive organs and viscera, as well as the muscles, which take up only a small place in the neighbourhood of the beak, are separated from the great anterior cavity, and protected by a strong membrane in the centre of which the mouth is situated. The nervous system consists of a principal ganglion of no great size.

Both valves are lined by a delicate membrane termed the pallium or mantle; it secretes the shell, and is generally fringed with horny bristles or setæ. It is composed of an outer and inner layer, between which are situated the blood channels or lacunes; in fact, all the internal parts of the shell are lined by the inner layer of the mantle, with the exception of the spots where the muscles attach themselves to the shell. The outer layer lines closely the inner surface of the valves to which it adheres, and in those species in which the shell is traversed by canals there exist, on the surface of the mantle facing the inner surface of the valves, corresponding short cylindrical membranous projections or lacunes, which insert themselves into the small tubular orifices that traverse the shell. The cæcal prolongations do not exist in those genera, such as *Rhynchonella*, where the shell is deprived of tubular perforations. The inner layer is rather thicker than the opposite one, and is covered with vibratile cilia. As stated by Nicholson and other anatomists, the blood channels form a remarkable system of more or less branched tubes, anastomosing with one another, and ending in the cæcal extremities. This, which has been termed by Huxley the arterial system, communicates with the perivisceral cavity by means of two or four organs, which are called pseudo-hearts, and which were at one time supposed to be true hearts. Each pseudo-heart is divided into a narrow, elongated external portion (the so-called "ventricle"), which communicates, as Hancock has proved, by a small apicial aperture with the pallial cavity; and a broad, funnel-shaped so-called "auricle," communicating on the one hand by a constricted neck with the so-called "ventricle," and on the other by a wide patent mouth with a chamber which occupies most of the cavity of the body proper, and sends more or less branched diverticula into the pallial lobes (Huxley). The channels vary in their dispositions and details in different genera, and as they project to some small extent, leave corresponding indentations on the inner surface of the shell, so that their shape and directions can very often be traced on fossil and extinct genera as well as if the animal was still in life; this may be seen in the numerous illustrations appended to Davidson's and other authors' works treating of fossil Brachiopoda. There are usually four principal arterial trunks in each lobe of the mantle; the two central ones run direct to the front, near to which they bifurcate, while the outer ones give off at intervals on the side facing the lateral margin of the valves a series of branches which bifurcate several times. It has been observed by Hancock that the inner lamina of the mantle, and more particularly that portion of it forming the floor of the great pallial sinuses, will undoubtedly assist in purifying the blood. In 1854, in his review of Davidson's great work on British fossil Brachiopoda, Oscar Schmidt called attention to an important anatomical omission, namely, the existence of a vast number of microscopic, flattened, calcareous, denticulated plates or spiculæ on certain parts of the surface of the mantle, and destined, no doubt, to stiffen and protect the portions that contain them; and it was, moreover, observed by Hancock, and afterwards by Deslongchamps, that these calcareous plates are not to be found equally distributed over all the surface of the mantle, but only in those portions in connection with the great lacunes or veins, the labial appendages, and the perivisceral cavity. These spiculæ do not appear to be present in every species, and are totally absent in *Lingula*, *Rhynchonella*, and others. Deslongchamps observes that if we examine the genera *Kraussina*, *Terebratula*, *Terebratulina*, *Megerlia*, and *Platydia*, we have a series wherein the number and consistence of the calcareous portions increase in a very rapid manner, and that the spicules lie over each other several times, leading the observers by insensible degrees to *Thecidium*, in which the spiculæ are soldered together, and incrust the mantle to such an extent that it is no longer distinct from the shell itself.

Brachial or labial appendages

The brachial appendages are a pair of singular organs eminently characteristic of the Brachiopoda; they often are more correctly termed *labial* appendages on account of each member being a prolongation of the lateral portion of the lips or margin of the mouth. The Lamellibranchs or Conchifera have analogous appendages, but very much less developed. They assume different shapes in different genera, and are supported, or otherwise, by the more or less complicated skeleton already described. The labial appendages, whatever may be the shape and convolutions they may assume, fill the larger portion of the cavity of the shell in front of the visceral chamber; they are formed of a membranous tube, fringed on one side with long flexible cirri, and occupy almost the whole of the pallial cavity, but were not capable of being protruded in those families in which they were folded back upon themselves and supported by a calcareous skeleton, as in *Waldheimia*, *Terebratella*, *Megerlia*, &c. Barrett, who has examined the a in life, states that *heimia* cranium, wh appendages being a small loop. Barr its cirri further, th brachial appendages

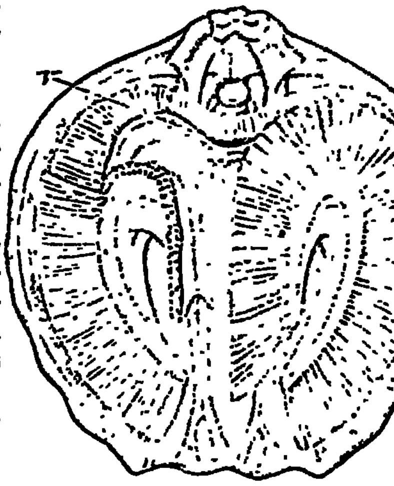

Fig. 19.

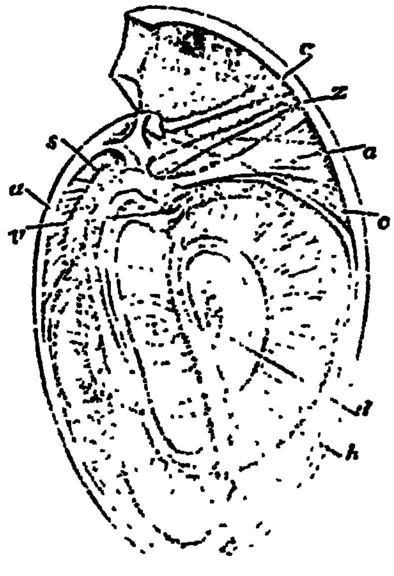
Waldheimia flavescens. Interior of dorsal valve, to show the position of the labial appendages. (A portion of the fringe of cirri has been removed to show the brachial membrane and a portion of the spiral extremities of the arms.)



almost constantly in motion, and often seen to convey small particles to the channel at their base, and that the cirri are bent up when the brachial appendages are retracted, but are generally uncoiled and straightened when the shell is opened, before which the animal has often been observed to protrude a few of its cirri, and move them about to ascertain if any danger threatened. In *Rhynchonella*, where the elongated spiral labial appendages are slightly supported only at their origin by two short calcareous processes, they can at the will of the animal, according to Owen and Morse, be unrolled and protruded to some distance beyond the margins of the valves, and when forcibly stretched out they are said to be more than four times the length of the shell, and to support some 3000 cirri. We may mention, likewise, that Otto Frederick Müller, having dredged from the Lake of Droeback, in Norway, a number of *Terebratulæ* (probably belonging to *Rhynchonella psittacea*), and placed them in a glass of water, he observed that they gracefully extended their spirally coiled brachial appendages. It must, however, remain for ever uncertain whether, in the extinct genera *Spirifera*, *Atrypa*, and others, in which the spirally coiled fleshy labial appendages were supported throughout their entire length by a calcified skeleton, the animal could protrude them beyond the margin of the valves. In some families—*Rhynchonellidæ*, *Productidæ*, and others—these organs are spiral and separate; in many the separation is only at their extremities. There can be very little doubt that these elegant organs, provided as they are with cirri and cilia, are not only instrumental in conveying microscopic organisms to the mouth, which, as seen in fig. 19, is situated between the appendages at their origin, but are likewise subservient to the functions of respiration. Hancock observes that to prove that the brachial organs subserve the function of gills, as well as that of sustentation, it is only necessary to refer to the manner in which the blood circles round the labial appendages and is carried to the cirri, but more particularly to its circulating through these latter organs, and returning direct from them to the heart.

Fig. 21.

As the number and position of the muscles differ materially in the two great divisions into which the Brachiopoda have been grouped, and to some extent also in the different genera of which each division is composed, it may be desirable to treat this subject under two separate heads. Unfortunately almost every anatomist who has written on the muscles of the Brachiopoda has proposed different names for each muscle, and the confusion thence arising is much to be regretted. In the Clistenterata, of which the genus *Terebratula* may be taken as an example, five or six pairs of muscles are stated by Hancock, Gratiolet, and others, to be connected with the opening and closing of the valves, or with their attachment to or movements upon the peduncle. First of all, the adductors or occlusors consist of two muscles, which, bifurcating near the centre of the shell cavity, produce a large quadruple impression on the internal surface of the small valve (fig. 13, *a*, *a'*), and a single divided one towards the centre of the large or ventral valve (fig. 12, *a*). The function of this pair of muscles is the closing of the valves. Gratiolet, who has likewise described with great minuteness the muscles of the Brachiopoda, informs us that those which close and open the valves were the only ones known to Pallas, but that he defined their position and functions clearly. The same was done by Blainville and Quenstedt, but the absence of good figures caused much uncertainty to prevail. This

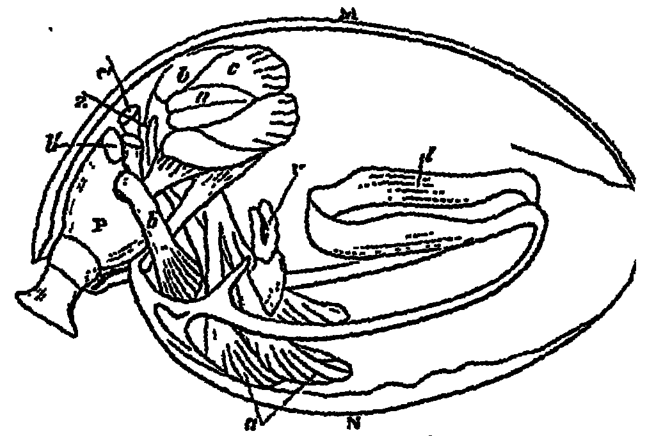

Fig. 22.

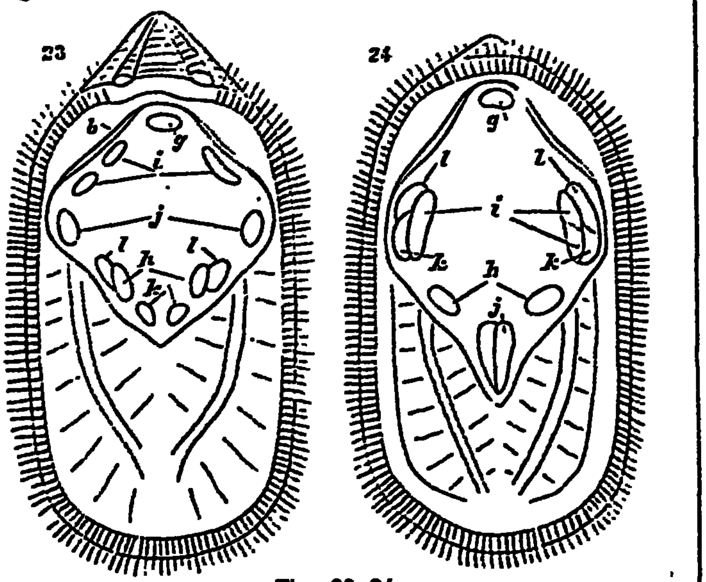
Waldheimia flavescens. Diagram showing the muscular system (*after Hancock*) M, ventral, N, dorsal valve; *l*, loop; V, mouth; Z, extremity of intestine; *a*, adductor; *c*, divaricators; *c'*, accessory divaricators; *b*, ventral adjustors; *b* peduncular muscles; *b''*, dorsal adjustors; P, peduncle.

deficiency was subsequently supplied by Hancock and Gratiolet's admirable illustrations. Two other pairs have been termed *divaricators* by Hancock, or *cardinal muscles* ("muscles diducteurs" of Gratiolet), and have for function the opening of the valves. The divaricators proper are stated by Hancock to arise from the ventral valve, one on each side, a little in advance of and close to the adductors, and after rapidly diminishing in size become attached to the cardinal process, a space or prominence between the sockets in the dorsal valve. The *accessory divaricators* are, according to the same authority, a pair of small muscles which have their ends attached to the ventral valve, one on each side of the median line, a little behind the united basis of the adductors, and again to the extreme point of the cardinal process. Two pairs of muscles, apparently connected with the peduncle and its limited movements, have been minutely described by Hancock as having one of their extremities attached to this organ. The *dorsal adjustors* are fixed to the ventral surface of the peduncle, and are again inserted into the hinge-plate in the smaller valve. The *ventral adjustors* are considered to pass from the inner extremity of the peduncle, and to become attached by one pair of their extremities to the ventral valve, one on each side of and a little behind the expanded base of the divaricators. The function of these muscles, according to the same authority, is not only that of erecting the shell, they serve also to attach the peduncle to the shell, and thus effect the steadying of it upon the peduncle. Gratiolet describes the peduncle with great care, and states it to be composed of two portions—1st, of a horny sheath formed of concentric epidermic layers, very analogous to that which Vogt has described in *Lingula*; and 2d, a fibrous stem enveloped by the sheath. This stem, composed of tendinous fibres, is fixed by its free extremity to different submarine objects; the other extremity passes through the foramen, and is ended by a bulbous projection.

Such is the general arrangement of the shell muscles in the division composing the articulated Brachiopoda, making allowance for certain unimportant modifications observable in the animals composing the different families and genera thereof. Owing to the strong and tight interlocking of the valves by the means of curved teeth and sockets, many species of Brachiopoda could open their valves but slightly. In some species, such as *Thecidium*, the animal could raise its dorsal valve at right angles to the plane of the ventral one (fig. 4).

In the Tretenterata, of which *Lingula* and *Discina* may

be quoted as examples, the myology is much more complicated, and anatomists have differed considerably in their respective views concerning the function of some of the muscles. They have been carefully described by Owen, Vogt, Hancock, Gratiolet Woodward, and others, and more



Figs. 23, 24.

Lingula anatina. 23, interior of ventral valve; 24, interior of dorsal valve (*after King*). *g*, umbonal muscular impressions (open valves); *h*, central muscles (close valves); *i*, transmedial or sliding muscles; *b*, parietal band; *j*, *k*, *l*, lateral muscles (*j*, anteriors; *k*, middles; *l*, outsiders), enabling the valves to move forward and backward on each other.

recently by King, whose views seem to carry with them a greater degree of plausibility. Of the shell or valvular muscles he makes out five pairs and an odd one, and individualizes their respective functions as follows:—Three pairs are *lateral*, having their members limited to the sides of the shell; one pair are *transmedians*, each member passing across the middle of the reverse side of the shell, while the odd muscle occupies the umbonal cavity. The *central* and *umbonal* muscles effect the direct opening and closing of the shell, the *laterals* enable the valves to move forward and backward on each other, and the *transmedians* allow the similar extremities (the rostral) of the valves to turn from each other to the right or the left on an axis subcentrically situated, that is, the medio-transverse region of the dorsal valve. It was long a matter in discussion whether the animal could displace its valves sideways when about to open its shell, but this has been actually observed by Professors Semper and Morse, who saw the animal perform the operation. They mention that it is never done suddenly or by jerks, as the valves are at

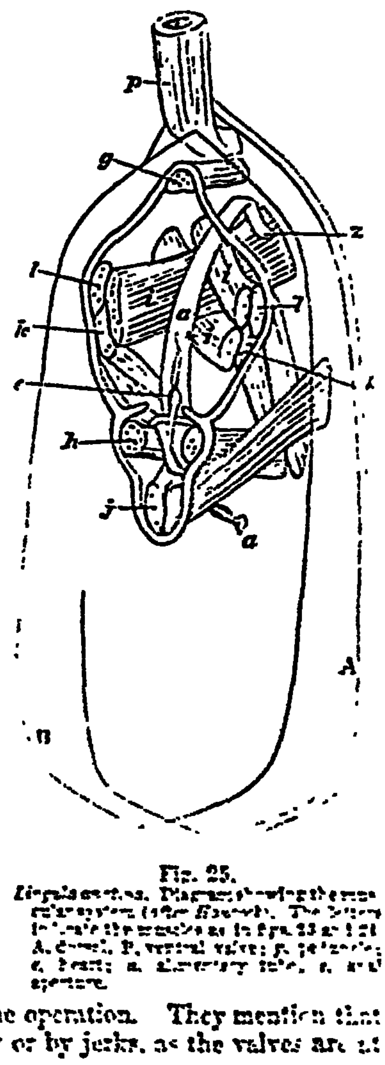


Fig. 25.

[illegible]

first always pushed to one side several times and back again on each other, at the same time opening gradually in the transverse direction till they rest opposite to one another and widely apart. Those who have not seen the animal in life, or who did not believe in the possibility of the valves crossing each other with a slight obliquity, would not consent to appropriating any of its muscles to that purpose, and consequently attributed to all the lateral muscles the simple function of keeping the valves in an opposite position, or holding them adjusted. We have not only the observations of Semper and Morse, but the anatomical investigations of King, to confirm the sliding action or lateral divarication of the valves of *Lingula*.

In the Clistenterata, where no such sliding action of the valves was necessary or possible, no muscles for such an object were required, consequently none took rise from the lateral portions of the valves as in *Lingula*; but in an extinct group, the *Trimerellidæ*, which seem to be somewhat intermediate in character between the Tretenterata and Clistenterata, have been found certain scars, which appear to have been produced by rudimentary lateral muscles, but it is doubtful (considering the shells are furnished with teeth, though but rudely developed), whether such muscles enabled the valves, as in *Lingula*, to move forward and backward upon each other. We do not yet possess any reliable observations as to the manner in which *Discina* opens its valves, but Mr Barrett, who observed *Crania* in life, informs us that the valve opens by moving upon the straight hinge, without sliding the valve. There are muscles connected with other portions of the animal in both groups, such as the *parietal* muscles, strongly defined in the Tretenterata, and distinctive peculiarities of the peduncle, but the limited space at our disposal will not admit of entering upon further anatomical details.

Range of depth.

The Brachiopoda all inhabit the sea, and are supposed to have attained their full growth in a single season. A vast amount of important and accurate information has been collected during the past ten years with respect to the geographical distribution of recent species, as well as to the marine depths they inhabit or prefer. This important knowledge is mainly due to the numerous well conducted and equipped dredging expeditions carried on by private individuals and by the Governments of the leading maritime states. It would not be possible to give here the names of all those naturalists who have contributed to this portion of our information, but we cannot pass over those of Edward Forbes, J. G. Jeffreys, W. B. Carpenter, W. H. Dall, W. Thomson, E. Suess, A. Adams, H. Cuming, &c. Previous to these investigations the data we possessed with respect to the habitat and ranges of depth were in most cases vague and unsatisfactory. It has been ascertained that the Brachiopoda are much localized, and usually

sand by the sliding motion of the two valves, using at the same time the fringes of setæ, which swing promptly back and forth like a galley of oars, leaving a peculiar tract in the sand. In the motion of the setæ he noticed the impulse commencing from behind and running forward. *Discina* has been found attached to stones at low water mark, and dredged from depths ranging from 5 to nearly 2000 fathoms. They are very often clustered together in vast numbers, each adhering by its peduncle to the surface of the shell of its neighbour, one above the other, till they form a living mass of considerable breadth and thickness. *Crania* is found in great numbers adhering to stones and shells at depths of from 18 to 530 fathoms. The genera and species of the Clistenterata live at depths ranging from about half tide mark to that of 2600 fathoms. *Terebratulina caput serpentis* was found by the late R. T. Loweliviry attached to rocks at low water mark on a part of the Scottish coast, where the tide falls only a few feet, but the same species has been dredged alive from depths varying from 3 to upwards of 150 fathoms. Prof. Jukes got immense numbers of specimens of *Waldheimia flavescens* or *Australis* while boating in Australia among the reefs. They were merely washed by the tide, and he gathered them with his hand like limpets on the shore. M. Vélain picked up a small species of *Kraussina* in vast numbers on the shore in the interior crater of the island of St Paul, the shell being alternately covered with water and left dry at every tide. *Kraussina rubra*, from the coast of Natal in South Africa, was described by Dr Gray as having been found attached in great numbers to ascidia and stems of sea-weeds, and Mr Jeffreys had also previously noticed a small European species similarly fixed to sea-weeds. In general, however, it may be said that the larger number of species inhabit depths varying from 5 to 300 or 400 fathoms. Several species live attached to coral reefs. *Waldheimia cranium* has been obtained from depths varying from 160 to 228 fathoms. Barrett and Jeffreys state that *Terebratulina caput serpentis* manifested a remarkable power and disposition to move on its peduncle, and that it was incessantly opening and folding its brachial appendages, and drawing in and sucking in, by means of the whirlpool thus caused, every animalcula within its influence.

Classification. It is now necessary to say a few words with reference to the classification of the Brachiopoda, and in drawing up any scheme of arrangement due regard must be paid to the extinct forms, which vastly outnumber those of the present seas. The first species belonging to the class were imperfectly and quaintly described as well as figured by Fabio Columna as far back as 1606. Since then so many palæontologists have contributed to the elucidation of the fossil species that it would not be possible to give all their names; we must not, however, omit to record those of Linnæus, Defrance, Von Buch, Alcide D'Orbigny, De Blainville, Sowerby, Barrande, De Verneuil, Deslongchamps (father and son), De Koninck, E. Suess, W. King, F. M'Coy, J. Hall, Billings, Dalman, Dall, Fischer, Pander, C. Moore, Eichwald, Kutorga, Keyserling, Sandberger, Sequenza, Salter, Morris, Meek, and Davidson.

Various schemes of classification have been proposed, but none as yet can be said to be more than provisionally satisfactory, because before one can classify it is necessary to understand all the characters of the species one has to arrange in their more or less natural groups, and we are not yet in possession of all that necessary information.

In 1853 Davidson divided the Brachiopoda into eight families, comprising twenty-four genera and about as many sub-genera, but during the years that have elapsed from that to the present time, about seventy more genera and sub-genera have been described, so that as many as one hundred and twenty-three so-termed genera have now to be classed into their respective families, a task which has not yet been satisfactorily accomplished. It is, however, very probable that the number above given has been exaggerated, and that when our knowledge has increased, some of them will have to be placed among the synonyms.

It will be necessary in every scheme of classification to admit the two great divisions Tretenterata and Clistenterata.

The TRETENTERATA would comprise the families *Lingulidæ*, *Discinidæ*, *Craniadæ*, *Trimerellidæ*, and perhaps one or two others.

The CLISTENTERATA would include the families *Terebratulidæ*, *Thecidæidæ*, *Spiriferidæ*, *Rhynchonellidæ*, *Pentameridæ*, *Strophomeridæ*, *Orthidæ*, *Productidæ*, and perhaps two or three others that will have to be characterized. By far the larger number of described genera and species would find their place in this last great division and the above-named families. We will now very briefly notice some of the characters of the families above indicated.

TRETENTERATA—Family 1. *Lingulidæ*.—Shells generally either oblong or circular, with a peduncle, sometimes of considerable length, passing out between the valves or through a narrow channel in the hinge margin; texture horny; no calcified supports for the labial appendages; the fleshy spiral coils directed upwards. This family would comprise the following genera: *Lingula*, *Lingulella*, *Lingulops*, *Lingulepis*, *Glottidia*, *Monobolina*, *Obolus*, *Obolella*, *Dignomia*, *Schmidtia*, *Acritis*, *Volborthia*, &c. *Lingulella* is one of the oldest known types of animal life, while *Lingula* appeared for the first time about the middle of the Cambrian period, and has continued to be represented up to the present time.

Family 2. *Discinidæ*.—Shells more or less circular or oval shaped, attached by a peduncle passing through a foramen in the ventral valve; shell calcareous or horny; setæ extremely long, barbed with cilia of great length; labial appendages fleshy, curved backwards, with small terminal spire directed downwards as in *Crania* (fig. 11). Genera—*Discina*, *Trematis*, *Discinisca*, *Kutorgina* (?), *Acrotrata* (?), *Siphonotrata* (?). *Discina* appeared about the middle of the Cambrian period, and has continued to exist up to the present time.

Family 3. *Craniadæ*.—Shells orbicular or limpet-like, entirely free or attached by a greater or lesser extent of the under surface of their ventral valve; labial appendages spirally coiled, directed towards the bottom of the dorsal valve (fig. 11); shell calcareous, perforated by minute canals. Genera—*Crania*, *Craniops*, *Craniscus*, *Pholidops*. The genus *Crania* appeared for the first time during the Silurian period, and has continued to be represented up to the present time.

Family 4. *Trimerellidæ*.—Shells transversely or longitudinally oval; ventral valves usually the largest and flattest, with a more or less developed beak and area; ventral valves generally the most convex; hinge rudely or faintly dentary; all the genera are provided with a solid or vaulted muscular platform in the interior of both valves; no calcareous support for the labial appendages; shell calcareous, and in two of the genera very massive. All the forms are extinct. Genera—*Trimerella*, *Monomerella*, *Dinobolus*. The species of this family are restricted to the Silurian period.

CLISTENTERATA—Family 5. *Terebratulidæ*.—Shells very variable in shape, with a prominent beak, truncated by a circular perforation, partly completed by a deltidium in one or two pieces; labial appendages united to each other by a membrane, variously folded upon themselves, and in some genera spiral at their extremities. These appendages are entirely or partially supported by a calcified process,

assuming great variety of shape (figs. 1, 12 to 20, and 22). All the species lived attached to submarine bodies by the means of a peduncle. Shell structure punctated. Genera —*Terebratula, Terebratulina, Terebratella, Waldheimia, Megerlia, Kraussina, Kingina, Terebrirostra, Magas, Mannia, Bouchardia, Platidia, Argiope, Cistella, Reusselaria, Zellania, Gwynia, Macandrevia, Diclasma, Megantheris, Stringocephalus, Tropidolepis* (?). *Terebratula* appeared at the conclusion of the Silurian period, and continues to be represented up to the present time, but the larger number of genera have had a very limited distribution in time.

Family 6. *Thecidœdæ*.—Shells small, thick, varied in shape, attached by a larger or smaller portion of the shell substance of their ventral valve; area flat; deltidium indistinct; valves articulated; loop in the dorsal valve folded into two or more lobes lying in hollows of corresponding shape excavated in the substance of the valve (figs. 3, 4). This loop, or apophysary ridge, supports the brachial membrane, whose thickened cirrated margin is apparently attached to the inner sides of the grooves; shell structure punctated. Only one genus, *Thecidium*. It appeared in the Trias, and has continued to be represented up to the present time.

Family 7. *Spiriferidæ*.—Shells variable in shape, ovate, elongated or transverse trilobed, with the hinge-line at times straight and extended into wing-shaped expansions; valves articulated, with or without a flattened area in ventral valve; animal free or attached during at least a portion of its existence by the means of a peduncle, or by muscular fibres issuing from an angular or circular foramen in the beak or area of the ventral valve; dorsal valve internally furnished with two calcareous spiral processes, connected in different manners, and directed outwards towards the sides of the shell (fig. 5). These processes afforded support to the brachial appendages. This family composes the following impunctate or punctate genera: *Spirifera, Cyrtia, Spiriferina, Cyrtina, Martinia, Athyris, Merista, Meristina, Retzia, Nucleospira, Trematospira, Rhynchospira, Meristella, Zygospira, Coelospira, Rhynchoema, Uncites, Ambocœlia, Charionella, Syringothyris, umetria, Suessia, Vetulina* (?). The first species belong g to this family made its appearance during the Silurian eriod, and the family became entirely extinct in the nferior Oolite.

Family 8. *Rhynchonellidæ*.—Valves articulated, very ariable in shape, more or less trigonal, often trilobed or vate, smooth or plicated (fig. 2); foramen beneath a sually produced and pointed beak, completed by a eltidium at times concealed; brachial appendages fleshy nd spirally rolled, flexible, and supported only at their rigin by a pair of short-curved shelly processes, or hroughout by two broad spirally-coiled lamellæ (these pires are vertical, closely appressed, and directed towards he centre of the valve); shell structure fibrous and npunctate. This family composes the following genera: *Rhynchonella, Atrypa, Eatonia, Leptocœlia, Brachymerus, nastrophia, Leiorhynchus, Camarophoria, Rhynchopora, Rhynchonellina*, and one or two others. The first species ppeared during the Silurian period, and representatives the family have continued to the present time.

Family 9. *Pentameridæ*.—Shells ovate, somewhat entagonal; valves articulated, without hinge-area; ramen angular; no deltidium; inside of ventral valve wo contiguous vertical septa of greater or lesser length, which coalesce into one median plate, and then diverge to rm the dental plates, enclosing a triangular trough-like amber. In the interior of dorsal valve are two longitu-nal septa of variable dimensions, to which the socket walls nverge and which they join, forming two more or less de-ed and inclined plates, to the produced extremities of which were no doubt affixed the fleshy spiral labial appendages. Shell structure impunctate. Genera—*Pentamerus, Pentamerella*, and perhaps one or two others. The species of this family are limited to the Silurian, Devonian, and Carboniferous periods.

Family 10. *Strophomenidæ* (figs. 6, 7).—Shells semicircular, transverse, or elongated; valves usually concavo-convex, regularly arched, geniculated or depressed, so that the valve which is convex in some species is concave in others, and *vice versa*; hinge-line long, straight; area in ventral valve flat, with a fissure partly arched over by a pseudo-deltidium, while the extremity of the beak is either entire or perforated by a small circular foramen. In the dorsal valve the projecting bifid cardinal process fills up almost the entire cavity of the fissure that may not have been arched over by the pseudo-deltidium of the opposite valve. Valves sometimes uniformly convex, the dorsal one sometimes depressed with an area divided by a triangular foramen. In the interior of the dorsal valve a small, simple, projecting cardinal process is situated between prominent socket walls, to the inner extremities of which were (probably) attached the brachial appendages. Genera —*Strophomena, Streptorhynchus, Strophodonta, Leptæna, Orthis, Orthesina, Skenidium, Brachyprion, Discolosia, Meekella, Davidsonia* (?), and several others. The first species appeared during the Silurian period, and the last in the upper Lias. It may, however, be necessary to group the genera provisionally placed in the *Strophomenidæ* into one or two families or sub-families. A family *Orthidæ* might be established. *Strophomena* differs from *Orthis* in having a closed fissure, and the cardinal process bifid or trilobed, while in *Orthis* it is generally formed of one piece. In *Strophomena* it is situated directly between the dental sockets, or has between them and it a small prominent ridge, or brachial process; for this last is scarcely developed, where it exists, and forms a marked contrast to what we find in the same valve of *Orthis*. There are also four more or less distinctly defined adductor depressions, which are longitudinally parallel to each other, and separated by ridges, while in *Orthis* these four divisions are placed in pairs one above the other.

Family 11. *Productidæ*.—Shells more or less concavo-convex, oval, semi-oval, or angular and generally auriculated; the hinge-line straight, with or without teeth and sockets for the articulation of the valves (fig. 8); surface of ventral valve or hinge-line more or less furnished with tubular spines, sometimes of considerable length; no calcareous processes for the support of the brachial appendages; shell structure perforated by canals; cardinal process prominent, bilobed or trilobed. Under this a narrow longitudinal ridge generally extends to about half (or more) of the length of the valve, and on each side are seen the ramified dendritic impressions, which may be attributable to the adductor muscle. Outside, and in front of these, are the two reniform impressions so characteristic of the family. Genera—*Productus, Strophalonia, Aulosteges, Chonetes, Productella*. The *Productidæ* made their first appearance during the Silurian time, and became extinct at the close of the Palæozoic period.

Assuming that the reader is acquainted with the geological divisions into which the earth's crust has been grouped, it may be observed that the Brachiopoda, after the Trilobites, occupy the most important place in the Cambrian or Primordial fauna. Thus, in 1871, out of 241 species known to Barrande as composing the animal kingdom of that period, 179 are referable to the Trilobites and other Crustaceans, 28 to the Brachiopoda, while 34 species would be divided between the Annelida, Pteropoda, Gasteropoda, Bryozoa, Cystidians, and Sponges. Subsequently to these researches several additional species of

Trilobites and Brachiopoda have been added to the list through the indefatigable exertions of Prof. Linnarsson, Mr Hicks, and others. The Brachiopoda, along with the groups mentioned by Barrande, are in all probability the earliest representatives of life at present known; for Mr Hicks has obtained undoubted examples of *Lingula* or *Lingulella* (*L. primæva*) from the very base of the whole Cambrian series of St David's in Wales. It is impossible for the present to offer more than an approximate comparison, based on numbers, of the genera and species that have existed during the various geological more or less extended periods; and many years will have to pass away before some master mind will be able to grapple with the accumulated observations of a century or more, and reduce the number of genera and species within reasonable limits, from which something like reliable data may be formed. Lyell has stated that nothing is more remarkable in the Silurian strata generally of all countries than the preponderance of the Brachiopoda over other forms of Mollusca. Their proportional numbers can by no means be explained by supposing them to have inhabited seas of great depth, for the contrast between the Palæozoic and the present state of things has not been essentially altered by the late discoveries made in our deep-sea dredgings. We find the living Brachiopoda so rare as to form about one forty-fourth of the whole bivalve fauna, whereas in the Lower Silurian rocks, and where the Brachiopoda reach their maximum, they are represented by more than twice as many species as the Lamellibranchiate bivalves. There may indeed be said to be a continuous decrease of the proportional number of this lower tribe of Mollusca as we proceed from the older to the newer rocks. Owing to the great number of synonyms it would not be possible at present to offer even an approximate statement with reference to the number of known species. Bigsby states that some 1754 species of Cambrian, Silurian, Devonian, and Carboniferous species of Brachiopoda have been found in America; 1905 in Europe. It is probable that as many as between four or five thousand species of Brachiopoda have been described, and it is noteworthy that the species, so immensely abundant during the Cambrian, Silurian, Devonian, and Carboniferous periods, became much less numerous during the Permian and Triassic, while they again became abundant, although comparatively reduced in number, during the Jurassic and Cretaceous periods. In the Tertiaries they had materially decreased in number, and they are represented at the present time by about 100 species. It has also been clearly ascertained that a certain number of genera and species passed from one system or formation into the one that followed it. Thus, approximately, it may be said that nine genera appeared for the first time in the Cambrian system, fifty-two in the Silurian, twenty-one in the Devonian, seven in the Carboniferous, two in the Permian, three in the Triassic, eleven in the Jurassic, five in the Cretaceous, three in the Tertiary, and nine in the recent periods. But what wonderful changes have been operating during the incalculable number of ages in which the creation and extinction of a large number of genera and thousands of species have taken place,—some few only of the primordial or first created genera, such as *Lingula*, *Discina*, and *Crania*, having fought their way and struggled for existence through the entire sequence of geological time. Many were destined to comparatively ephemeral duration, while others had a greater or lesser prolongation of existence.

The importance of the study of the Brachiopoda must be obvious to all. They are, as already stated, among the first well-known indications of life in this world, and they have continued to be very extensively represented up to the present time. They are also very characteristic fossils by which rocks at great distances, whether in New Zealand or Spitzbergen, in the Himalayas or the Andes, can be identified, without its being even necessary for the Palæontologist to visit the district whence the fossils are derived; they are, as Mantell would have termed them, sure medals of creation, the date of their appearance firmly stamped upon them, and their distinctive characters so legibly impressed as to defy misinterpretation. (T. D.)

BRACHYLOGUS, a title applied, for the first time in the middle of the 16th century, to a work which contains a systematic exposition of the Roman law, and which some writers have assigned to the reign of the Emperor Justinian, and others have treated as an apocryphal work of the 16th century. The earliest extant edition of this work was published at Lyons in 1549, under the title of *Corpus Legum per modum Institutionum*; and the title *Brachylogus totius Juris Civilis* appears for the first time in an edition published at Lyons in 1553. The origin of the work may be referred with great probability to the 12th century. There is internal evidence that it was composed subsequently to the reign of Louis le Débonnaire, as it contains a Lombard law of that king's, which forbids the testimony of a clerk to be received against a layman. On the other hand its style and reasoning is far superior to that of the law writers of the 10th and 11th centuries; whilst the circumstance that the method of its author has not been in the slightest degree influenced by the school of the Gloss-writers (Glossatores) leads fairly to the conclusion that he wrote before that school became dominant at Bologna. Savigny, who has traced the history of the *Brachylogus* with great care, is disposed to think that it is the work of Irnerius himself. Its value is chiefly historical, as it furnishes evidence that a knowledge of Justinian's legislation was always maintained in Northern Italy. The author of the work has adopted the *Institutes* of Justinian as the basis of it, and draws largely on the *Digest*, the *Code*, and the *Novells*; whilst certain passages, evidently taken from the *Sententiæ Receptæ* of Julius Paulus, imply that the author was also acquainted with the Visigothic code of Roman law compiled by order of Alaric II. An edition by Professor Bocking was published at Berlin in 1829, under the title of *Corpus Legum sive Brachylogus Juris Civilis*.

BRACTON, HENRY DE, a learned ecclesiastic, who was chief justiciary in the reign of Henry III. He is supposed to have been born at Bratton-Clovelly in Devonshire. He studied at Oxford, where he took the degree of doctor of laws, and is believed to have delivered lectures in that university. He was appointed a justice itinerant for the counties of Nottingham and Derby in 1245, and his name appears as a justiciary or judge of the Aula Regis on the Fine Rolls in 1249 and in each of the next seventeen years, written indifferently Bratton and Bretton, which circumstance has led Selden and others to attribute to him the authorship of the earliest treatise on the law of England in the French tongue, known as Bretone or Bretoun. In 1254 the king assigned to him by letters patent, in which he was designated "dilectus clericus noster," the use of a house in London belonging to William late earl of Derby during the minority of the heir, and in 1263 he was collated to the archdeaconry of Barnstaple. This office, however, he resigned in the following year; and in 1265 he was appointed chief justiciary, and held that office until the end of 1267, when all notice of him ceases. He wrote

a most comprehensive and systematic work on the laws of England in five volumes, entitled *De Legibus et Consuetudinibus Angliæ*, which is modelled after the *Institutes* of Justinian, and is supposed, from internal evidence, to have been completed about the time when he was appointed chief justiciary, as it contains references to changes in the law made shortly before that time, but takes no notice of the statute of Marlborough passed in 52 Henry III. A Latin abridgment of Bracton's work was written by Gilbert de Thornton, who was appointed Chief-Justice of the King's Bench in the 17th year of the reign of Edward I., of which Selden possessed a copy, but no copy of it is at present known to exist. There are numerous MSS. extant of Bracton's work, but only two editions of it have been printed, the first in folio in 1569, the second in quarto in 1640. The text of these editions is identical, as well as the paging.

BRADFORD, a parliamentary and municipal borough of England, situated in the northern division of the West Riding of Yorkshire and the wapentake of Morley, on an affluent of the Aire, 34 miles S.W. of York, 9 miles W. of Leeds, and 192 miles from London by rail. The borough comprises 7220 acres, and is divided into five townships —Bradford, Manningham, Horton, Bowling, and Bolton. Bradford has returned two members to parliament since 1832, was incorporated in 1847, and is governed by a mayor, 15 aldermen, and 45 councillors. The parish includes the thirteen townships of Allerton, Bowling, Bradford, Clayton, Eccleshill, Haworth, Heaton, Horton, Manningham, North Bierley, Shipley, Thornton, and Wilsden, and comprises 34,146 acres. The population of the borough in 1871 was 145,830,—68,905 males and 76,925 females.

During the Saxon period Bradford was included in the parish of Dewsbury; but William the Conqueror, who mentions it in *Domesday Book*, included it in the barony of Pontefract, which he granted to Ilbert de Lacy. The manor of Bradford remained in the hands of the De Lacies until the beginning of the 14th century, when it passed by marriage to the family of the earl of Lancaster, John of Gaunt holding it at the time of his death in 1399. The manor was held by the Crown from that time down to the reign of Charles I., who sold it for a small yearly rent to the corporation of London. Afterwards it passed into the possession of the Marsdens of Hornby Castle, but since 1795 it has been held by the Rawson family, from whom the corporation have recently purchased all manorial rights. In great rapidity. The first mill in Bradford was built in 1798; there were 20 mills in the town in 1820, 34 in 1833, and 70 in 1841; and at the present time there are between 200 and 300, of much greater magnitude than the earlier factories. In the seventy years between 1801 and 1871 the population of the town increased tenfold, during which period the worsted trade has been developed to an astonishing extent. In 1833 Mr (now Sir Titus) Salt developed the alpaca manufacture in the town; mohair was shortly afterwards introduced; and more recently Mr S. C. Lister has introduced the silk and velvet manufacture, having invented a process of manipulating silk waste, whereby what was previously treated as refuse is made into goods that will compete with those manufactured from the perfect cocoon. In the Bradford staple trade alone it is estimated that there is now an annual turn-over of between £60,000,000 and £70,000,000.

Bradford has been greatly improved in appearance during the last few years, many important public buildings having been erected, and new and spacious thoroughfares opened out where narrow and ungainly streets formerly existed. Amongst the more prominent public buildings may be mentioned—St George's Hall, used for public meetings, concerts, &c., and capable of accommodating nearly 4000 persons, built in 1853; the Exchange, built in 1867, at a cost of £40,000; the market buildings, opened in 1872, and the Town-Hall, opened in 1873, and built at a cost of £100,000. The town is built entirely of the freestone which is so plentiful in the district. Many of the warehouses are large and of considerable architectural beauty, and the factories are mostly of great extent, some single establishments giving employment to between 3000 and 4000 workpeople.

The parish church, built in 1485, on the site of an old Norman church, is dedicated to St Peter. The living is valued at £1300 per annum. There was no other church in the town until 1815, when Christ Church was built. In 1838 St James's Church was erected, and between that date and 1853 five others were built. More recently ten additional churches have been built by the Bradford Church Building Society, the last of the ten (St Bartholomew's) being opened in 1872. There are now over twenty churches in the town. The dissenters have upwards of forty places of worship in Bradford, many of which are large and handsome edifices. The Roman Catholics likewise possess several churches.

Park and Lister Park,—each comprising over 50 acres, and also two smaller parks. The first temperance hall in England was erected at Bradford in 1837. There are two court-houses for the holding of the county and West Riding courts; the borough court is held in the town-hall. Numerous political and social clubs flourish in the town. Three daily and four weekly papers are published. Statues of the late Sir Robert Peel and Richard Oastler, "the factory king," were put up in advantageous positions some years ago; and recently the statues of two local commercial celebrities, Sir Titus Salt and Mr S. C. Lister, have been erected. Bradford has communication with all parts of the country by the Midland, Great Northern, Lancashire and Yorkshire, and London and North-Western Railways. A branch canal in connection with the Leeds and Liverpool canal was opened in 1774, but in 1871 it was closed by injunction, in consequence of the polluted condition of its water. Since then, however, it has been purified and re-opened.

In addition to its extensive operations in connection with the worsted trade, Bradford is largely engaged in the machine, stone, coal, and iron trades. The well-known Bowling and Low Moor Ironworks are within a short distance of the town. Formerly a septennial festival was held at Bradford in honour of Bishop Blaize, the patron saint of the wool-combers, but after 1825 it was discontinued. The market days are Monday and Thursday.

BRADFORD, JOHN, was born at Manchester in the early part of the reign of Henry VIII. Being a good penman and accountant, he became secretary to Sir John Harrington, who was paymaster of the English forces in France. Bradford at this time was gay and thoughtless, and to support his extravagance he appropriated some of the money entrusted to him; but being unable to bear the load of his guilt, he made restitution, and relinquished his employment. About 1547 he took chambers in the Inner Temple, and began to study law; but finding divinity more congenial to his taste, he removed, in the following year, to Catherine Hall, Cambridge, where he studied with such assiduity that in little more than a year he was admitted to the degree of master of arts, and was soon after made fellow of Pembroke Hall. Bishop Ridley, who in 1550 was translated to the see of London, sent for him to the metropolis and appointed him his chaplain. In 1553 he was also made chaplain to Edward VI., and became one of the most popular preachers in the kingdom. Soon after the accession of Mary he was arrested on a charge of sedition and confined in the Tower, where he continued a year and a half. During this time he wrote several epistles which were dispersed in various parts of the kingdom. He was afterwards removed to Southwark, and was at last brought to trial before the court in which Gardiner sat as chief, where he defended his principles to the last, in defiance of all attempts to effect his conversion. He was condemned to the flames, and suffered in Smithfield, July 1, 1555. His writings, which consist chiefly of sermons, meditations, tracts, letters, and prayers, have been published in 12mo by the Religious Tract Society.

BRADLEY, DR JAMES, one of the most eminent British astronomers, was born at Sherborne in Gloucestershire in March 1692. He entered Balliol College, Oxford, in 1710, and graduated as B.A. in 1714 and as M.A. in 1717. At the house of his uncle, the Rev. James Pound, himself known as an acute observer, he had found instruments and means for carrying on a regular series of astronomical observations. He became a member of the Royal Society in 1718, and though he took orders in the following year, and was presented to the vicarage of Bridstow, he did not give up his scientific pursuits. He also obtained a small sinecure living in Wales, but in 1721, on his appointment to the Savilian professorship of astronomy at Oxford, he resigned all his ecclesiastical preferments. In 1727 he communicated to the Royal Society his great paper on aberration, a remarkable combination of exact observation and profound induction. Some years afterwards Bradley began his lectures at the Oxford Museum, and in 1742 he was appointed to succeed Harley as astronomer royal. In 1747 his minute observations led him to the second of his great discoveries, the nutation of the earth's axis. The remainder of Bradley's life was devoted to the Greenwich Observatory. In 1748 he succeeded in getting a small grant for instruments from the public funds, and in 1752 he was rewarded with a pension of £250. He continued his labours till 1761, when his health began to give way. He then retired into the country and died at Chalford, Gloucestershire, in July 1762. The immense mass of useful observations left by him at Greenwich was singularly neglected by English astronomers; but since Bessel presented them in systematic form to the world (see BESSEL, vol. iii. p. 616) their true value has been recognized. For an account of Bradley's scientific discoveries see ASTRONOMY and ABERRATION.

Copious information as to Bradley's life and works will be found in Prof. Rigaud's Memoir prefixed to *Miscellaneous Works and Correspondence of the Rev. James Bradley*, 1832.

BRADSHAW, HENRY, an English poet, born at Chester about the middle of the 15th century. Early displaying a taste for religion and literature, he was received while a boy into the Benedictine monastery of St Werberg in that city; and he was afterwards sent to Gloucester (now Worcester) College, Oxford. After studying there for a time with the novices of his order he returned to his convent, where, in the latter part of his life, he applied himself chiefly to the study of history. He died in 1513. His poetry in some respects is not inferior to that of any of his contemporaries. His works are,—(1), *De antiquitate et magnificentia Urbis Cestriæ;* (2), *Chronicon;* (3), *The Life of the Glorious Virgin St Werberg*, printed at London, 1521, 4to, in verse, and now extremely rare. The life of St Werberg forms only part of this work, which contains also a description of the kingdom of Mercia, a life of St Etheldred, a life of St Sexburg, the foundation and history of Chester, and the chronicles of some kings.

BRADSHAW, JOHN, president of the High Court of Justice which tried Charles I., appears to have been born in 1602 at Marple Hill, near Stockport in Cheshire. He was of good family, and is believed to have been connected with Milton, the mother of the latter having married a Bradshaw. At all events, whether connected or not, the two knew and respected each other. Milton gives a highly eulogistic account of Bradshaw's character in his *Defensio Secunda*, and Bradshaw left by will £10 to Milton. His education seems to have been carried on at Stockport free school, and afterwards at Bunbury and Middleton. He was called to the bar at Gray's Inn in April 1627, and in 1645 became a bencher. For some time he acted as judge in the Sheriff-Courts of London. As a lawyer he had considerable chamber practice, especially among those whom Clarendon calls the "factious." In 1644 he was employed by Parliament as one of the prosecutors of the Irish Lords Macguire and Macmahon. In October 1646 he was voted by the Commons as one of the commissioners of the Great Seal, and in March of the following year he was appointed chief-justice of Cheshire. On October 12, 1648, he was raised to the rank of serjeant. In January 1649, when it was found difficult to compose a court of justice for the trial of the king, Bradshaw was proposed as president, and at once elected. His demeanour on the trial is well known, but has been variously judged. He continued to retain the title of Lord President for some time after the trial,

and received large rewards from Parliament for his valuable services. On the formation of a council of state Bradshaw was elected a member, and for three years held office as president. After that time the presidents were elected in rotation, and held their appointment for a month. When, on the 20th April 1653, Cromwell, after dismissing the Parliament, came to dissolve the council, Bradshaw is said to have confronted him boldly, and denied his power to dissolve the Parliament. This story rests on the authority of Ludlow, who was not a witness, and who does not say that Bradshaw was president of the council on that occasion. Bradshaw, an ardent republican, ever afterwards showed himself an uncompromising adversary of Cromwell. He was returned for Cheshire in the Parliament of 1654, and spoke strongly against vesting the power in a single person. He refused to sign the "engagement" drawn up by Cromwell, and in consequence withdrew from Parliament. Some time afterwards he was concerned with Harrison and others in one of the numerous republican conspiracies, and it has even been suspected that he was at least cognizant of some of the fifth monarchy men's desperate plots. He failed to obtain a seat in the Parliament of 1656, and on 1st August of the same year Cromwell ordered him to be dismissed from the chief-justiceship of Chester. It is not quite certain that this order was carried out. After the abdication of Richard Cromwell, Bradshaw again entered Parliament and became a member of the council of state. His health, however, was bad, and his last public effort was a vehement speech on the seizure of Speaker Lenthall, in which he denounced the military despotism of the time. He died on the 22d November 1659, and was buried in Westminster Abbey. His body was disinterred at the Restoration, and exposed on a gibbet along with those of Cromwell and Ireton. Bradshaw's character will be found very differently drawn by Clarendon (*History of the Rebellion*, bk. xi.) and Milton (*Defensio Secunda*).

zealous promoter of the Revolution and suffered in consequence. When the troubles broke out in Ireland in 1690, Brady, by his influence, thrice prevented the burning of the town of Bandon, after James II. had given orders for its destruction; and the same year he was employed by the people of Bandon to lay their grievances before the English parliament. He soon afterwards settled in London, where he obtained various preferments. At the time of his death in 1726 he held the livings of Clapham and Richmond. Besides his version of the Psalms, which was licensed in 1696, he translated Virgil's *Æneid*, and wrote several smaller poems and dramas. His prose works consist of sermons.

BRAGA, a city of Portugal, capital of a district in the province of Minho, is situated on an elevated plain near the River Cavado (*Nabis*), in 41° 43′ N. lat. and 8° 16′ W. long. The city proper, which has extensive suburbs, is surrounded by walls and towers, and has broad and well-built streets. The cathedral, which dates from the 12th century, is an imposing structure, and contains a large number of interesting objects of art. Among the other churches Santa Cruz is pre-eminent. There are also several convents in the city, an archiepiscopal palace, a lyceum, a library, an orphan asylum, and a large hospital; also the ruins of a theatre, a temple, and an aqueduct of Roman workmanship, and a great variety of minor antiquities of different ages. The principal manufactures are fire-arms, jewellery, and cutlery; and weaving and wax-bleaching are also carried on. A large cattle market is held in June and September. About two and a half miles distant is the celebrated sanctuary of Jesus de Monte, to which pilgrimages are frequently made. Population, 18,467.

Braga is identified with the *Bracara Augusta* of the Romans, the capital of the Callaici Bracarii. About the 5th century it became the chief city of the Suevi; it passed successively into the hands of the Goths and the Moors, and was captured from the latter by Alphonso of Castile. It has for a long time been the seat of the primate of Portugal, who also claimed to be head of the Spanish church, and before the conquest of Coimbra and Lisbon it was the residence of the Portuguese court.

and was universally recognized as being without a rival even in that land of song. In 1801 he returned to his native country, and appeared once more at Covent Garden in the opera *Chains of the Heart* by Mazzinghi and Reeve. So great was his popularity that an engagement he had made when abroad to return after a year to Vienna was renounced, and he remained henceforward in England. For nearly forty years from this date his powers continued unimpaired, and he sang occasionally in public till within a year or two of his death, which occurred on the 17th February 1856. There is, perhaps, no other case upon record in which a vocalist of the first rank enjoyed the use of his organ so long; between his first and last public appearances considerably more than sixty years intervened, during forty of which he held the undisputed supremacy alike in opera, oratorio, and the concert-room. Braham was the composer of a number of vocal pieces, which being sung by himself had great temporary popularity, though they had little intrinsic merit, and are now deservedly forgotten. A partial exception must be made in favour of *The Death of Nelson*, which still keeps its place as a standard popular English song.

BRAHE, TYCHO, an illustrious astronomer, descended from a noble family, of Swedish origin, which had settled in Denmark, was born on the 14th December 1546, at Knudstorp, in the county of Schonen. He learned Latin at the age of seven, and studied five years under private tutors. On the death of his father his uncle sent him, in April 1559, to study philosophy and rhetoric at Copenhagen. The great eclipse of the sun, on the 21st of August 1560, happening at the precise time foretold by astronomers, he began to look upon astronomy as something divine; and having purchased the *Ephemerides* of Stadius, he gained some knowledge of the theory of the planets. In 1562 he was sent by his uncle to Leipsic to study law; but astronomy wholly engrossed his thoughts, and he employed all his pocket-money in purchasing books on that science. Having procured a small celestial globe, he used to wait till his tutor went to bed, in order to examine the constellations and learn their names; and when the sky was clear, he spent whole nights in viewing the stars. He returned to Denmark in 1565, but soon left for Wittenberg, whence he was driven by the plague to Rostock. There in the following year his choleric disposition involved him in a duel with a Danish nobleman, in which he had the misfortune to lose part of his nose; but this defect he so skilfully supplied by means of gold, silver, and wax, that it was scarcely perceptible. In 1569 he took up his residence at Augsburg and remained there two years, busily engaged in astronomical and chemical researches. In 1571 he returned to Denmark, and was favoured by his maternal uncle Steno Belle with a convenient place at his castle of Herritzvad near Knudstorp for making his observations, and building a laboratory. But his marrying a peasant girl occasioned a violent quarrel between him and his relatives, and the king was obliged to interpose in order to reconcile them. In 1574, by royal command, he read some lectures at Copenhagen; and the year following he began his travels through Germany, and proceeded as far as Venice. He then resolved to remove his family, and settle at Basel; but Frederick II., unwilling that Denmark should lose the honour of his residence, bestowed upon him for life the Island of Huen in the Sound, for the erection of an observatory and laboratory, and conferred on him a fee in Norway, a pension of two thousand crowns out of the treasury, and the canonry of Roschild, which brought him a thousand more. The first stone of the observatory was laid on the 8th of August 1576. James VI. of Scotland, afterwards James I. of England, on his visit to Denmark to marry the Princess Anne, went to see Tycho Brahe in his retirement at Uranienburg, made him several presents, and wrote some verses in his praise. Soon after the death of King Frederick, the astronomer was deprived of his pension, fee, and canonry. Finding himself unable to defray the expenses of his observatory he went to Copenhagen, whither he carried some of his instruments, and continued his astronomical observations in that city, till, by the order of Christian IV., he was obliged to discontinue them. He then removed his family to Rostock, and afterwards to Holstein in order to solicit Henry Ranzau to introduce him to the emperor; and accordingly he was received by Rudolph II. at Prague with the most gratifying marks of respect. That prince gave him a magnificent house till he could procure for him one better fitted for astronomical observations, assigned him a pension of three thousand crowns, and promised, upon the first opportunity, a fee for him and his descendants. But he did not long enjoy his good fortune; for, on the 24th of October 1601, he died of a strangury, in the 55th year of his age. He was interred in a magnificent manner in the principal church at Prague, where a noble monument was erected to his memory. Shortly before his death he had been joined by Kepler, who owes his fame to the lessons of careful observation and cautious inference impressed on him by Tycho.

The materials for Brahe's life are to be found in Gassendi, *Vita T. Brahei*, 1654. For Brahe's contributions to astronomy, see Grant, *History of Physical Astronomy*, and the article ASTRONOMY.

BRÁHMA SAMÁJ, the new theistic church in India, owes its origin to Rájá Rám Mohan Rái, one of the leading men whom India has produced in later times. Rám Mohan Rái was born in the district of Bardwán in 1772. He mastered at an early age the Sanskrit, Arabic, and Persian languages. Impressed with the fallacy of the religious ceremonies practised by his countrymen, he impartially investigated the Hindu Shastras, the Koran, and the Bible, repudiated the polytheistic worship of the Shastras as false, and inculcated the reformed principles of monotheism as found in the ancient Upanishads of the Vedas. In 1816 he established a society, consisting only of Hindus, in which texts from the Vedas were recited and theistic hymns chanted. This, however, soon died away on account of the opposition it met from the Hindu community. In 1830 the Rájá organized a Hindu society for prayer-meetings, which may be considered as the foundation of the present Bráhma Samáj. The following extract from the trust-deed of the building dedicated to it will show the religious belief and the purposes of its founder. The building was intended to be "a place of public meeting for all sorts and descriptions of people, without distinction, who shall behave and conduct themselves in an orderly, sober, religious, and devout manner, for the worship and adoration of the eternal, unsearchable, and immutable Being, who is the author and preserver of the universe, but not under and by any other name, designation, or title, peculiarly used for and applied to any particular being or beings by any man or set of men whatsoever; and that no graven image, statue, or sculpture, carving, painting, picture, portrait, or the likeness of anything shall be admitted within the said messuage, building, land, tenements, hereditament, and premises; and that no sacrifice, offering, or oblation of any kind or thing shall ever be permitted therein; and that no animal or living creature shall within or on the said messuage, &c., be deprived of life either for religious purposes or food, and that no eating or drinking (except such as shall be necessary by any accident for the preservation of life), feasting, or rioting be permitted

therein or thereon; and that in conducting the said worship or adoration, no object, animate or inanimate, that has been, or is, or shall hereafter become or be recognized as an object of worship by any man or set of men, shall be reviled or slightingly or contemptuously spoken of or alluded to, either in preaching or in the hymns or other mode of worship that may be delivered or used in the said message or building; and that no sermon, preaching, discourse, prayer, or hymns be delivered, made, or used in such worship, but such as have a tendency to the contemplation of the Author and Preserver of the universe, or to the promotion of charity, morality, piety, benevolence, virtue, and the strengthening of the bonds of union between men of all religious persuasions and creeds." The new faith at this period held to the Vedas as its basis. Rám Mohan Rái soon after left India for England, and took up his residence in Bristol, where he died in 1835. The Bráhma Samáj maintained a bare existence till 1841, when Bábu Debendra Náth Tagore, of the Tagore family of Calcutta, devoted himself to it. He gave a printing-press to the Samáj, and established a monthly journal called the *Tattwabodhiní Patriká* to which the Bengali language now owes much for its strength and elegance. About the year 1850 some of the followers of the new religion discovered that the greater part of the Vedas is polytheistic, and a schism took place,—the advanced party holding that nature and intuition form the basis of faith. Between the years 1847 and 1858 branch societies were formed in different parts of India, especially in Bengal, and the new church made rapid progress, for which it was largely indebted to the spread of English education and the labours of the Christian missionaries.

The Bráhma creed was definitively formulated as follows. (1.) The book of nature and intuition supplies the basis of religious faith. (2.) Although the Bráhmas do not consider any book written by man the basis of their religion, yet they do accept with respect and pleasure any charity, and the cultivation of devotional feelings are their rites and ceremonies. They further say, Govern and regulate your feelings, discharge your duties to God and to man, and you will gain everlasting blessedness; purify your heart, cultivate devotional feelings, and you will see Him who is unseen. (14.) Theoretically there is no distinction of caste among the Bráhmas. They declare that we are all the children of God, and therefore must consider ourselves as brothers and sisters.

For long the Bráhmas did not attempt any social reform. But about 1860 the younger Bráhmas, headed by Bábu Kesab Chandra Sen, tried to carry their religious theories into practice by excluding all idolatrous rites from their social and domestic ceremonies, and by rejecting the distinction of caste altogether. This, however, the older members opposed, declaring such innovations to be premature. The theoretical schism now widened into a visible separation, and henceforth the two parties of the Bráhmas were known as the Conservatives and the Progressives. The progressive Bráhmas, or, as they call their church, the "Bráhma Samáj of India," have made considerable progress. They have built a chapel in Calcutta, which is crowded every Sunday evening; and they encourage the establishment of branch Samájes in different parts of the country. The number of avowed Bráhmas probably does not exceed 3000, but the greater part of the educated natives of Bengal sympathize more or less with the movement. (W. W. H.)

BRAHMANISM is a term commonly used to denote a system of religious institutions originated and elaborated by the *Bráhmans*, the sacerdotal and, from an early period, the dominant caste of the Hindú community. In like manner, as the language of the Áryan Hindús has undergone continual processes of modification and dialectic division, so their religious belief has passed through various stages of development broadly distinguished from one another by certain prominent features. The earliest phases of religious thought in India of which a clear idea can now

earliest lyrical effusions of the Āryan settlers in India which have been handed down to posterity. They are certainly not all equally old; on the contrary they evidently represent the literary activity of many generations of bards, though their relative age cannot as yet be determined with anything like certainty. The tenth and last book of the collection, however, at any rate has all the characteristics of a later appendage, and in language and spirit many of its hymns approach very nearly to the level of the contents of the *Atharvan*. Of the latter collection about one-sixth is found also in the *Rigveda*, and especially in the tenth book; the larger portion peculiar to it, though including no doubt some older pieces, appears to owe its origin to an age not long anterior to the composition of the *Brāhmanas*.

The state of religious thought among the ancient bards, as reflected in the hymns of the *Rigveda*, is that of a worship of the grand and striking phenomena of nature regarded in the light of personal conscious beings, endowed with a power beyond the control of man, though not insensible to his praises and actions. It is a nature-worship purer than that met with in any other polytheistic form of belief we are acquainted with,—a mythology still comparatively little affected by those systematizing tendencies which, in a less simple and primitive state of thought, lead to the construction of a well-ordered pantheon and a regular organization of divine government. To the mind of the early Vedic worshipper the various departments of the surrounding nature are not as yet clearly defined, and the functions which he assigns to their divine representatives continually flow into one another. Nor has he yet learned to care to determine the relative worth and position of the objects of his adoration; but the temporary influence of the phenomenon to which he addresses his praises bears too strongly upon his mind to allow him for the time to consider the claims of rival powers to which at other times he is wont to look up with equal feelings of awe and reverence. It is this immediateness of impulse under which the human mind in its infancy strives to give utterance to its emotions that imparts to many of its outpourings the ring of monotheistic fervour.

The generic name given to these impersonations, viz., *deva* ("the shining ones"), points to the conclusion, sufficiently justified by the nature of the more prominent objects of Vedic adoration as well as by common natural occurrences, that it was the beautiful phenomena of light which first and most powerfully swayed the Āryan mind. In the primitive worship of the manifold phenomena of nature it is not, of course, so much their physical aspect that impresses the human heart as the moral and intellectual forces which are supposed to move and animate them. The attributes and relations of some of the Vedic deities, in accordance with the nature of the objects they represent, partake in a high degree of this spiritual element; but it is not improbable that in an earlier phase of Āryan worship the religious conceptions were pervaded by it to a still greater and more general extent, and that the Vedic belief, though retaining many of the primitive features, has on the whole assumed a more sensuous and anthropomorphic character. This latter element is especially predominant in the attributes and imagery applied by the Vedic poets to *Indra*, the god of the atmospheric region, the favourite figure in their pantheon. While the representatives of the prominent departments of nature appear to the Vedic bard as consisting in a state of independence of one another, their relation to the mortal worshipper being the chief subject of his anxiety, a simple method of classification was already resorted to at an early time, consisting in a triple division of the deities into gods residing in the sky, in the air, and on earth. It is not, however, until a later stage,—the first clear indication being conveyed in a passage of the tenth book of the *Rigveda*, that this attempt at a polytheistic system is followed up by the promotion of one particular god to the dignity of chief guardian for each of these three regions. On the other hand, a tendency is clearly traceable in some of the hymns towards identifying gods whose functions present a certain degree of similarity of nature; these attempts would seem to show a certain advance of religious reflection, the first steps from polytheism towards a comprehension of the unity of divine essence. Another feature of the old Vedic worship tended to a similar result. The great problems of the origin and existence of man and universe had early begun to engage the Hindū mind; and in celebrating the praises of the gods the poet was frequently led by his religious, and not wholly disinterested, zeal to attribute to them cosmical functions of the very highest order. At a later stage of thought, chiefly exhibited in the tenth book of the *Rigveda* and the *Atharvaveda*, inquiring sages could not but perceive the inconsistency of such concessions of a supremacy among the divine rulers, and tried to solve the problem by conceptions of an independent power, endowed with all the attributes of a supreme deity, the creator of the universe, including the gods of the pantheon. The names under which this monotheistic idea is put forth are mostly of an attributive character, and indeed some of them, such as *Prajāpati* ("lord of creatures"), *Viśvakarman* ("all-doer"), occur in the earlier hymns as mere epithets of particular gods. But to other minds this theory of a personal creator left many difficulties unsolved. They saw, as the poets of old had seen, that everything around them, that man himself, was directed by some inward agent; and it needed but one step to perceive the essential sameness of these spiritual units, and to recognize their being but so many individual manifestations of one universal principle. Thus a pantheistic conception was arrived at, put forth under various names, such as *Purusha* ("soul"), *Kāma* ("desire"), *Bráhman* (neutr.; nom. sing. *bráhma*) ("devotion, prayer"). Metaphysical and theosophic speculations were thus fast undermining the simple belief in the old gods, until, at the time of the composition of the *Brāhmanas* and *Upanishads*, we find them in complete possession of the minds of the theologians. Whilst the theories crudely suggested in the later hymns are now further matured and elaborated, the tendency towards catholicity of formula favours the combination of the conflicting monotheistic and pantheistic conceptions; this compromise, which makes *Prājapati*, the personal creator of the world, the manifestation of the impersonal *Bráhma*, the universal self-existent soul, leads to the composite pantheistic system which forms the characteristic dogma of the Brāhmanical period.

The spirit of Vedic worship is pervaded by a strong belief in the efficacy of invocation and sacrificial offering. The earnest and well-expressed prayer cannot fail to draw the divine power to the worshipper and make it yield to his supplication; and offerings, so far from being mere acts of devotion which give pleasure to the god, represent the very food and drink which render him vigorous and capable of battling with the enemies of his mortal friend. This intrinsic power of invocation found an early expression in the term *bráhma* (neuter) ("religious devotion, prayer, hymn"); and its independent existence as an active moral principle in shaping the destinies of man became recognized in the Vedic pantheon in the conception of a god, *Brihaspati* or *Brahmanaspati* ("lord of prayer"), the guardian of the pious worshipper. This feature in the Hindū belief could scarcely fail early to engender and foster in the minds of the people feelings of esteem and reverence towards those who possessed the inspired gift of poetical expression, as

well as those who had acquired an intimate knowledge of the various forms of ritual worship. The common term used in the Veda for the officiating priest is *brahmán* (masc.; nom. sing. *brahmā*), originally denoting, it would seem, "one who prays, a worshipper," or "the composer or reciter of a hymn (*bráhman*, n.)" In some passages the word also signifies a special class of priests who officiated as superintendents during sacrificial ceremonies, the complicated nature of which required the co-operation of several priests. It is probable that in most cases the function of the poet or composer of hymns was combined with that of a minister of worship. In the Vedic hymns two classes of society, the royal (or military) and the priestly classes, were evidently recognized as being raised above the level of the *Viś*, or bulk of the Āryan community. These social grades seem to have been in existence even before the separation of the two Asiatic branches of the Indo-European race, the Āryans of Iran and India. It is true that, although the *Athrava*, *Rathaēstāo*, and *Vāstrya* of the *Zend Avesta* correspond in position and occupation to the *Brāhman*, *Rājan*, and *Viś* of the Veda, there is no similarity of names between them; but this fact only shows that the common vocabulary had not yet definitely fixed on any specific names for these classes. Even in the Veda their nomenclature is by no means limited to a single designation for each of them. Moreover, *Atharvan* occurs not infrequently in the hymns as the personification of the priestly profession, as the proto-priest who is supposed to have obtained fire from heaven and to have instituted the rite of sacrifice; and although *ratheshtha* ("standing on a car") is not actually found in connection with the *Rājan*

contact between the two races. What more natural, therefore, than that measures should have been early devised to limit the intercourse between them within as narrow bounds as possible. In course of time the difference of vocation, and the greater or less exposure to the scorching influence of the tropical sky, added, no doubt, to a certain admixture of Śūdra blood, especially in the case of the common people, seem to have produced also in the Āryan population different shades of complexion, which greatly favoured a tendency to rigid class-restrictions originally awakened and continually fed by the lot of the servile race. Meanwhile the power of the sacerdotal order having been gradually enlarged in proportion to the development of the minutiæ of sacrificial ceremonial and the increase of sacred lore, they began to lay claim to supreme authority in regulating and controlling the religious and social life of the people. The author of the so-called *Purusha-sūkta*, or hymn to Purusha, above referred to, represents the four castes—the *Brāhmanas*, *Kshatriyas*, *Vaiśyas*, and *Śūdras*—as having severally sprung from the mouth, the arms, the thighs, and the feet of Purusha, a primary being, here assumed to be the source of the universe. It is very doubtful, however, whether at the time when this hymn was composed the relative position of the two upper castes could already have been settled in so decided a way as this theory might lead us to suppose. There is, on the contrary, reason to believe that some time had yet to elapse, marked by fierce and bloody struggles for supremacy, of which only imperfect ideas can be formed from the legendary and biassed accounts of later generations, before the Kshatriyas finally submitted to the full measure of priestly pretension

until a later stage,—the first clear indication being conveyed in a passage of the tenth book of the *Rigveda*, that this attempt at a polytheistic system is followed up by the promotion of one particular god to the dignity of chief guardian for each of these three regions. On the other hand, a tendency is clearly traceable in some of the hymns towards identifying gods whose functions present a certain degree of similarity of nature; these attempts would seem to show a certain advance of religious reflection, the first steps from polytheism towards a comprehension of the unity of divine essence. Another feature of the old Vedic worship tended to a similar result. The great problems of the origin and existence of man and universe had early begun to engage the Hindū mind; and in celebrating the praises of the gods the poet was frequently led by his religious, and not wholly disinterested, zeal to attribute to them cosmical functions of the very highest order. At a later stage of thought, chiefly exhibited *in the tenth book of the Rigveda and the Atharvaveda*, inquiring sages could not but perceive the inconsistency of such concessions of a supremacy among the divine rulers, and tried to solve the problem by conceptions of an independent power, endowed with all the attributes of a supreme deity, the creator of the universe, including the gods of the pantheon. The names under which this monotheistic idea is put forth are mostly of an attributive character, and indeed some of them, such as *Prajāpati* ("lord of creatures"), *Viśvakarman* ("all-doer"), occur in the earlier hymns as mere epithets of particular gods. But to other minds this theory of a personal creator left many difficulties unsolved. They saw, as the poets of old had seen, that everything around them, that man himself, was directed by some inward agent; and it needed but one step to perceive the essential sameness of these spiritual units, and to recognize their being but so many individual manifestations of one universal principle. Thus a pantheistic conception was arrived at, put forth under various names, such as *Purusha* ("soul"), *Kāma* ("desire"), *Bráhman* (neutr.; nom. sing. *bráhma*) ("devotion, prayer"). Metaphysical and theosophic speculations were thus fast undermining the simple belief in the old gods, until, at the time of the composition of the *Brāhmanas* and *Upanishads*, we find them in complete possession of the minds of the theologians. Whilst the theories crudely suggested in the later hymns are now further matured and elaborated, the tendency towards catholicity of formula favours the combination of the conflicting monotheistic and pantheistic conceptions; this compromise, which makes *Prājapati*, the personal creator of the world, the manifestation of the impersonal *Bráhma*, the universal self-existent soul, leads to the composite pantheistic system which forms the characteristic dogma of the Brāhmanical period.

The spirit of Vedic worship is pervaded by a strong belief in the efficacy of invocation and sacrificial offering. The earnest and well-expressed prayer cannot fail to draw the divine power to the worshipper and make it yield to his supplication; and offerings, so far from being mere acts of devotion which give pleasure to the god, represent the very food and drink which render him vigorous and capable of battling with the enemies of his mortal friend. This feature in the Hindū belief could scarcely fail early to engender and foster in the minds of the people feelings of esteem and reverence towards those who possessed the inspired gift of poetical expression, as

well as those who had acquired an intimate knowledge of the various forms of ritual worship. The common term used in the Veda for the officiating priest is *brahmán* (masc.; nom. sing. *brahmā*), originally denoting, it would seem, "one who prays, a worshipper," or "the composer or reciter of a hymn (*bráhman*, n.)" In some passages the word also signifies a special class of priests who officiated as superintendents during sacrificial ceremonies, the complicated nature of which required the co-operation of several priests. It is probable that in most cases the function of the poet or composer of hymns was combined with that of a minister of worship. In the Vedic hymns two classes of society, the royal (or military) and the priestly classes, were evidently recognized as being raised above the level of the *Vis'*, or bulk of the Āryan community. These social grades seem to have been in existence even before the separation of the two Asiatic branches of the Indo-European race, the Āryans of Iran and India. It is true that, although the *Athrava*, *Rathaēstāo*, and *Vāstrya* of the *Zend Avesta* correspond in position and occupation to the *Brāhman*, *Rājan*, and *Vis'* of the Veda, there is no similarity of names between them; but this fact only shows that the common vocabulary had not yet definitely fixed on any specific names for these classes. Even in the Veda their nomenclature is by no means limited to a single designation for each of them. Moreover, *Atharvan* occurs not infrequently in the hymns as the personification of the priestly profession, as the proto-priest who is supposed to have obtained fire from heaven and to have instituted the

contact between the two races. What more natural, therefore, than that measures should have been early devised to limit the intercourse between them within as narrow bounds as possible. In course of time the difference of avocation, and the greater or less exposure to the scorching influence of the tropical sky, added, no doubt, to a certain admixture of Śūdra blood, especially in the case of the common people, seem to have produced also in the Āryan population different shades of complexion, which greatly favoured a tendency to rigid class-restrictions originally awakened and continually fed by the lot of the servile race. Meanwhile the power of the sacerdotal order having been gradually enlarged in proportion to the development of the minutiæ of sacrificial ceremonial and the increase of sacred lore, they began to lay claim to supreme authority in regulating and controlling the religious and social life of the people. The author of the so-called *Purusha-sūkta*, or hymn to Purusha, above referred to, represents the four castes—the *Brāhmanas*, *Kshatriyas*, *Vaiśyas*, and *Śūdras*—as having severally sprung from the mouth, the arms, the thighs, and the feet of Purusha, a primary being, here assumed to be the source of the universe. It is very doubtful, however, whether at the time when this hymn was composed the relative position of the two upper castes could already have been settled in so decided a way as this theory might lead us to suppose. There is, on the contrary, reason to believe that some time had yet to elapse, marked by fierce and bloody struggles for supremacy, of which only imperfect ideas can be formed from the legendary and biassed

to each of them. These laws are conceived with no humane or sentimental scruples on the part of their authors. On the contrary, the offences committed by Brāhmans against other castes are treated with remarkable clemency, whilst the punishments inflicted for trespasses on the rights of higher classes are the more severe and inhuman the lower the offender stands in the social scale. The three first castes, however unequal to each other in privilege and social standing, are yet united by a common bond of sacramental rites (*sanskāras*), traditionally connected from ancient times with certain incidents and stages in the life of the Āryan Hindū, as conception, birth, name-giving, the first taking out of the child to see the sun, the first feeding with boiled rice, the rites of tonsure and hair cutting, the youth's investiture with the sacrificial thread, and his return home on completing his studies, marriage, funeral, &c. The modes of observing these family rites are laid down in a class of writings called *Grihya-sūtras*, or domestic rules. The most important of these observances is the *upanayana*, or rite of conducting the boy to a spiritual teacher. Connected with this act is the investiture with the sacred cord, ordinarily worn over the left shoulder and under the right arm, and varying in material according to the class of the wearer. This ceremony being the preliminary act to the youth's initiation into the study of the Veda, the management of the consecrated fire and the knowledge of the rites of purification, including the *sāvitrī*, a solemn invocation to *savitri*, the sun, which has to be repeated every morning and evening before the rise and after the setting of that luminary, is supposed to constitute the second or spiritual birth of the Ārya. It is from their participation in this rite that the three upper classes are called the twice-born. The ceremony is enjoined to take place some time between the eighth and sixteenth year of age in the case of a Brāhman, between the eleventh and twenty-second year of a Kshatriya, and between the twelfth and twenty-fourth year of a Vaiśya. He who has not been invested with the mark of his class within this time is for ever excluded from uttering the sacred *sāvitrī* and becomes an outcast, unless he is absolved from his sin by a council of Brāhmans, and after due performance of a purificatory rite resumes the badge of his caste. With one not duly initiated no righteous man is allowed to associate or to enter into connections of affinity. The duty of the Śūdra is to serve the twice-born classes, and above all the Brāhmans. He is excluded from all sacred knowledge, and if he performs sacrificial ceremonies he must do so without using holy mantras. No Brāhman must recite a Vedic text where a man of the servile caste might overhear him, nor must he even teach him the laws of expiating sin. The occupations of the Vaiśya are those connected with trade, the cultivation of the land and the breeding of cattle; while those of a Kshatriya consist in ruling and defending the people, administering justice, and the duties of military profession generally. Both share with the Brāhman the privilege of reading the Veda, but only so far as it is taught and explained to them by their spiritual preceptor. To the Brāhman belongs the right of teaching and expounding the sacred texts, and also that of interpreting and determining of so stringent a nature as to wholly repress it. To marry a woman of a higher caste, and especially of a caste not immediately above one's own, is, however, decidedly prohibited, the offspring resulting from such a union being excluded from the performance of the srāddha or obsequies to the ancestors, and thereby rendered incapable of inheriting any portion of the parents' property. On the other hand, men are at liberty, according to the rules of Manu, to marry a girl of any or each of the castes below their own, provided they have besides a wife belonging to their own class, for only such a one should perform the duties of personal attendance and religious observance devolving upon a married woman. As regards the children born from unequal marriages of this description, they have the rights and duties of the twice-born, if their mother belong to a twice-born caste, otherwise they, like the offspring of the former class of intermarriages, share the lot of the Śūdras, and are excluded from the investiture and the sāvitrī. For this last reason the marriage of a twice born man with a Śūdra woman is altogether discountenanced by some of the later law books. At the time of the code of Manu the intermixture of the classes had already produced a considerable number of intermediate or mixed castes, which were carefully catalogued, and each of which had a specific occupation assigned to it as its hereditary profession. The self-exaltation of the first class was not, it would seem, altogether due to priestly arrogance and ambition; but, like a prominent feature of the post-Vedic belief, the transmigration of souls, it was, if not the necessary, yet at least a natural consequence of the pantheistic doctrine. To the Brāhmanical speculator who saw in the numberless individual existences of animate nature but so many manifestations of the one eternal soul, to union with which they were all bound to tend as their final goal of supreme bliss, the greater or less imperfection of the material forms in which they were embodied naturally presented a continuous scale of spiritual units from the lowest degradation up to the absolute purity and perfection of the supreme spirit. To prevent one's sinking yet lower, and by degrees to raise one's self in this universal gradation, or, if possible, to attain the ultimate goal immediately from any state of corporeal existence, there was but one way,—subjection of the senses, purity of life, and knowledge of the deity. "He" (thus ends the code of Manu) "who in his own soul perceives the supreme soul in all beings and acquires equanimity toward them all, attains the highest state of bliss." Was it not natural then that the men who, if true to their sacred duties, were habitually engaged in what was most conducive to these spiritual attainments, that the Brāhmanical class early learnt to look upon themselves, even as a matter of faith, as being foremost among the human species in this universal race for final beatitude? The life marked out for them by that stern theory of class duties which they themselves had worked out, and which, no doubt, must have been practised in early times at least in some degree, was by no means one of ease and amenity. It was, on the contrary, singularly calculated to promote that complete mortification of the instincts of animal nature which they considered as indispensable to the final deliverance from the revolution of bodily and personal existence.

The pious Brāhman, longing to attain the *summum bonum* on the dissolution of his frail body, was enjoined to pass through a succession of four orders or stages of life, viz., those of *brahmachārin*, or religious student; *grihastha* (or *grihamedhin*), or householder; *vanavāsin* (or *vānaprastha*), or anchorite; and *sannyāsin* (or *bhikshu*), or religious mendicant. Theoretically this course of life was open and even recommended to every twice-born man, his distinctive class-occupations being in that case restricted to the second station, or that of married life. Practically, however, those

to a lonely wood, taking with him his sacred fires and the implements required for the daily and periodical offerings. Clad in a deer's skin, in a single piece of cloth, or in a bark garment, with his hair and nails uncut, the hermit is to subsist exclusively on food growing wild in the forest, such as roots, fruit, green herbs, and wild rice and grain. He must not accept gifts from any one, except of what may be absolutely necessary to maintain him; but with his own little hoard he should, on the contrary, honour, to the best of his ability, those who visit his hermitage. His time must be spent in reading the metaphysical treatises of the Veda, in making oblations, and in undergoing various kinds of privation and austerities, with a view to mortifying his passions and producing in his mind an entire indifference to worldly objects. Having by these means succeeded in overcoming all sensual affections and desires, and in acquiring perfect equanimity towards everything around him, the hermit has fitted himself for the final and most exalted order, that of devotee or religious mendicant. As such he has no further need of either mortifications or religious observances; but "with the sacrificial fires reposited in his mind," he may devote the remainder of his days to meditating on the divinity. Taking up his abode at the foot of a tree in total solitude, "with no companion but his own soul," clad in a coarse garment, he should carefully avoid injuring any creature or giving offence to any human being that may happen to come near him. Once a day, in the evening, "when the charcoal fire is extinguished and the smoke no longer issues from the fireplaces, when the pestle is at rest, when the people have taken their meals and the dishes are removed," he should go near the habitations of men, in order to beg what little food may suffice to sustain his feeble frame. Ever pure of mind he should thus bide his time, "as a servant expects his wages," wishing neither for death nor for life, until at last his soul is freed from its fetters and absorbed in the eternal spirit, the impersonal self-existent Brahmă.

The neuter term *bráhmă* is met with in the *Rigveda* both in the abstract sense of "devotion, worship," and in the concrete one of "prayer, hymn." Closely connected with it is found the masculine term *brahmá*, "a worshipper, a priest." The popular belief in the efficacy of invocation constituted a prominent feature of the Vedic symbolism, which the traditional and professional activity of the poet and minister of worship did, no doubt, much to keep up and foster. In the theosophical speculations of the later Vedic poets this mystic power of devotion found its fullest expression in the recognition of the *bráhmă* as the highest cosmical principle, and its identification with the pantheistic conception of an all pervading self-existent essence, the primary source of the universe. Whether this identification was originally due to some extent to the influence of class-interest possibly aided by the coincidence of name, or whether it was solely the product of a highly-wrought religious imagination, it is difficult to decide. Certain it is, however, that the term *bráhmă* began to be used about the same time as the abstract designation of priestly function and the Brāhmanical order in general, in the same way as the word *kshatra* came to denote the aggregate of functions and individuals of the military class

The tendency towards a comprehension of the unity of divine essence had resulted in some minds, as has been remarked before, in a kind of monotheistic notion of the origin of the universe. In the literature of the Brāhmana period we meet with this conception as a common element of speculation; and so far from its being considered incompatible with the existence of a universal spirit, *Prajāpati*, the personal creator of the world, is generally allowed a prominent place in the pantheistic theories. Yet the state of theological speculation, reflected in these writings, is one of transition. The general drift of thought is essentially pantheistic, but it is far from being reduced to a regular system, and the ancient form of belief still enters largely into it. The attributes of Prajāpati, in the same way, have in them elements of a purely polytheistic nature, and some of the attempts at reconciling this new-fangled deity with the traditional belief are somewhat awkward. An ancient classification of the gods represented them as being thirty-three in number, eleven in each of the three worlds or regions of nature. These regions being associated each with the name of one principal deity, this division gave rise at a later time to the notion of a kind of triple divine government, consisting of *Agni* (fire), *Indra* (sky) or *Vāyu* (wind), and *Sūrya* (sun), as presiding respectively over the gods on earth, in the atmosphere, and in the sky. Of this Vedic triad mention is frequently made in the Brāhmana writings. On the other hand the term *prajāpati* (lord of creatures), which in the *Rigveda* occurs as an epithet of the sun, is also once in the *Atharvaveda* applied jointly to Indra and Agni. In the Brāhmanas Prajāpati is several times mentioned as the thirty-fourth god; whilst in one passage he is called the fourth god, and made to rule over the three worlds. More frequently, however, the writings of this period represent him as the maker of the world and the father or creator of the gods. It is clear from this discordance of opinion on so important a point of doctrine, that at this time no authoritative system of belief had been agreed upon by the theologians. Yet there are unmistakable signs of a strong tendency towards constructing one, and it is possible that in yielding to it the Brāhmans may have been partly prompted by political considerations. The definite settlement of the caste system and the Brāhmanical supremacy must probably be assigned to somewhere about the close of the Brāhmana period. Division in their own ranks was hardly favourable to the aspirations of the priests at such a time; and the want of a distinct formula of belief adapted to the general drift of theological speculation, to which they could all rally, was probably felt the more acutely, the more determined a resistance the military class was likely to oppose to their claims. Side by side with the conception of the Bráhmă, the universal spiritual principle, with which speculative thought had already become deeply imbued, the notion of a supreme personal being, the author of the material creation, had come to be considered by many as a necessary complement of the pantheistic doctrine. But, owing perhaps to his polytheistic associations and the attributive nature of his name, the person of Prajāpati seems to have been thought but insufficiently adapted to represent this abstract idea. The expedient resorted to for solving the difficulty was as ingenious as it was characteristic of the Brāhmanical aspirations. In the same way as the abstract denomination of sacerdotalism, the neuter *bráhmă*, had come to express the divine essence, so the old designation of the individual priest, the masculine term *brahmá*, was raised to denote the supreme personal deity which was to take the place and attributes of the Prajāpati of the Brāhmanas and Upanishads. By this means the very name of the god expressed the essential oneness of his nature with that of the divine spirit as whose manifestation he was to be considered. Even in the later Vedic writings Brahmā is but rarely mentioned; and in some of these passages he is expressly identified with Prajāpati. It is in the institutes of Manu, where, as we have seen, the system of castes is propounded in its complete development, that his definite place is assigned to him in the cosmogony. According to this work, the universe, before undiscerned, was made discernible in the beginning by the sole, self-existent spirit (*brahmă*). He, then, having willed to produce from his own substance various creatures, created the

heavens. The modern god is represented as undergoing, for the benefit of mankind, a number of *avatāras* or incarnations, ten of which are especially dwelt upon by the fervid imagination of his followers. The exact time at which these several episodes were incorporated into the cult of Vishnu cannot at present be ascertained. As they are for the most part conceived in a decidedly Brāhmanical spirit,—the special object for which Vishnu assumes a human form being generally to deliver the people from the oppression of some wicked tyrannous prince,—it is probable that they were mostly introduced at a time when there was still some danger of the Kshatriyas defying the Brāhmanical rule. Of somewhat different origin were, perhaps, two of Vishnu's most popular and important incarnations, viz., those in which he manifests himself in the persons of *Krishna* and *Rāma*, two heroes whose exploits are celebrated in the Mahābhārata and Rāmāyana. It is possible that these warriors and their legendary achievements had been favourite subjects of heroic poetry for some time previous to the overthrow of the Kshatriyas, and that, being already regarded by the latter as representatives of Vishnu, they were afterwards recognized as such by the Brāhmans, and thus gave rise to the system of Avatāras.

The male nature of the triad was supposed to require to be supplemented by each of the three gods being associated with a female energy (*Śakti*). Thus *Vāch* or *Sarasvatī*, the goddess of speech and learning, came to be regarded as the *śakti*, or consort of Brahmā; *Śrī* or *Lakshmī*, "beauty, fortune," as that of Vishnu; and *Umā* or *Pārvatī*, the daughter of *Himavat*, the god of the Himālaya mountain, as that of Śiva. On the other hand, it is not improbable that *Pārvatī*,—who has a variety of other names, such as *Kālī* ("the black one"), *Durgā* ("the inaccessible, terrible one"), *Mahā-devī* ("the great goddess"),—enjoyed already a somewhat extensive worship of her own, and that there may thus have been good reason for assigning to her a prominent place in the Brāhmanical system. In later times a special sect, that of the *Śāktas*, or followers of any one of the *śaktis*, was principally devoted to her service; and up to our own days an almost national festival, the *Durgāpūjā* or *Daśarā*, accompanied by sanguinary sacrifices, is annually, in September or October, celebrated in her honour in Northern and Western India.

A compromise was thus effected between the esoteric doctrine of the metaphysician and some of the most prevalent forms of popular worship, resulting in what was henceforth to constitute the orthodox system of belief of the Brāhmanical community. Yet the Vedic pantheon could not be altogether discarded, forming part and parcel, as it did, of that sacred revelation (*śruti*), which it had been taught was the divine source of all religious and social law (*smriti*, "tradition"), and being, moreover, the foundation of the sacrificial ceremonial on which the priestly authority so largely depended. The existence of the old gods is therefore likewise recognized, but recognized in a very different way from that of the triple divinity. For while the triad represents the immediate manifestation of the eternal, infinite soul—while it constitutes, in fact, the Brahma itself in its active relation to mundane and seemingly material occurrences, the gods are of this world, are individual spirits or portions of the Brahma like men and other creatures, only higher in degree. To them an intermediate sphere, the heaven of Indra (the *svarloka* or *svarga*), is assigned to which man may raise himself by fulfilling the holy ordinances; but they are subject to the same laws of being; they, like men, are liable to be born again in some lower state, and therefore, like them, yearn for emancipation from the necessity of future individual existence. It is a sacred duty of man to worship these superior beings by invocations and sacrificial observances, as it is to honour the *pitris*, the spirits of the departed ancestors. The dead, on being judged by *Yama*, the Pluto of Hindū mythology, are supposed to be either passing through a term of enjoyment in a region midway between the earth and the heaven of the gods, or undergoing their measure of punishment in the nether world, situated somewhere in the southern region, before they return to the earth to animate new bodies. In Vedic mythology Yama was considered to have been the first mortal who died, and "espied the way to" the celestial abodes, and in virtue of precedence to have become the ruler of the departed; in some passages, however, he is already regarded as the god of death. Although the pantheistic system allowed only a subordinate rank to the old gods, and the actual religious belief of the people was probably but little affected by their existence, they continued to occupy an important place in the affections of the poet, and were still represented as exercising considerable influence on the destinies of man. The most prominent of them were regarded as the appointed *Lokapālas*, or guardians of the world; and as such they were made to preside over the four cardinal and (according to some authorities) the intermediate points of the compass. Thus *Indra*, the chief of the gods, was regarded as the regent of the East; *Agni*, the fire (*ignis*), was in the same way associated with the south-east; *Yama* with the south; *Sūrya*, the sun (Ἥλιος), with the south-west; *Varuna*, originally the representative of the all-embracing heaven (Οὐρανός) or atmosphere, now the god of the ocean, with the west; *Vāyu* (or *Pavana*) the wind, with the north-west; *Kubera*, the god of wealth, with the north; and *Soma* (or *Chandra*) with the north-east. In the institutes of Manu the *Lokapālas* are represented as standing in close relation to the ruling king, who is said to be composed of particles of these his tutelary deities. The retinue of Indra consists chiefly of the *Gandharvas* (etym. connected with κένταυρος), a class of genii, considered in the epics as the celestial musicians; and their wives, the *Apsaras*, lovely nymphs, who are frequently employed by the gods to make the pious devotee desist from carrying his austere practices to an extent that might render him dangerous to their power. *Narada*, an ancient sage, is considered as the messenger between the gods and men, and as having sprung from the forehead of Brahmā. The interesting office of the God of love is held by *Kāmadeva*, also called *Ananga*, the bodyless, because, as the myth relates, having once tried by the power of his mischievous arrow to make Śiva fall in love with Pārvatī, whilst he was engaged in devotional practices, the urchin was reduced to ashes by a glance of the angry god. Two other mythological figures of some importance are considered as sons of Śiva and Pārvatī, viz., *Kārttikeya* or *Skanda*, the leader of the heavenly armies, who was supposed to have been fostered by the six *Krittikās* or Pleiades; and *Ganeśa*, the elephant-headed god of wisdom, and at the same time the leader of the *dii minorum gentium*.

Orthodox Brāhmanical scholasticism makes the attainment of final emancipation (*mukti*, *moksha*) dependent on perfect knowledge of the divine essence. This knowledge can only be obtained by complete abstraction of the mind from external objects and intense meditation on the divinity, which again presupposes the total extinction of all sensual instincts by means of austere practices (*tapas*). The chosen few who succeed in gaining complete mastery over their senses and a full knowledge of the divine nature become absorbed into the universal soul immediately on the dissolution of the body. Those devotees, on the other hand, who have still a residuum, however slight, of ignorance and worldliness left in them at the time of their death, pass to the world of Brahmā, where their souls, invested with subtile corporeal frames, await their reunion with the

by far the largest share of adoration, and it is in special accounts of the *Śaiva*, *Vaishnava*, and *Śākta* sects rather than in an exposition of the Brāhmanical belief, that the religious history of India from about the beginning of our era can be dealt with satisfactorily. At that time the worship of Vishnu in his most popular avatār, in the person of *Krishna*, appears to have received much countenance at the hands of the priests, with a view of counteracting the growing influence of Buddhism. The sectarian spirit gave gradually rise to a special class of works, the modern *Purānas* composed for the express purpose of promoting the worship of some particular deity. In the 8th or 9th century *Śankara-āchārya*, a Malabar Brāhman of the Śaiva sect and Vedānta school of philosophy, made an attempt, by engaging in controversy with the leaders of various sects, to restore the Brāhmanical system of belief to its former imposing position. His example and teachings seem to have inspired the Brāhmanical community with a good deal of religious zeal, and even fanaticism, and thus to have greatly contributed to the final overthrow of the Buddhists. In the 7th century the authority of *Śākya-muni's* doctrine was already on the wane, as is evident from Hiouen Thsang's complaints of the number of ruined temples and deserted monasteries, and the great proportion of heretics. At the time of Śankara its decline must have been still more advanced, and a few more centuries probably sufficed to make the last living remains of the Buddhist faith disappear from the continent of India; except, indeed, in Nepal, where it prevails to this day. There also still exists in India a very important sect which seems to have early branched off from the Buddhist doctrine, viz., the *Jains*. Although, in the long run, Buddhism has been unable to maintain the ground it had won from the Brahmans, the humanizing spirit of its doctrines has left a deep impress on the Hindū mind. One of the practical and least salutary effects it has produced is the adoption of monastic institutions by most of the Brāhmanical sects. The *maths* or convents, in which a considerable portion of the clergy of the various religious bodies reside together, are presided over by *mahānts* or superiors, and are scattered all over India. Śankara founded several establishments of this kind in various parts, especially one still existing at Śringeri, on the Western Ghats. In spite of its levelling tendencies, Buddhism seems never to have succeeded in checking the further development of the caste system. At the time of Śankara seventy-two mixed classes, or eighteen subdivisions of each of the four original castes, are said to have existed, and ever since they have become more and more numerous. Indeed, there can be no doubt that Hindūs do not feel, and perhaps never felt, their class restrictions as being in any way burdensome, or still less a disgrace to them, and that even the lowest man looks upon his caste as a privilege as high as that of the Brāhman. In the opinion of the Brāhmans only one original caste is now extant, viz., their own, all the others having resulted from successive intermixtures.

Mr Sherring, in his *Hindu Tribes and Castes*, makes the following remarks on the Brāhmanical caste at the present day:—"The Brahman occupies the highest rank among Hindus for at least three reasons. The first is his assumed sanctity. By the people generally he is regarded as a pure, stainless, twice-born being, divine as well as human, worthy of unbounded admiration and worship. He is the priest of the Hindu religion, directing the ceremonies performed at the temples, sacred wells, sacred tanks, sacred rivers, and at all hallowed places throughout the land. He is present to sanction, and give effect to, the great social festivals of his countrymen held at marriages, at births of sons, and at deaths. He casts the horoscope, tells the lucky days, gives spiritual counsel, whispers *mantras* or mysterious words, executes magical incantations and charms, and is at once household god, family priest, and general preceptor and guide in behalf of the many millions of Hindus residing in the vast country lying between the Himalayas and Cape Comorin. The second reason of the Brahman's superiority is that, for many ages, perhaps from the outset of his career, when with other Aryans he first entered the plains of India, he has been intellectually in advance of the rest of the Hindu race. . . . The third reason is a consequent of the second. The Brahman is not only a thinking, but also a reading man. He possesses and, perhaps, reads the holy canon—Vedas, Shastras, and Purānas. He has been the author of Hindu literature. . . . Light of complexion, his forehead ample, his countenance of striking significance, his lips thin, and mouth expressive, his eyes quick and sharp, his fingers long, his carriage noble and almost sublime, the true Brahman, uncontaminated by European influence and manners, with his intense self-consciousness, with the proud conviction of superiority depicted in every muscle of his face, and manifest in every movement of his body, is a wonderful specimen of humanity walking on God's earth. Yet the Brahman has lived his day. His prestige is rapidly on the decline, and is only maintained at its ancient pitch in remote villages and in the fastnesses of superstition in great cities. Here, as of old, it envelopes him like a glory. But the further he moves from such places, the more dim becomes the glory until it fades away altogether. Education and other influences are treating the Brahman roughly. Yet the fault is his own. He has had a better start by reason of his great natural endowments than any Hindu of the other castes below him; but he has neglected his opportunities. I fear he has been too proud, too self-satisfied to avail himself of them."

On the modern observance of religious duties Professor Wilson remarks:—"Now it is true that in the present constitution of Indian society the distribution of the periods of life, beyond that of the student, is never regarded except by a few, who prefer a life of lazy mendicity, or by some half-crazed enthusiast, who thinks it possible to realize the letter of the law. The great body of the people, Brahmans included, pursue their worldly avocations as long as their faculties permit, spend the decline of life in the bosom of their families, and die peaceably and decently at home. But although the practice is discontinued, the doctrine remains and influences opinion; and devotional ceremonies, pilgrimage, penance, and abstract contemplation have an undue preponderance in the estimation of the people, even the best informed among them, over active duties and the precept of morality. As to the common people they have a still lower scale, and they find a ready substitute for the inconveniences of all moral restraint in the fervour of that faith which they place in Vishnu, and the unwearied perseverance with which they train a parrot or a starling to repeat his names, to articulate Krishna-Rādhā, or Sitā-Rām."

The study of the ancient literature of the Hindūs has taught us that some practices which have hitherto, or until recently, prevailed in India, and which have contributed so much to bringing Hindū morals into disrepute, are but comparatively modern innovations. Thus, the rite of *suttee* (properly *satī*, *i.e.*, "the faithful wife"), or voluntary immolation of widows, which was abolished some thirty years ago with considerable difficulty, seems to have sprung up originally as a local habit among the Kshatriyas, and, on becoming more and more prevalent, to have at length received Brāhmanical sanction. The alleged conformity of the rite to the Hindū scriptures has been shown to have rested chiefly on a misquotation, if not an intentional garbling, of a certain passage of the *Rigveda*, which, so far from authorizing the concremation of the widow, bids her

of bodies imparting the energy; (*b*) to measure directly the amount of frictional resistance between two bodies; or (*c*) to measure, indirectly, the amount of energy given out by the body or system of bodies producing it.

The first case is the familiar one occurring in the brakes of locomotives, railway carriages, and wheeled vehicles generally, and in those applied to such machines as cranes, winches, &c. Here some system of bodies,—or for simplicity's sake we may say some body,—originally at rest has been set in motion, and has received acceleration up to a certain velocity, the work which has been done in that acceleration being stored up as "actual energy" in the body itself. Before it can be brought to rest it must part with this energy, expending it in overcoming some external resistance. Very frequently the actual energy is very large in proportion to the usual resistance opposing the motion of the body, so that that motion would continue for a long time, or through a great distance, before the whole energy had been expended and the body brought to rest. For the sake of convenience, and in certain cases for the sake of safety, it is often necessary that this time or distance should be greatly shortened. This may be done by artificially increasing the resistance for the time being, and the most convenient method of doing this is the use of a brake.

The construction of railway brakes falls to be treated in detail in the article RAILWAYS. In other vehicles the brake belongs generally to one of two classes—it is either a block which can be pressed against a wheel by a suitable arrangement of levers under the control of the driver, or a slipper or "skid" which can be placed under a wheel, and which is attached by a chain or otherwise to the body of the vehicle. The increased resistance is due in the one case to the friction between the block and the wheel, and in the other to that between the skid and the road.

In the case of hoisting-machines the brake is used very frequently as a means of controlling the velocity of the descent of the load. In the process of "lowering by a brake," its frictional resistance is alone opposed to the load, and suitable mechanical means are provided for varying that resistance so that the velocity of the descending weight may be kept within the desired limits. The brake used in these machines very frequently consists of a cylindrical pulley or narrow drum encircled by a flexible belt of iron or steel. One end of this belt is fastened to the framing, and it is so formed that in ordinary work the drum revolves in it without touching it. When necessary, however, the position of the movable end can be so altered as to bring a larger or smaller area into contact, the surfaces being held together with a pressure which can be varied to suit the requirements of each case. This is effected either by a simple lever (in small machines worked by the foot), or for heavier work by the aid of a screw and hand-wheel.

In what are known as "differential" brakes the brake-band is not fixed to the frame of the machine, but both its ends are attached to points in a movable lever in such a way that motion of the lever affects them unequally, tightening one more than it loosens the other, or loosening one more than it tightens the other. The principle of such an arrangement is shown in fig. 1. Here A is the pulley, B the brake-band, and C the working lever; B being attached to the lateral points *a* and *b* unequally distant from the fulcrum D. It is obvious that for any motion of C the angular motions of the arms D*a* and D*b* are equal, but the instantaneous linear motions of the points *a* and *b* in the directions of the band are unequal, varying directly as D*a*, D*b*, the ratio of the normals from D upon those directions. Thus any motion of C to the right tends to tighten the lower part of the belt and to slacken the upper part, but the slackening takes place through a larger distance than the tightening, and the belt is therefore released from the drum. By moving the lever to the left, on the other hand, the opposite action occurs, and the belt is correspondingly tightened.

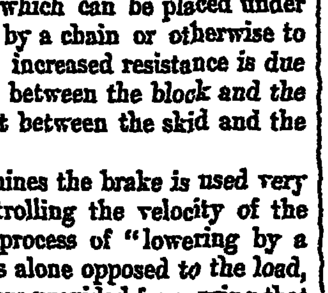

Fig. 1.—Differential Brake.

Instead of using the friction between two solid bodies, in some special cases the frictional resistance of a fluid is employed, as in what Professor Rankine called fan brakes and pump brakes. In the one case the motion of revolving blades (commonly) is opposed by the resistance of the atmospheric or liquid medium surrounding them, and in the other the motion of a liquid is opposed by the resistance due to a narrow passage or orifice.

The measurement of the frictional resistance between two bodies of known material or form is often of great importance, and it is still more often of importance to measure, by means of the frictional resistance which it can balance, the amount of energy given out by some engine or machine. Both these measurements can be and are frequently made by means of brakes. For this purpose the apparatus must be so made that the actual resistance can be accurately measured,—that this resistance can be kept sensibly constant for any length of time, but can be altered at will,—and also that the brake can be kept continuously at work for any desired period. The brake used for this purpose commonly takes the form of a revolving drum of iron, encircled by a ring of hard wood blocks connected together by thin iron bands. To this ring is attached a weight of known magnitude, at a known distance from the centre of the pulley. The wheel being set in motion the blocks can be gradually pressed upon it by a screw until the friction occurring is just sufficient to lift the weight and keep it off the ground or its support. So long as these conditions can be maintained the frictional resistance is exactly known, for its magnitude must be to that of the weight inversely as their distances from the centre of the wheel, and the energy expended in any given time will be equal to this resistance multiplied by the space passed through in the time by any point in the periphery of the drum.

Figs. 2 and 3 show the construction of a brake of this kind, copied from drawings kindly furnished by Mr W. H. Maw, the designer. The

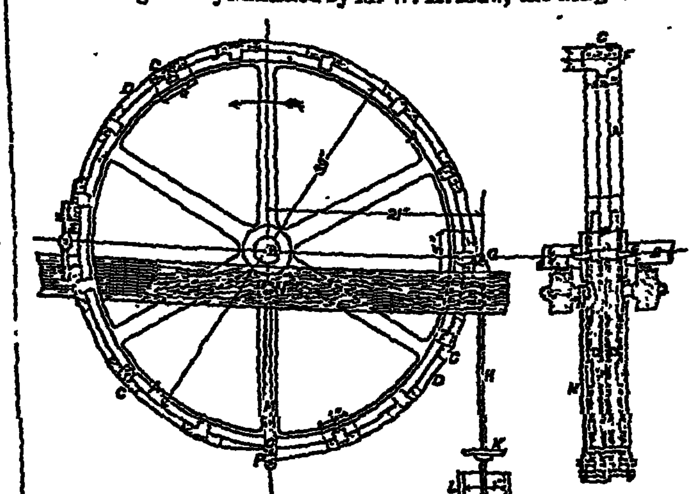

Fig. 2. Fig. 3.

FIGS. 2 and 3.—12 H.P. Friction Brake (designed by W. H. Maw).

drum A has a turned cylindrical surface 39 inches in diameter and 3½ inches wide; it is fixed upon the shaft B with which it revolves. The brake-ring consists of fourteen wooden blocks CC, connected

much altered by the architects engaged to carry on the work, and in particular by Michel Angelo. Competent judges are strongly of opinion that Bramante's designs, if carried out, would have had a much greater effect than those which were finally adopted.

Bramante had a great influence in Italy. By his careful study of the ancient forms of art he became the real introducer of the so-called classical style. His own genius was bold and inventive, delighting in mass and breadth, but occasionally failing in the perfection of detail.

BRAMANTINO. See SUARDI.

BRAMBÁNAN, a village in Java, notable for extensive and remarkable ruins of Hindu character. The place lies directly south of the great volcanic cone of Mir-Api (8640 feet) in the territory of the sultan of Yugya-karta (written by the Dutch Djokjo-karta), and 10 miles east of the capital, just on the border of the other native state called Surakarta or Solo.

The remains embrace six groups of temples, besides two buildings intended for residence, perhaps monastic. The most remarkable of the former is that called *Chandi Sewu*, or "The Thousand Pagodas." The centre of the group is a large temple of cruciform plan, standing on a terraced basement, and surrounded by four (originally, perhaps, by five) concentric squares, formed by rows of small detached cells or temples, the whole area forming a square of upwards of 500 feet to the side. Statements differ as to the exact number of these cells, but a plan given by Raffles shows 238 as now standing. They are sculptured externally with mythological reliefs, each is crowned with a small *dagoba* of the usual Buddhistic pattern (*i.e.*, very like the minor domes over the west portico of St Paul's), and probably all originally contained images of Buddha in the usual cross-legged attitude (of which a few still remain), whilst the central shrine contained, no doubt, a great image or images of Buddha also. Mr Fergusson thinks the group to be Jaina rather than Buddhist; and this a closer examination of the images and their symbols alone can decide. But similar series of shrines, clustered round a central pagoda, are found in Buddhist Pegu. There is a professed restoration of the central temple of Chandi Sewu in Raffles's *History*; but the details of this plate (pl. 40) are not to be relied on.

Another Buddhist edifice, single but more perfect, is known by the name of Chandi Kali Baneng. This also is cruciform; it stands on a boldly moulded basement, and the external decoration exhibits pilasters richly carved in scroll-work, and massive double cornices. Small Buddhas in niches remain, but the great figure which must have occupied the interior has disappeared.

A third group of temples, once, probably, the most important, is known as *Lara Jongran*. These are so ruined that at a short distance they present the aspect of vast and shapeless cairns of stone. One of them contains in three upper cells fine figures of purely Hindu and Brahmanical character. To the north is Durga (here in the character of a strong but beneficent power) slaying the demon Mahishásura,—precisely the same subject that is to be found in Moor's *Hindu Pantheon*, pl. 35. This is the *Lara* or Virgin, who gives the popular name to the group of temples. To the west is the elephant-headed Ganesha, and to the south a fine Jove-like Siva, bearded and trident-bearing. Offerings are sometimes made to these images by the peasantry, in spite of the universal Mahometan profession.

The name of the place is said by Friedrich to be properly *Parambánan*, and to mean probably "the Place of Teachers." The whole of the temples are alleged, in traditional rhymes, to have been erected between 1266 and 1296 A.D. But the chronology and history of the older Javanese remains is still very obscure, and probably the date of some of the Brambánan temples must be carried much farther back. The destruction of the last-described group must have been the work of earthquake, and we must suppose the date of the other buildings to be subsequent to the destruction. Some general points worthy of note in regard to these buildings are the following:—

(1.) They are all built of hewn stones without the use of any cement.

(2.) There are distinct traces showing that the exterior and interior of the buildings were once covered with a fine coat of stucco, not excepting the most elaborate sculpture in scroll-work, &c. We know that the sculptured cave-walls of Ellora, the great idols at Bamian, and the Doric order at Selinus were similarly coated; and probably in all these cases the stucco was intended to bear colour or gilding.

(3.) No real arch exists in these buildings. The vaults and doorways are covered by the corbelling, or stepped projection, of the horizontal courses. Mr Crawfurd makes a contrary statement, but that historian, usually so trustworthy, was certainly mistaken on this point.

(4.) Many of the peculiarities of this architecture, both in general plan and in ornamental details, indicate a close relation to the mediæval styles of Burmah and Camboja; and points almost necessarily to an original common type in India, a type which as yet we cannot trace satisfactorily. In this lies a problem of interest, which the accumulation of photographs will perhaps allow of being worked out. It is notable, however, that in the Burmese mediæval brick buildings of analogous character the true arch is used profusely.—(*Chiefly from the notes of a visit to Brambánan by the writer.*) (H. Y.)

BRANDE, WILLIAM THOMAS, chemist, was born at London in 1788. After leaving Westminster school he spent some time on the Continent, and acquired a knowledge of French and German. On his return he began the study of medicine, and in 1806 a communication of his to the Royal Society was printed in their *Transactions*. In 1809 he was made a fellow of the Royal Society, and became assistant to Sir Humphrey Davy at the Royal Institution. He succeeded Davy in the chair of chemistry in 1813, and in the same year received the Copley medal of the Royal Society. From 1816 to 1836 he was joint editor with Faraday of the *Quarterly Journal of Science and Art*. In 1825 he was made superintendent of the die department in the Mint, and in 1853 he received the honorary degree of D.C.L. of Oxford. He died on the 11th February 1866. Besides numerous papers, which marked him out as one of the most vigorous and able chemists of the day, Brande was the author of several important works. The *Manual of Chemistry*, 1819, and *Elements of Chemistry*, 1831, were the best works of the time, and soon became popular. He also published a *Dictionary of Materia Medica* in 1839, and a *Dictionary of Science, Literature, and Art* in 1842. The latter is an exceedingly able and valuable work of reference; a new edition of it has recently appeared under the editorship of Mr G. W. Cox, 1875. Brande was the author of the third of the Dissertations (that on the progress of Chemical philosophy) prefixed to the supplement of the fourth edition of the *Encyclopædia Britannica*.

BRANDENBURG, one of the largest provinces of Prussia, and the division from which that powerful monarchy originally sprung. It lies between 51° and 53° 34' N. lat. and 11° 25' and 16° 10' E. long., and is bounded on the N. by Mecklenburg and the province of Pomerania, E. by Posen and Silesia, S. by Silesia and the kingdom and province of Saxony, and W. by Anhalt and the provinces of Saxony and Hanover. It has an area of 15,403 square miles, and is divided into the two governments of Potsdam and Frankfort, the capital, Berlin, forming a separate jurisdiction. The province is a sandy plain, interspersed with numerous fertile districts and considerable stretches of woodland. Its barrenness was formerly much exaggerated, and it was popularly described as the sandbox of the Holy

It was translated into Latin in 1497 by Locher, and soon appeared in almost every European language. Alexander Barclay's *Ship of Fooles* (1509) is a free imitation of the German poem, and an abridged prose translation was published by Watson in 1517.

BRANDY, a spirituous liquor obtained by the distillation of wine, the aroma of which is due to ether and other volatile products. It may be distilled from any wine, but red wines yield a less pure and less aromatic spirit than light coloured varieties. In the departments of Charente and Charente Inférieure a variety of grape is cultivated exclusively for the production of brandy, the yield of which constitutes the cognac of commerce. In portions of the departments of the Landes, Gers, and Lot et Garonne, the preparation of brandy is also an important industry, and the produce is commercially known as armagnac, from the name of the district. The cognac district which produces the most rich and delicate spirit distilled is separated into distinct zones of production, according to the quality of the spirit each yields. In the centre of the district on the left bank of the Charente is the *Grande Champagne*, and radiating beyond it are the *Petite Champagne*, the *Premiers Bois*, and the *Seconds Bois* successively. The *Grande Champagne* is the source of the finest brandy anywhere produced; and as the area of cultivation recedes from that centre, the quality of the spirit proportionately lessens. The quantity of brandy exported in 1868 from Tonnay Charente was 9,187,416 gallons, valued at £1,887,678, the greater part of which was consigned to British ports; but the exports fluctuate greatly according to the character of the years. Thus in 1872 the total imports to Great Britain were only 3,505,295 gallons, while in 1873 the quantity was 6,483,486 gallons, of which 6,378,398 gallons came from France. By storage in oak casks the spirit takes up a portion of tannin, which gives it a delicate golden hue, but the deeper colour of brown brandy is communicated by caramel. Cognac is kept in carefully ventilated stores for two years, during which time it decreases in bulk and strength by evaporation, but mellows and develops aroma which continues to increase the longer it is kept. Brandy is very popular as a medicinal stimulant, and for use in cases of sickness, diarrhœa, and spasms. It is very often adulterated, and a vast amount of spirit which passes under the name is really either beetroot spirit or grain whisky coloured and aromatized with the cognac-flavoured œnanthic ether or Hungarian oil. See DISTILLATION.

BRANTFORD, a town of the Dominion of Canada, in the province of Ontario, capital of the county of Brant, is situated on the Grand River, about 24 miles south-west of Hamilton. It is an important station on the Goderich and Buffalo line, with extensive engine-works and foundries. Brass, iron, and tin wares, agricultural implements, window blinds, and pottery are its principal manufactures. It is lighted with gas, and has a good supply of water. As the river is not navigable as far as the town, a canal has been constructed which gives communication with Lake Erie. There are fine county buildings, ten churches, an orphanage, banks, and newspaper offices. Population in 1871, 8107.

BRANTÔME, PIERRE DE BOURDEILLES, SEIGNEUR DE, French historian and biographer, was born about 1540. He was the third son of the Viscount de Bourdeilles, and at an early age entered the profession of arms. He approved himself a brave soldier, and was brought into contact with most of the great leaders who were seeking fame or fortune in the wars that then distracted the Continent. Soon after the death of Charles IX. he retired from active life, and spent his last years in writing his *Memoirs* of the illustrious men and women whom he had known. He died on the 15th July 1614. He left distinct orders that his manuscript works should be printed, and a first edition appeared in 1665-6, not very complete. Of the later editions, the most valuable are—one in 15 volumes, 1740; another in 8 vols., 1787; one in 2 vols., 1842, by Buchon; that of the *Bibliothèque Elzévirienne* in 3 vols., 1858-9; and Lalanne's edition for the Société de l'Histoire de France, 6 vols., 1865, *seq.* Brantôme can hardly be regarded as a historian proper, and his *Memoirs* cannot be accepted as a very trustworthy source of information. But he writes in a quaint conversational way, pouring forth his thoughts, observations, or facts without order or system, and with the greatest frankness and naïveté. His works certainly gave an admirable picture of the general court-life of the time, with its unblushing and undisguised profligacy. There is not an *homme illustre* or a *dame galante* in all his gallery of portraits who is not stained with vice; and yet the whole is narrated with the most complete unconsciousness that there is anything objectionable in their conduct. There does not appear to be any English translation of Brantôme.

BRASIDAS, one of the most famous of the Spartan leaders in the early part of the Peloponnesian War, first distinguished himself by the relief of Methone, which was besieged by the Athenians (431 B.C.) For this service he was publicly commended at Sparta. In 429 he was sent to assist Cnemus, and appears to have taken part in the unsuccessful attack on the Piræeus. Two years later he accompanied the admiral Alcidas to Corcyra, but did not succeed in inducing his superior to make an attack on the city. He was severely wounded in the assault on Pylos (425), and lost his shield, which was picked up and carried in their triumph by the Athenians. When it was resolved by Sparta to carry the war into Thrace, Brasidas was selected as leader. He relieved Megara in 424, and in the same year succeeded in passing through Thessaly and in effecting a junction with Perdiccas of Macedon. He assisted Perdiccas to put down a revolted vassal, Arrhibæus, and then, in an extremely short time, partly by his skilful policy, partly by the rapidity and boldness of his movements, succeeded in gaining possession of Acanthus, Stagira, Amphipolis, and Torone. In the spring of 423 a truce was agreed upon; but Brasidas insisted upon retaining Scione, which had capitulated a day or two after the truce began; this was denied, however, by the Spartan general. The revolt of Mende gave him another opportunity, and he seized that town. Later in the same year he again accompanied Perdiccas against Arrhibæus, and made a most skilful retreat. He received no reinforcements from Sparta, where the leaders seemed jealous of his success, his conciliatory manners, and his dexterous policy. The Athenians, on the other hand, sent out a new armament, retook Mende, and repelled an assault on Potidæa. In 422 Cleon with the fresh Athenian troops besieged Amphipolis. A swift sally, directed by the skilful generalship of the Spartan leader, was crowned with success. The Athenians were routed, and Cleon slain, but Brasidas himself was mortally wounded. He was interred at Amphipolis, the inhabitants making him the founder of their city, and instituting yearly sacrifices and games to his memory. *Brasideia* were also celebrated to his honour in his native city, none but pure Spartans being allowed to join in the games. Brasidas is the only Spartan general whose character displays nobility or grandeur. He had to some extent thrown off the mental stiffness produced by the rigid oligarchical institutions of his native city. He could make himself popular with the allies, and the charm of his personal character secured for Lacedæmon many a city which would not otherwise have joined the league. Thucydides gives him great praise, describes him as being eloquent for a Spartan, and mentions his reputation for justice, liberality, and wisdom. Brasidas was indeed the

zinc, and as this alloy can be rolled out hot it is much more cheaply and expeditiously prepared than ordinary sheet brass.

Wire Drawing.—Brass wire is consumed in enormous quantities, first and chiefly for pin-making, next for shoe-rivets, then for brush-making, for paper-makers' wire web, and many other purposes. The metal for wire drawing is rolled into long strips of a suitable thickness and cut into "strands" by means of slitting rolls. The strands, which are square in section, are drawn through a succession of circular holes in a steel draw-plate, till the desired degree of fineness is reached, and are wound upon a rotating drum or block. The wire has to be repeatedly annealed as it passes through the plates of ever-diminishing gauge.

Stamping.—A large number of useful articles, as well as many ornamental details, which were formerly produced by the process of casting, are now cheaply and expeditiously made by stamping out of sheets of rolled brass. In this way the ornamentation applied to the cheaper kinds of gasaliers, balance-weights, chain-links, &c., are formed, and cornice-pole ornaments and curtain-rings made; and the process is also applied to the making of door and shutter knobs, finger plates, and lamp-burners, and to the striking up of many useful articles, such as basins and other vessels. In the process of stamping, a die, in which the pattern to be formed is sunk, is prepared by the ordinary process of die sinking, and securely fixed to a heavy iron block sunk into the ground. From each side of this block rise two cast-iron guide pillars, which act as guides to the heavy hammer or ram arranged to slide up and down between them. Into this hammer a "force," or exact counterpart of the sunk die, is fitted, so that on the fall of the hammer the force exactly fits into the die. The work of the stamper in raising his hammer is much lightened by passing the lifting belt over a pulley attached to a shaft moved by steam-power. By this arrangement the workman has only to hold his cord sufficiently tight to create the friction between the belt and pulley necessary to raise the weight, and by letting go his hold, the stamp is allowed to fall with its full momentum against the die. In a compound of such hardness and brittleness as brass it is necessary to raise any pattern by repeated strokes, annealing the metal between each separate blow. The number of blows necessary to bring up any pattern depends on the depth and convexity of the die. The "forces," or counterparts of the die, are made of lead, tin, or other soft metal, while for finishing the stamping when the die contains fine details a "force" made of brass is employed. A modification of the steam-hammer has been adapted for use in the process of stamping. Stamped work as compared with castings is deficient in depth and richness, as it is not practicable to attain any great boldness and sharpness of outline, and the "force" having to fit into every portion of the die, no undercutting is possible. Globular articles, such as balance weights, are stamped in two (or if necessary more) parts and the pieces joined by soldering. Mr James Atkins of Birmingham has patented an ingenious method of filling stamped shells, such as balance-weights, with molten iron by simply keeping the shell in water while it is being filled.

tied up with wire at short intervals to keep the edges together in the process of soldering; a mixture of granulated brass and borax is filled into the seam, and the tube is passed slowly through a strong heat in the soldering stove, which melts the granulated brass and so unites the edges. The wires are then cut away, and the superfluous solder filed off, the tube is pickled in sulphuric acid, and again passed through the steel conductor. In the case of tubes which require great accuracy of internal gauge, a mandril or solid cylinder of steel is placed inside the tube before it is finally passed through the tool. The external pressure causes the tube to fit closely to its internal support, and while the outside takes the outline of the steel conductor, the inside is made true to the shape of the mandril. Tubes of any given section are thus formed by the use of mandrils having the outline required. Ornamental patterns are impressed on plain tubes by fitting them on mandrils and passing them through a tool, which consists of a strong iron frame carrying three or more rollers so mounted that the open space between their external edges has the sectional form of the tube to be ornamented. On the external face of these rollers is sunk the design which is to be impressed on the tube, and as it is drawn through them the powerful squeeze they give is sufficient to impress ornaments of considerable depth and boldness. Cased-tubes or rods, that is, tubes or rods of iron cased in brass, were invented in 1803 by Sir Edward Thomason, who thus described his invention:—"In watching the operation of drawing brass and copper tubes upon the mandril, I found it required as much power to slide off the hollow tube from the mandril as was required to draw it on. Reasoning from the adhesion of the brass tube to the steel mandril, I found by experiment that the union of copper and iron or brass and iron could be firmly attached by pressure, and conceived that such an application would be useful for making copper bolts for shipping, solid brass rods for stair carpets, solid brass to go round the top of a room to suspend pictures, as curtain rods for drawing-rooms, and as balustrades for staircases." Wood is cased in brass by a similar process, and used for such purposes as brass cornice-poles. Solid or seamless brass tubes, which are in very extensive demand for locomotive and other steam boilers, are made by drawing down short thick cast cylinders of brass till they reach the desired gauge and thinness. The instrument in which this drawing is accomplished is similar to the apparatus for impressing ornamental patterns on plain brass tubes. Four steel rollers are mounted in a strong frame, the sectional outline of the outer surfaces of which have the size and form to which the tube is to be drawn, and through a series of such tools the cast cylinders are passed, after annealing at each operation. Mr G. F. Muntz in 1852 patented a method of drawing tubes cast in an oval form in the heated state.

Brass Finishing.—The operations in brass finishing comprise "dipping," "burnishing," and "lacquering," and in some cases brass-work is finished by "bronzing." After the article to be finished has been cleaned by pickling in acid, it is passed for dipping into an earthenware jar containing a solution of aquafortis (nitric acid). For bright dipping the acid is used strong, and the brass is immediately withdrawn from the bath, but for "dead" dipping, *i.e.*, for producing a bitten, frosted appearance, the bath is made weaker and the metal left in it till a creamy appearance is seen on the surface. Burnishing is accomplished by rubbing with polished steel tools, called burnishers, the parts of dead dipped work which are to be brightened. The work is then passed through water soured with acid, rinsed, and dried in boxwood sawdust. For lacquering, the work is heated over stoves, and while it is hot, a coating of varnish, made of seed-lac dissolved in spirit, is carefully

undertakings, was born at Baerton, near Chester, November 7, 1805. He was the son of a landed proprietor, of ancient family, and received an ordinary commercial education at a Chester school. He began his professional career at the age of sixteen as apprentice to Mr Lawton, a surveyor, and on the completion of his term became the partner of his master. Soon after his marriage his master died, and he assumed the sole management of the business. In the local surveys to which he devoted his attention during his early years he acquired the knowledge and practical experience which were the necessary foundation of his great reputation. His first engagement as railway contractor was entered upon in 1835, when, on the invitation of the distinguished engineer Joseph Locke, he undertook the execution of a portion of the Grand Junction Railway. Soon after Mr Locke entrusted him with the completion of the London and Southampton Railway, a task which involved contracts to the amount of £4,000,000 sterling and the employment of a body of 3000 men. At the same time he was engaged on portions of several other lines in the north of England and in Scotland. In conjunction with his partner, Mr W. Mackenzie, Brassey undertook, in 1840, the construction of the railway from Paris to Rouen, of which Mr Locke was engineer. He subsequently carried out the extension of the same line. A few years later he was engaged with his partner on five other French lines, and on his own account on the same number of lines in England, Wales, and Scotland. "At this time," says *The Builder*, "the industrial army set in motion and controlled by Mr Brassey amounted to 75,000 men, and his weekly payments must have distributed, as the price of labour, from £15,000 to £20,000 every Saturday. The capital involved in these various contracts amounted to some £36,000,000 sterling." But his energy and capacity were equal to still larger tasks. He undertook in 1851 other works in England and in Scotland; and in the following year he engaged in the construction of railways in Holland, Prussia, Spain, and Italy. One of his vastest undertakings was the Grand Trunk Railway of Canada, 1100 miles in length, with its astonishing bridge over the River St Lawrence. In this work he was associated with Peto and Betts. In the following years divisions of his industrial army were found in almost every country in Europe, in India, in Australia, and in South America. It must be remembered that, besides actual railway works, he originated and maintained a great number of subordinate assistant establishments, coal and iron-works, dockyards, &c., the direction of which alone would be sufficient to strain the energies of a common mind. His profits were, of course, enormous, but prosperity did not intoxicate him; and when heavy losses came, as sometimes they did, he took them bravely and quietly. Among the greatest of his pecuniary disasters were those caused by the fall of the great Barentin viaduct on the Rouen and Havre railway, and by the failure of Peto and Betts. Brassey was one of the first to aim at improving the relations between engineers and contractors, by setting himself against the corrupt practices which were common. He resolutely resisted the "scamping" of work and the bribery of inspectors, and effected what he called the "smothering of the engineer" by destroying the power of the inspectors and preventing all just grounds of dissatisfaction. Large hearted and generous to a rare degree, modest and simple in his taste and manners, he was conscious of his power as a leader in his calling, and knew how to use it wisely and for noble ends Honours came to him unsought. The cross of the Legion of Honour was conferred on him. From Victor Emmanuel he received the cross of the Order of St Maurice and St Lazarus; and from the emperor of Austria the decoration of the Iron Crown, which it is said had not before been given to a foreigner. He died at St Leonards at the age of 65, December 8, 1870. His life and labours are commemorated in a small volume published by Sir Arthur Helps in 1872.

BRAUNSBERG, a town of Prussia, capital of a circle in the government of Königsberg, on the Passaye, between three or four miles from its mouth in the Frische Haff. It is the seat of the Roman Catholic bishop of Ermeland, and possesses numerous Roman Catholic institutions. Of these the most important are the Lyceum Hosianum, founded in 1564 by the Cardinal Bishop Hosius, and in 1818 raised to the rank of a faculty of theology, and the deaf and dumb asylum which was established in 1811. There is also a school for the education of schoolmasters. Brewing, tanning, and weaving are the most important industries of the town, which also carries on a certain amount of trade in corn, ship timber, and yarn. The river is navigable for small vessels. Braunsberg was founded by the Teutonic knights in the middle of the 13th century. Destroyed by the Prussians in 1262 it was restored in 1279, and admitted to the Hanseatic League in 1284. After numerous vicissitudes it fell into the hands of the Poles in 1520, and in 1626 it was captured by Gustavus Adolphus. The Swedes kept possession till 1632. Population in 1871, 10,471.

BRAY, a seaport town and fashionable watering-place of Ireland, 12 miles S.S.E. of Dublin on the railway to Wexford. It is situated on both sides of the River Bray, which separates the two counties of Wicklow and Dublin, the portion in the latter county being known as Little Bray. The town is neatly built, and has a new parish church, a large Roman Catholic chapel, an old castle, a hospital, a court-house, several hotels, and Turkish baths. An esplanade runs along the shore for about a mile. The harbour admits small vessels only, and the trade is of little importance. There is a large brewery, which has been in existence for a considerable time. In the 12th century Bray was bestowed by Strongbow on Walter de Reddesford, who took the title of Baron of Bray, and built a castle in the town. It has since passed into the hands of various families. Its progress during the present century may be estimated by the gradual increase of the population—1841, 3185; 1851, 3156; 1861, 5363; 1871, 6077.

BRAY, Sir Reginald, architect, was the second son of Sir Richard Bray, one of the privy council of Henry VI. Having been instrumental in the advancement of Henry VII. to the throne of England, he was greatly in favour with that prince, who bestowed upon him honours and wealth. His taste and skill in architecture are attested by those two exquisite structures, Henry VII.'s chapel at Westminster and St George's chapel at Windsor. He directed the building of the former, and the finishing and decoration of the latter, to which, moreover, he was a liberal contributor. He died in 1503, and was interred in St George's chapel.

BRAY, Dr Thomas (1656-1730), was born at Marton, in Shropshire, and educated at Oxford. After leaving the university he was appointed vicar of Over-Whitacre, and rector of Sheldon. Bishop Compton sent him as his commissary to settle the affairs of the infant church of Maryland. He took a great interest in colonial missions, and busied himself in raising sums for purchasing small libraries for the use of missionaries; and to promote this design, he published his *Bibliotheca Parochialis*, and a discourse on *Apostolical Charity*. He endeavoured to establish a fund for the extension of the Christian faith, especially among the American Indians, and it is to his exertions that the Society for the Propagation of the Gospel owes its existence. He was the author of *Catechetical Lectures*, *Martyrology, or Papal Usurpation*, *Directorium Missionarium*, and other works.

ate VII. IN presenting an account of this extensive and important country, the only American monarchy we shall give, *first*, a condensed view of its physical geography, meteorology, and natural products; *secondly*, a brief historical sketch of the progressive discovery of its coasts and interior, of its gradual settlement, and of the auspices under which its social institutions have developed themselves; and *thirdly*, an account of its existing political and social condition.

ound-ies. Brazil is bounded on the N. by Columbia or New Granada, Venezuela, and the Guianas, British, French, and Dutch; on the E. by the Atlantic; on the S. by the republics of Uruguay and the Argentine Confederation; and on the W. by Paraguay, Bolivia, Peru, and Ecuador. It extends from about 4° N. lat. to 33° 41′ S. lat., and from 35° to 70° W. long. Its greatest length is about 2600 British miles, its greatest breadth about 2500; and it has a seaboard of about 4000 miles.

The original line of demarcation between the Portuguese and Spanish possessions was fixed by two bulls of Pope Alexander VI., the one of the 2d, the other of the 3d of May 1493. The kings of Castile and Portugal afterwards concluded the treaty of Torrizillas, which was approved by the Pope in 1529. The reunion of the two crowns in 1580 suspended all discussions about the boundaries. They, however, recommenced after the revolution and independence of Portugal. The treaty of Utrecht in 1777 regulated many points, but the treaties always referred to rivers, mountains, and other positions passing through deserts, the names of which were not well established. For sometime past the Government of Brazil has taken great pains to establish amicably with the neighbouring states the boundary lines of the empire. In 1851 these were established with the republic of Uruguay, in 1857 with the Argentine Republic, in 1858 with Peru, in 1859 with Venezuela, in 1867 with Bolivia, and in 1872 with Paraguay; the lines determined on have in some cases been already surveyed and marked out on the actual frontier, while at present mixed commissions from Brazil and each neighbouring country are employed in tracing out the other lines agreed upon.

With Uruguay the frontier has been marked out along a line passing from the coast in 33° 41′ S. lat., through the southern portion of Lake Mirim and along the River Jaguarão, which falls into it, to its most southerly source stream, thence by a line crossing the head of the Rio Negro to the dividing ridge called the Cuchilla Sta. Anna, and afterwards down the stream of the Cuarein or Quarahim to the River Uruguay.

The Uruguay River, from the mouth of the Quarahim upwards to the confluence of the Pepiry on its right bank in 27° 10′ lat. divides Brazil from the Argentine Republic, the remainder of the mutual frontier of these countries being formed by the Pepiry to its source and the São Antonio from its rise to its union with the Y-Guasú or Curityba, which river marks the boundary to the Paraná.

Between Paraguay and Brazil the frontier runs from the mouth of the Y-Guasú up the Alto Paraná to the great fall of Guayrá, called Sete Quedas by the Brazilians, and from that westward along the water-parting of the Cordillera of Maracajú, southward of the basin of the Igatimi, to the heights of Amambahý, and along these to the source of the Rio Apa-Estrella, following it down hence to the Paraguay.

With Bolivia the boundary lies along the Rio Paraguay from the mouth of the Apa in 22°, upwards to 20° 11′, where the Bahia Negra joins it; along the Bahia Negra, and thence in a line to the lake of Cáceres, cutting through the midst of this lagoon, and passing onward to Lakes Mandioré, Gaiba, and Uberaba, and from the last to the south end of the ridge called Corixa Grande; from this in a direct line to Morro de Buenavista (Boavista), and to the sources of the Rio Verde; along the middle of that stream to its mouth in the Guapore, and along that river and the Mamore to the Beni, where the Madeira begins in 10° 20′ S.; a direct line thence to the source of the Yavari River (found by Chandless in 1867 to be a little south of 7° S. lat.), forms the limit of Brazil with Northern Bolivia and Central Peru. The Yavari continues the boundary between Brazil and Peru down its channel to the confluence with the Amazon at Tabatinga, and the limits commission has been at work during 1874 and 1875 in determining the position of this line. Farther on, the boundary of Brazil with Northern Peru has been described as a line passing northward from Tabatinga towards the mouth of the Rio Apaporis in the River Japura, the frontier with Peru terminating on this line where it intersects the Rio Putumayo, and that with Ecuador beginning there. From the mouth of the Apaporis the continuation of the limit with Columbia or New Granada to that with Venezuela follows a line drawn along the water-parting of the range called the Collina do Guaicia or Serra Aracuara, which divides the streams flowing to the Guainia, or Rio Negro, above the Casiquiáre, from those which join it below the anastomosis of that natural canal. This line meets the Rio Negro about 20 miles below the separation of the Casiquiáre. From the Sierra Cucuhy, or Pão d'Azucar, on the opposite or left bank of the Rio Negro, the limit continues eastward over the level ground to the middle of the natural canal called the Maturacá, which in times of flood unites the Cababoris tributary of the Rio Negro with the Barria, a sub-tributary of the Casiquiáre channel. Hence the limit is drawn from the Maturacá to the hill of Cupi, the first of the long range of Serras which divide the waters flowing to the Amazon from those tributary to the Orinoco, and those passing through British, Dutch, and French Guiana to the Atlantic. This boundary follows the curves of the water-parting eastward along the Serras named Guahy and Ucuruciro; northward on those of Tapirapecó and Parima; eastward again along the Merevary and Pacaraima heights; southward between the rivers Tacutu and Rupununy, and again generally eastward along the Serras of Acarahy and Tucumuraque to the source of the River Oyapok. This river, from its source to the Atlantic in 4° 22′ N. lat., is the present eastward limit of French Guiana. Several islets in the Atlantic belong to Brazil; among them that of Fernando Noronha, 250 miles from Cape S. Roque, high, and having about 6 square miles of area, is important as a penal settlement of the empire.

The immense territory comprised within the line just described and the Atlantic is upwards of 3,288,000 English square miles in area, or not far short of the extent of Europe.

The great river of the lowlands of Brazil, the Amazon, Rivers. has been called the Mediterranean of South America, and is the largest stream of the globe in every respect, affording, with its great tributaries, free navigation over not less than 30,000 miles within Brazilian territory (see AMAZON).

After the Amazon the Tocantins is the great river of the northern watershed of Brazil. Rising in the Serra das Vertentes in Central Brazil, the Araguaya, its longer head stream, and the Tocantins flow northward for 900 miles, separated by the Cordillera Grande of Goyaz, and unite at about 300 miles from their wide estuary, called the Rio Pará, formed between the island of Marajo and the main-

land. Midway in its course the Araguaya forms the remarkable island called the Ilha Bananal or Santa Anna, which is encompassed by branches of the river 220 miles in length, and contains a central lake of 80 miles in extent. The Araguaya is navigable, but the upper Tocantins is barred by falls, and there is a rapid at some distance below their confluence round which a road has been recently made to unite the navigable portions.

The Turyassú, Maranhão, and Paranahyba are the largest of the other rivers of the north-eastern slope. The last named flows for the greater part of its course of 700 miles through level swampy lands, receiving many tributaries from eastward, but few from the west; it is without obstructions, and navigable for a great distance.

The São Francisco occupies a wide enclosed basin of the eastern highland. Rising in the Serra do Espinhaço and the Vertentes of Minas Geraes, it flows north and eastward in a course of 1800 miles. But for a few obstacles the greater part of the river would be navigable, since it has great volume. The chief barrier is in the Falls of Paulo Affonso, about 168 miles from the sea, where the river is contracted between rocks, and plunges in a series of cascades into a narrow rock-impeded channel. Immediately below this, however, it spreads out as a broad calm river, which is regularly navigated by steamers from the Porto das Piranhas to the sea.

Among the rivers of the coast slope south of the São Francisco the chief are the Paraguasú, the largest stream of the province of Bahia, obstructed by many falls; the Rio de Contas or Jussiapé, a considerable river in the south of the province, also innavigable; the Belmonte or Jequitinhonha from the high mountains of Minas Geraes, interrupted by many rapids and cascades, and forming a series of magnificent falls over the eastern edge of the plateau, in which it descends at least 300 feet; the Rio Doce or Chopotó in the province of Espiritu Santo, affording a considerable length of navigation, with portages at its reefs; and the Parahyba do Sul, flowing between the Serra da Mantiqueira and the coast range of Rio de Janeiro, navigated regularly by steamers from its mouth for 60 miles to São Fidelio. Though these coast streams are among the little rivers of Brazil, every one of them is two or three times the length of the Thames.

The great rivers of the southern watershed are the Paraná and Paraguay. The former has its rise in a broad basin, extending for a width of nearly 700 miles across southern Brazil, enclosed by the coast range of the south, the Serra da Mantiqueira, the Vertentes, and its southward interior branch running down into Paraguay. The main and longest head stream of the Paraná is called the Rio Grande or Pará, which rises in the Serra da Mantiqueira, one of its sources being on the slope of Itatiaiossú, the highest point of the whole empire, 110 miles north-west of Rio de Janeiro. The Paranahyba joins the Grande on the right from the Pireneos range in the north, and further on the Paraná-Panema, with its tributary the Tibagy, comes in on the left bank from the inner slopes of the south coast range; the Rio Pardo, Ivinhima, and Igatimi are smaller tributaries on the left bank from the interior ranges. After the confluence of the Grande and Paranahyba the Paraná takes its proper name and flows southward out of Brazil in forming the limit between the empire and the republic of Paraguay. The fall of Urubupunga, 40 miles below the confluence of the Grande and Paranahyba, is an obstacle to the navigation of the upper river; but thence to the great "salto" of Guayrá on the frontier of Paraguay, in 24° S., it is freely navigable. The fall of Guayrá, Sete-quedas, or Seven Falls, is the greatest cataract of Brazil. Immediately above it and below the large island which the Paraná forms between 23° and 24° the river is about 2½ miles in width; its channel is contracted first in passing through a diagonal line of seven islands which stretches across it, and then between the walls of a rocky gorge only 65 yards in breadth, into which the whole mass of water plunges with terrific fury, descending over a slope inclined about 50°, and for a perpendicular height of about 60 feet. The roaring of the cataract may be heard for many leagues round. Below the fall, the river rushes down in a narrow bed with high cliff-like banks, only becoming less rapid and navigable with difficulty as it leaves the Brazilian frontier at the confluence of the Y-Guasú. This tributary, also named the Curityba, has a westward course to the Paraná, from many heads in the inner side of the south coast range, and like all the tributaries of the Paraná between it and the great fall, descends into the deep gorge of the main river by a fine waterfall of 66 feet.

The River Paraguay, the upper basin of which lies in a much lower region of the continent, in the south-western interior of Brazil, is far superior to the Paraná in respect of its navigable qualities, and in the grand natural outlet it affords to the southward. Its sources are in several small lakes on the southern slope of the Serra das Vertentes, between 13° and 14° S., immediately opposite the head streams of the Tapajos, and it flows thence southward, fed by many lateral streams from the range. Its important tributary the Cuyabá, or São Lourenço, rises not far east of the Paraguay, but does not join it until both have passed about 400 miles south. The Taquari, the Mondego, and the Apa, the boundary river of Brazil and Paraguay, are important tributaries from the range which divides the basins of the Paraguay and Paraná; and from the hills of eastern Bolivia the San Juan and Bahia Negra join the Paraguay on the right bank. Throughout its course the Paraguay affords uninterrupted navigation, and is regularly traversed by large Brazilian steamers from the Rio de la Plata to Curumbá, in the province of Matto Grosso, a distance of about 1000 miles in a direct line from Buenos Ayres. Thence smaller vessels carry on a regular traffic for 300 miles further, by the São Lourenço tributary, to Cuyabá in the very heart of inner Brazil. An immense tract of the low country on each side of the upper Paraguay, called the Xarayes, between 17° and 19° lat., is subject to inundation in times of flood.

While the Amazon begins to rise in February or March, and is at its highest flood in June, the Paraná is irregular in its risings, but has its greatest volume in December, and the Paraguay again, regularly swelling and falling, is highest in June.

The surface of Brazil in respect to its elevation is divided into the *higher region* of plateaus, ridges, and broad open valleys, occupying the whole of the country south of the parallel of Cape S. Roque, and the vast *lowland plain* of the Amazon, extending inland to the base of the Andes of Peru, Equador, and Columbia, and rising again in the extreme north to the ranges which form the boundary with Venezuela and Guiana. Surface.

The nucleus of the mountains and plateaus of southern Brazil is not centrally placed, but is formed by the chains named the Serra da Mantiqueira and Serra do Espinhaço, which extend between 18° and 23° south lat., at a varying distance of from 100 to 200 miles from the south-east coast. These are the highest and most important mountains of Brazil, from which the other ranges and plateaus radiate outwards north, west, and south; one of the summits of the Serra da Mantiqueira is the Pico do Itatiaiossú, which is almost certainly the culminating point of Brazil, but the elevation of its peak has been very variously estimated and measured at from 6250 to 8900 and 10,300 feet. Itacolumi, near the town of Ouro Preto, reaching about 5700 feet, and Itambe in the north of the Serra do Espinhaço, 4300 Mountains and plateaus.

feet, are the other high points of these ranges. The southern coastal range, or the Serra do Mar, begins immediately north of the Bay of Rio de Janeiro, where the Orãgos or Organ Mountains, with sharp peaks, rise to perhaps 7500 feet, and follows the line of the shore southward at varying distances from it to near the 30th parallel. The line of the Serra do Espinhaço is prolonged northward by another maritime chain or plateau edge, more distant from the ocean, forming the eastern barrier of the great valley of the Rio São Francisco, and terminating where the river turns eastward to reach the sea.

A range of high plateaus, probably from 3000 to 4000 feet in general elevation, and named collectively the Serra das Vertentes, or the range of the watersheds, but bearing a multitude of different names in its local sections and branches, extends westward from the Serra do Espinhaço, nearly at right angles to its direction, traversing the entire country in curving lines inland for upwards of 2000 miles to where the plateaus of Brazil terminate on the great bend, and the cataracts, of the Rio Madeira. This very extensive range divides the waters flowing northward to the lower Amazon and to the Atlantic shores of the north-east, from those tributary to the great basins of the Paraguay and Paraná in the south. Its highest known portion is that called the Montes Pyreneos, between the heads of the Tocantins and Paranahyba in the province of Goyaz, one of the summits of which has been found to be perhaps 9600 feet above the sea (H. R. Dos Genettes, 1868). Long branches ramify northward and southward from the Vertentes; the principal of those trending northward is that which, leaving the main line of division at the Pyreneos, curves round the basin of the São Francisco, terminating in many minor branches on the coast on each side of Cape S. Roque. A lateral branch from this divides the streams of the Tocantins and of the northern Paranahyba. Farther west the Cordillera Grande of Goyaz runs north from the Vertentes, separating the Araguaya and Tocantins, and still more inland minor ranges mark out the basins of the Xingu and Tapajos. A southward arm of the Vertentes, or rather a series of plateaus extending from it, divide the Paraguay from the Alto Paraná, and run into Paraguay as the heights of Amambahý, which have an elevation of little over 2000 feet above the sea where they cross the frontier. These are the main lines of height, but over the whole of the plateau of Southern Brazil a great number of lesser ridges run out from these between each of the tributary river basins.

The extremely level character of the great northern lowlands may be judged of by this, that the banks of the Amazon where it enters Brazil at Tabatinga, more than 1500 miles in a direct line from the sea, are not more than 250 feet above the ocean level, and a continuous navigation is afforded by its tributary the Rio Negro, the Casiquiare, and the Orinoco, to the northern coast of the continent.

logy. The great constituent of all the mountain ranges of the southern highlands of Brazil appears to be gneiss, varying from schistose to coarse-grained and porphyritic, or homogeneous and granitic; and though much of it if seen in a small specimen would be and has been described as granite, the larger masses are always stratified. These rocks are of great thickness in the province of Rio, and the Serra do Mar and Serra da Mantiqueira are wholly composed of them; not only does gniess form the great coast belt from Maranhão to the mouth of the Rio de la Plata, but it sends off a band into Minas Geraes and Goyaz, where the Pyreneos range and a great part of the mountain region are composed of it. The same rock shows itself in the cataracts of the Tocantins, Xingu, Tapajos, and Madeira, as well as in the Parima Mountains north of the Amazon basin, showing that the high land of Brazil is probably everywhere underlaid by it. Clay-slates with auriferous veins occur in Minas Geraes and in the vicinity of Cuyabá in Matto Grosso, everywhere so metamorphosed that all trace of fossils has been obliterated. True Carboniferous strata occur in Brazil, the coal basins lying just south of the tropic, and being a coast-formation not known northward of Rio. Carboniferous rocks also occur on the Guapore, a tributary of the Madeira on the Bolivian frontier. Red sandstones occupy a large area in the province of Sergipe, underlying the Cretaceous formation. The Jurassic rocks, which extend on the Andes from Chili to Peru, appear to be altogether wanting in Brazil. Cretaceous rocks very probably underlie the great plain of the Amazon; they do not appear on the coast south of the Abrolhos rocks in 18° S., but they occur at intervals northward, and have been examined on an affluent of the River Purus in the upper basin of the Amazon. These appear to have been deposited at a period when the northern part of Brazil was more depressed, while the southern may have been higher than it is now. Tertiary clays and ferruginous sandstone, in horizontal and undisturbed beds, overlie the Cretaceous rocks unconformably on the coast plains outside the plateaus and in the São Francisco valley; the horizontal deposits of the plateau of São Paulo evidently belong to the same group.

Surface "drift" deposits, ascribed with the greater amount of probability to the agency of glacial ice, though the hypothesis has been much disputed, occur as a great sheet of pebbles and overlying clay, extending over an immense area of the empire,—over the whole of the provinces south of Rio, over Minas Geraes in the north-eastern coast provinces, and in the valley of the Amazon westward to the confines of Peru; and not only on the hills but over the lower "campos." Deposits of immense boulders of trap and gneiss, evidently the moraines of former local glaciers, were first described by Professor Agassiz, who found them at many points along the coast land.

True coral reefs occur at irregular intervals along the northern Brazilian coast from the Abrolhos islets, which rise on the submerged border of the continent from a less depth than 100 feet, as far as the shores of Maranhão. They lie in patches at short distances from the coast, leaving navigable channels between them and the mainland. Another class of reefs, also termed "recifes," but of totally different origin, are the consolidated stone beaches, such as those seen at Porto Seguro, Bahia, and Pernambuco (where the reef forms the breakwater of the harbour); these are of precisely uniform character, and have been described by Professor Hartt as the consolidated cores of an ancient beach which has been separated from the mainland by the encroachment of the sea. (*Geology and Physical Geography of Brazil*, by Ch. Fred. Hartt, 1870.) The limestones of the upper São Francisco basin have celebrated bone caverns, which have been made a special object of study by the Danish naturalist Lund. In some of these the remains of extinct animals of high antiquity have been found, such as those of the mastodon, glyptodon, mylodon, toxodon, and megatherium; and with these the stone implements and remains of man, so buried with the bones of the extinct fauna as to leave no doubt that man was contemporaneous with them.

No volcanic appearances have been observed in Brazil. Warm springs Warm springs occur in several provinces; those of Itapicurú in the province of Bahia have temperatures varying from 88° to 106° Fahr. and are saline; the hot springs of pure water in Santa Catharina range from 96° to 113° Fahr., and there are a great number of alkaline springs about the district of Santa Cruz, in the province of Goyaz, ranging up to 119° in temperature. Near the village of Caldas in Minas Geraes the hot wells are very voluminous, and their somewhat sulphurous waters have temperatures between

106° and 113° Fahr. These are at an elevation of about 6000 feet above the sea.

INERALS. The metallic and mineral products which occur in the geological formations above described are very various. iamonds. Diamonds were first discovered in the Serra do Espinhaço, in the vicinity of Diamantina, about 300 miles north of Rio, in 1786. In this neighbourhood there are shales, sandstones, and conglomerates; upon the sandstone there is or was a stratum of quartzite, still very distinct in many places, and among the sands created by the disintegration of this rock, diamonds are found. This district is named the *Chapada* of Diamantina, a term applied to small elevated plateaus, usually consisting of horizontal deposits, and separated by deeply eroded valleys. The diamond-producing soil extends along the Serra do Espinhaço as far as the northern borders of the province of Minas, along the valley of the upper Belmonte, and in the interior of the province of Bahia, as well as in the mountains that lie south-west of the sources of the São Francisco. Diamonds of smaller value have also been found in the province of Goyaz (on the Rio Claro); in Matto Grosso, where the valley of the Paraguay about Cuyabá and Diamantino has diamonds in considerable abundance; in Paraná, on the Rio Tibagy, a tributary of the Paraná-Panema; in São Pedro do Rio Grande do Sul; and in São Paulo;—but the area of their distribution is far from being well ascertained. The diamonds are generally obtained by washing; an excavation is made to reach the stratum called *cascalho*, a gravel composed principally of quartz and fragments of different rocks of the neighbourhood, and mixed with a reddish clay. The washers are seated either by a pond or running stream, and a portion of the gravel, being thrown into a large shallow wooden pan, is mixed with water and stirred about in the current, so that the muddy water escapes and the gravel and sand remain. This is now passed through a sieve, which separates the larger gravel from the smaller; the pebbles are then picked out, and the overseer examining the sand easily selects any diamonds that may be present. The diamonds are often of considerable size. Burton mentions one found in the Chapada of Bahia weighing 76½ carats, which when cut into a dropshaped brilliant proved to possess extraordinary play and lustre. Emeralds, sapphires, rubies, topazes, beryls, tourmalines (black, blue, or green), and amethysts are found, especially in the provinces of Minas Geraes. Garnets occur in great profusion, though of inferior quality. Rock crystals, perfectly pure and of large size, are obtained in Minas, Goyaz, São Paulo, and Paraná; opals, chalcedonies, agates, and carnelians are found nearly throughout the country, but have become an article of export chiefly from the banks of the Uruguay, in the province of Rio Grande do Sul.

One of the Brazilian coal basins lies in the province of Santa Catharina, between the plateau and the sea; and along the banks of the Tubarão, beds of bituminous coal of fair quality are exposed, and were first noticed in 1841. Three separate coal-fields have been traced in the province of Rio Grande do Sul: the largest is situated in the valley of the Jaguarão (the boundary river with Uruguay), and in that of the Candiota, covering an area of about 50 miles by 30 miles; the second occurs in the valley of a tributary of the Rio Jacuahy, near the centre of the province; and a third near the village of São Jeronymo, on the bank of the Jacuahy. The Candiota field is now being worked by an English company. At the Arroyo dos Ratos in the same province, mines have been worked on a small scale, the coal from which is used by the steam-boats which ply on the Lagoa dos Patos, or on the rivers. Bitumen is found in most of the provinces, and is worked near the south coast of the province of Bahia.

Sulphur exists in a native state in the province of Rio Grande do Norte, and in small quantity in Rio Grande do Sul, as well as at Furquim and Corrego do Ouro, in the district of Minas Novas in Minas Geraes. Saltpetre occurs with salt over a large area of Minas Geraes and Bahia, but is also abundantly formed in the floors of the calcareous caves of the Rio São Francisco valley from the city of Ouro Preto downwards. Saline efflorescence is observed at innumerable localities in the drier portions of the Brazilian plateau; efflorescences of nearly pure sulphate of magnesia are also to be found in the valley of the Rio das Velhas in the São Francisco basin, and in the province of Ceará, where chloride of sodium also appears. Saltpetre. Salt.

Gold in Brazil is found in quartz veins traversing the old metamorphic rocks, such as clay-slate, mica-slate, or iron schist, in drift gravels and clays, and in alluvial sands and gravels derived from the wear of these. Most gold is afforded by the clay-slates traversed by auriferous quartz lodes, by the rock called Itacolumite (metamorphic rock of Lower Silurian age), and by certain iron ores known as Itabirite and Jacutinga, the latter described by Burton as a substance composed of micaceous iron schist and friable quartz, mixed with specular iron oxide of manganese and fragments of talc. Over a very large area of the province of Minas Geraes, in the vicinity of Ouro Preto, the country is auriferous, and here are the richest gold mines of Brazil. The celebrated Morro Velho mine is situated on the western side of the valley of the Rio das Velhas, not far from Sabará, and was at first worked by native miners, but afterwards with great success by a company. The mines of Gongo Soco lie about 20 miles east of Morro Velho, on the opposite side of the Velhas, and were at one time very productive. Another company owns a tract of 21 square miles, not far from the Morro Velho. Other mines have been worked in this neighbourhood at the Morro de Sta Anna, at Maquiné near it, and in the Serra of Cata Branca, 2 miles east of the village of Corrego Seco. These mines with two exceptions have proved failures in working, after a period of success, and this notoriously from bad management. The mines, however, are very far from being exhausted; indeed the underground wealth of the country is as yet almost untouched. Much of the remaining portion of the province of Minas, and especially the upper basin of the São Francisco, is auriferous. In Northern Brazil the only gold mine yet opened is that of Tury-assú in the province of Maranhão; but concessions for working gold have been granted by Government in many parts of the provinces of Bahia, Pernambuco, Parahyba, Piauhy, Goyaz, Ceará, and S. Paulo. In southern Brazil gold is known at Caçapava, Rio Pardo, Sta. Maria, and Cruz Alta, in the province of Rio Grande do Sul; and at the first-named locality a Brazilian company is carrying on the work of mining. Gold washings occur in almost every province, but especially in the district of Minas Novas, 200 miles north of Ouro Preto, where the metal is found in grains or nuggets in a *cascalho* of quartz pebbles, often cemented into a conglomerate by iron oxide. They are carried on, however, in the rudest and most irregular way, and with more modern appliances might prove very remunerative Gold.

The gold of Brazil is always alloyed with silver, and this metal is present in many of the galenic formations which are known in almost every province, as well as with the copper in the mines of Rio Grande do Sul. At the hill of Araçoiva, in the municipality of Sorocaba in São Paulo, silver was extracted nearly two centuries ago. Rich mines of mercury occur in the province of Paraná not far from the capital. Copper is abundant in the provinces of Matto Grosso, Goyaz, and Minas, near the capital of Bahia, in Maranhão and Ceará, but chiefly in Rio Grande do Sul, where at Santo Antonio das Lavras, in the municipality of Silver. Mercury. Copper.

Caçapava, there are the richest copper mines of Brazil, the mineral from which yields 60 per cent. of pure metal.

ganese. Manganese exists in abundance in the vicinity of Nazareth, at the head of the estuary of the Jaguaripe, nn. adjoining the bay of Bahia. Galena mines are in operation in many parts of the empire; the chief are those of Iporanga, Sorocaba, Iguapé in the province of São Paulo, and those of the Rio Abaeté and Sete Lagôas, the most productive of l. all, in the province of Minas. Lead mines also exist along the whole coastal region from Santa Catharina to Maranhão, those of the hill chain of Ibiapaba on the borders of Ceará and Piauhy being important.

l. Every part of Brazil contains iron, in ore or in other forms, and an almost unlimited quantity appears to exist in the mountains of Minas Geraes. At São João de Ipanéma, in S. Paulo, there are heavy deposits of magnetic iron, which are mined and smelted almost on the spot; and other seams of like character appear in the provinces of Alagôas, Ceará, Rio Grande do Norte, and Parahyba. Some of the Brazilian mines are quite free from pyrites. In 1810 a company of Swedish miners and founders settled at Ipanéma, and erected two small refining furnaces. In 1817 they produced nearly 4000 arrobas of iron, which was manufactured on the spot into horses' shoes, nails, locks, and other articles. There is now a very considerable establishment, at which moulding and refining is carried on, the woods of the neighbourhood furnishing an abundant supply of charcoal. A railway is projected to unite the works with S. Paulo and its port. Not far from these mines there are extensive quarries of marble of valuable sorts.

MATE. A country so extensive as Brazil, and so diversified in its surface, necessarily exhibits a considerable variety of climate. The great northern lowland lying entirely within the tropics has great heat, and its year is divided between the simple wet and dry seasons. The elevation of the central and southern highland of Brazil introduces great variety in the seasons and climates of the intertropical portion of that region; and towards the south beyond the tropic a temperate zone is reached in which four seasons are marked, nfall. though not so distinctly as in central Europe. The whole wide plain of the Amazon basin has its rainy season from January or December till May or June, the remaining half of the year being dry, though intervals of fine weather may occur within the wet period, and of showers in the dry season. The fall during the rainy months is excessive, raising the level of the great river full 40 feet, and much thunder and lightning always accompanies the heavy rain. This belt of single rainy and dry season appears to terminate about the line of the River Paranahyba, between the provinces of Maranhão and Piauhy; at the town of Maranhão the annual fall has been found to be on an average 280 inches. Inland, across the higher southern watershed of the Amazon, from the interior of the provinces of Maranhão and Piauhy, over Goyaz and northern Matto Grosso as far as the falls of the Madeira, the rainy seasons follow the passage of the sun towards and away from the southern tropic, and occur from October or November to March or April, with more or less marked intervals of drier weather.

In lower Maranhão showers also occur in October, and are called the 'Cashew rains.' On the north-east coast slope, in the provinces of Ceará, Rio Grande do Norte, and northern Bahia, the rains appear to be governed by the prevalence of the north-east winds from the Atlantic, and occur from March or April to June, July, or August. The coastal region from southern Bahia to São Paulo and the São Francisco valley have again a more or less marked double rainy season between October and April or May; the heaviest rains occur in the São Francisco valley from January to May, the highest freshets of the river being in March; the coast rivers, such as the Rio Doce, rise first in December, and again to an almost equal swelling in March. At Pernambuco the amount of the annual rainfall is upwards of 100 inches; at Rio de Janeiro it has decreased to 59 inches, and a gradual diminution of the quantity is observed from the Amazon southward. In São Paulo the rainy season is, in summer, from November till April, the greatest quantity of rain falling in January. In Sta. Catharina the rains begin to be irregular, and from this to the southward over Rio Grande do Sul the four seasons of the temperate zone begin to be distinguishable. The whole country is, as a rule, abundantly watered, the only portion which may suffer from drought being that of the interior between the São Francisco and the Paranahyba, where extraordinary dryness has sometimes prevailed.

In temperature the vast Amazon basin is remarkable for Temperature. the small seasonal variation of heat, accounted for by its equatorial position and immense surface of water and forest; within its limits the thermometer at its highest readings averages 90° and the lowest 75°. At Pará the register kept by Costa Azevedo between 1861 and 1867 gave a mean temperature of 80°, a maximum of 95°, and a minimum of 68°. Observations are very deficient for the greater portion of the empire. About the Falls of the Madeira, Keller estimates the mean annual temperature at 77°, with but small variation in the seasons. In the latitude of Rio de Janeiro the summer or January temperature near the sea-level has an average of about 75°, that of July descending to about 65°; and in the extreme southern provinces the corresponding figures may fall to 70° and 50° Fahr. in summer and winter. But an immense variety of temperature and climatic condition are found on the central and southern table-lands and mountain ranges of Brazil, from the hot and humid air of the coast to the mountains where in winter it frequently snows, and where lakes may be covered with a coating of ice. In the high plains of Rio Grande and São Paulo the thermometer may also fall to below the freezing point.

The prevalent winds of the greater portion of Brazil are Winds. the trade-winds from the east, which, gathering the vapours from the whole breadth of the equatorial Atlantic, give out their excessive moisture over the northern forest plains of the Amazon, reaching inland as far as the high wall of the Andes. The east winds are strongest in the Amazon valley from July till November, mitigating the heat of the dry season. On the maritime regions of central Brazil the north-east or south-east trades prevail according to season. In the far interior the general winds take a more north and south direction, blowing usually from the south when the sun is in the northern tropic and from the north during summer. Land and sea breezes are very constant along the coasts. At the mouth of the São Francisco, for example, the morning is still and calm; about nine o'clock a breeze steals over the water, rippling its surface and gradually increasing to a stiff wind about noon; the breeze continues steadily till night-fall, when it again falls calm.

With the exception of the marshy banks of some of the Health. rivers and the lowlands and swamps, where intermittent fevers are very prevalent, the country is generally healthy. On the sea-coast and inland in some of the maritime provinces, epidemics of yellow fever and cholera morbus have been experienced since 1850. The mortality in the most populous towns of Brazil is not, however, above but rather below that of the large cities of Europe.

The broadly-marked features given to the landscape by VEGETATION. the vegetations of different characters in Brazil are distinguished by several names. *Mattas* or heavy forests cover the immense northern lowland which is watered by excessive rains, and these occur also in belts of greater or less width over the lower portions of the central and southern

region. *Catinga* is the general name applied to the lower growing and open woods of the slopes of the Brazilian highland which lose their leaves in the dry season. These merge into the wide open plains or gently rounded hills and ridges, covered with grass or scattered bushes, which are called the *Campos geraes*. The systematic burning over of these great grass lands, to allow the young crop to appear, has completely destroyed in them all trees and shrubs which cannot bear the scorching, and so has wrought a great alteration in the flora of these regions. The name *Sertão*, meaning originally the interior as distinguished from the maritime country, has come to be applied to dry, hilly, and stony districts of the campos only suited for pasture. To the agricultural coast belt of the eastern provinces the name *Beira mar* is given.

Except on the loftiest mountains, and on the wide *sertãos*, the vegetation of Brazil is luxuriant beyond description. In the mountain passes in the neighbourhood of the sea-shore, the conjoint effects of heat and moisture produce a superfluity of vegetable life, which man's utmost efforts cannot restrain. Trees split for paling in the neighbourhood of Rio Janeiro send forth shoots and branches immediately, and this whether the position of the fragments be that in which they originally grew, or inverted. On the banks of the Amazons the loftiest trees destroy each other by their proximity, and are bound together by rich and multiform lianes. In the province of Maranhão, the roots, grasses, and other plants extending from the shores of pools, weave themselves in time into a kind of vegetable bridge, along which the passenger treads, unaware that he has left the firm earth, until the jaws of a cayman protrude through the herbage before him. The vegetable productions of Brazil have a strong analogy with those of Guiana. The most common are the *Compositæ*, *Leguminosæ*, *Euphorbiaceæ*, *Rubiaceæ*, *Aroideæ*, and ferns of the most varied forms. The vegetation of the valleys differs from that of the *campos*, as it again does from that which occurs in the *sertãos*. Along the coast, the mangroves are the most numerous and prominent species. The most marked peculiarity of this class of plants is, that the seeds begin to shoot before they drop from the parent plant, and that the drooping branches strike roots into the soil. They are never found inland except where the surface is scarcely elevated above the level of the sea. They flourish from Rio Grande do Sul to Maranhão, converting the land into a morass wherever they are allowed to flourish unmolested. Immediately behind them numerous families of palms raise their graceful heads. The underwood in the neighbourhood of Rio Janeiro consists principally of crotons. Every large river of Brazil has its own appropriate form of vegetable life, giving a peculiar character to its banks. The vegetation of the Amazon may be divided into three classes;—(1) that which we find on the islands, (2) the vegetation upon the banks overflowed at regular intervals by the stream, and (3) that which stands high and dry. The difference between them consists in the character of the bark and the species of the plants. Brushwood and herbage are nowhere to be seen; everything tends to the gigantic in size. The most various forms group awkwardly together, crossed and intertwined with leaves. The preponderance of trees with feathery foliage, and with glossy, fleshy leaves, lends alternately a tender and a luxuriant character to the scene, which is in every other respect painful from its monotony. Representatives of the most estranged natural families grow side by side. It is only on the islands, where the willow and some other plants are found in numbers, that we are reminded of the uniformity of our northern vegetation. Cocoa trees and the vanilla, *Capsicum frutescens*, and different kinds of pepper, the cinnamon tree, and Brazilian cassia abound. The flora of all the tributaries of the Amazon is similar to what we have described, until the traveller ascends above the falls, and finds himself in another region. The sources of the Madeira alone offer a partial exception, retaining a vegetation indicative of extensive plains, lakes, and morasses. The vegetation of the southern *campos* (corresponding to the North American *prairies*) is widely different. On the plains of the southern provinces we find scattered about strong tufts of greyish-green and hairy grasses, springing from the red clay. Mingled with these are numerous herbaceous flowers, of the most varied colours and elegant forms. At intervals small groves of trees, seldom exceeding 20 feet in height, so distant that the individual form of each is easily recognized, with spreading fantastic branches and pale green leaves, break the monotony of the scene. Solitary myrtles, numerous varieties of pleasing fruits, and now and then a cactus, add to the variety. A similar vegetation, but with a richer variety of plants, occurs in the diamond district. On the western declivity of the Serra do Mar, and along the upper banks of the Rio São Francisco, extends a wooded "catinga" country, of a character entirely different from that which is found in the valleys below. *Malvæ*, *Euphorbiaceæ*, *Mimosæ*, and the like, are the prevailing types on the Rio Francisco; cactuses, palms, and ferns abound on the Serra do Mar. In this latter district the ipecacuanha flourishes best. It is, however, in the glowing steppes of Pernambuco that we find the cactus predominant. In the valley of the Paraguay the most striking feature is presented by the water plants, which in one river are sufficiently strong to impede the navigation of a stream both deep and broad.

The forests of Brazil contain almost every species of useful and ornamental wood. The cocoa-tree is found in great quantities in the provinces on the sea-shore, and furnishes one of the most important items of internal commerce. A considerable surplus of cocoa is annually exported. One of the most valuable sorts of timber is furnished by the Ibiripitanga or Brazil-wood (*Cæsalpinia brasiliensis*), which yields a fine red dye. The wood itself is very hard and heavy, and takes a beautiful polish. It grew at one time in great abundance along the coast; but being a Government monopoly (thence called *pao da rainho*, Queen's wood), it was cut down in a reckless manner, and is now by no means so abundant as it once was. The other trees most worthy of mention are the *jaracandá* or rosewood tree, the trumpet-tree (*Secropia peltata*), the laurel, the soap-tree, the tapia or garlic pear-tree, and the whole family of palms. Of these the Carnauba Palm (*Copernicia cerifera*), which grows in the north-east coastal province, is perhaps the most useful tree of Brazil; every part of it is valuable, and the wax yielded by its leaves is now a considerable article of trade. Not least important is the *Siphonia elastica*, or caoutchouc tree, which during the season is tapped every day, and furnishes in considerable quantities a gum which is poured into moulds; the export of this product from Brazil averages a value of more than £1,000,000 annually. The banana is one of the most useful of all the trees that grow in Brazil, and its fruit is the chief food of the native Indians. The fruits of Brazil are numerous and excellent. The best of these are the pine-apple, the mango, the custard-apple, the guava, and the various kinds of melons and nuts.

In an empire of such vast extent as Brazil, embracing as it does every variety of temperature and elevation, the value and importance of the agricultural products cannot fail to be very great. So small, however, is the number of farmers, compared with the extent of the soil, that it is believed that not one acre in 200 is under cultivation. In some provinces, especially those near the sea, the quantity of grain raised is not sufficient to supply the

Vegetable products.

demand, and thus large quantities of wheat are annually imported from the United States. The reason of this is that the soil under tillage is occupied in the production of articles for foreign markets. The chief products of Brazil are coffee, sugar, cotton, manioc or cassava flour, tobacco, rice, maize, fruits, and spices. Of these by far the most important now is coffee, while sugar ranks next in value, and cotton after sugar.

ffee. The coffee plant, introduced from Arabia into the French colony of Cayenne in 1722, was soon after brought to Brazil; but it was not until 1810 that Brazilian coffee came to be highly valued in the European markets. In that year, however, Dr Lecesne, a planter, expelled by the revolution from San Domingo, settled near Rio, and introduced the most improved methods of rearing the coffee-plant. So successful has the result of the new system been, that its cultivation now extends from the Amazon to São Paulo; and whereas in 1818 the annual exports of coffee did not amount in value to £240,000, in 1873 the exports were worth nearly £13,000,000.

igar. The cultivation of sugar has not increased nearly in the same proportion as that of coffee, and in recent years a disease of the cane has affected the cultivation seriously. It is produced in greatest quantity in the districts adjoining Bahia. The quantity of sugar exported in 1850 was 16,200 bales, representing a value of about £1,700,000; in 1873 the value of the exports was £3,120,000.

tton. Cotton is found to thrive best in the dry table-lands of the northern provinces, especially in Maranhão and Pernambuco. Its quality is considered excellent; but the rude and expensive method of its culture, and the high rates of carriage in these inland districts, operate very unfavourably for this branch of traffic. The annual value of cotton exported is not much above £3,000,000.

her products. The *Ilex curitibensis*, and other varieties of the holly, which yields the yerba maté, or Paraguay tea, are indigenous to the southern provinces of Rio Grande, Santa Catharina, and Paraná Some attempts have been made towards the cultivation of this product, but the greater part of the tea is rudely made from the tree in its wild state in the woods. The amount annually exported to the River Plate averages between £300,000 to £400,000 in value. Tobacco is chiefly cultivated in the provinces of Bahia, Minas, S. Paulo, and Pará, and in some localities of Rio de Janeiro. Though it is inferior in quality to that of the West Indies, it is exported to the value of between £700,000 and £800,000 annually. The cultivation of cocoa, hitherto obtained from the valleys of the Amazon and Tocantins, is increasing in the provinces of Bahia and Ceará. Rice grows in considerable quantities, and not being much used by the natives for food, a large surplus remains for exportation. The cassava or manioc is extensively grown and forms the staple food of the lower classes The root, which is the part of the plant used for this purpose, contains a deadly poison. It is easily expelled, however, by the action of fire, and the residuum is ground into a wholesome and nutritious flour or farina Tapioca, which is extensively used in Europe, is a preparation of the starch from the root of the cassava.

imals. The varieties of animated life in Brazil are more numerous perhaps than in any other region in the world. Of beasts of prey, the most formidable are the jaguar or South American tiger, the ocelot, the tiger-cat, the puma, the guará or red wolf, and the Brazilian fox or wild dog. Large herds of the peccary roam in the forests, in which also is to be found the tapir or *anta*, the largest South American mammal. The *capivara*, or water hog, abundant on the river banks, is the largest known rodent. Diverse species of deer inhabit the campos; representing the Edentata there are several species of armadillos and ant-eaters, and the sloths; and of the Marsupialia, several species of opossum occurring over the whole of Brazil. The varieties of the monkey tribe that abound in the forests appear to be almost infinite. The largest belong to the genus *Stentor*, including the guaribas or howling monkeys. The *Simia jacchus* has never been seen elsewhere. There are several varieties of bats, of which the *Vespertilio leporinus* and the *V. spectrum* are the largest. No less immense is the variety of birds, from the *ouira*, an eagle far larger than our most powerful birds of prey, to the humming-bird, no larger than a bee. The rhea, a species of ostrich, is found in Brazil. The Brazilian birds are celebrated for the beauty of their plumage. "Red, blue, and green parrots," says Malte-Brun, "frequent the tops of trees. The gallinaceous *jacús*, the *hoccos*, and different kinds of pigeons, haunt the woods. The orioles resort to the orange groves; and their sentinels, stationed at a distance, announce with a screaming noise the approach of man. Chattering manakins mislead the hunter; and the metallic tones of the uraponga resound through the forest like the strokes of a hammer on an anvil. The toucan (*Ramphastos*) is prized for its feathers, which are of a lemon and bright red colour, with transverse stripes reaching to the extremities of the wings. The different species of humming birds are more numerous in Brazil than in any other country of America. One sort is called by the people the *Gnanthe engera* or winged flower." Snakes of every kind abound in the marshy districts, some of which, such as the rattlesnake and the jararaca, are remarkably venomous; while others, such as the boas, attain an enormous size and strength. A vast number of troublesome insects infest the margins of all the great rivers. Of these the most formidable is the *puim*, which is so small as to be scarcely visible, and inflicts a most painful and even dangerous bite. The red ant is peculiarly destructive to vegetation, and whole districts are sometimes laid waste by its ravages. The spider here attains an enormous size, but is not so venomous as might be expected from its appearance. The gayest butterflies flutter through the air,—the blue shining Menelaus, the Adonis, the Nestor, and the Laertes. More than ten species of wild bees have been observed in the woods, and the greater number produce honey. The *Cactus coccinellifer*, and the insect peculiar to it, are found in the province of S. Paulo. Lizards and caymans abound. The quantity of turtle in the Amazon and its principal tributaries is almost incredible. The waters swarm with fish in thousands of species, many of which have not yet been described. Among the largest is the *Pira rucú*, the principal food of large numbers of the people of Pará and Amazonas. Of domestic animals, the most important are the horse, the ox, and the sheep. Vast numbers of horses, sprung from the original European stock, roam at large over the extensive plains of the southern provinces. They are generally found in droves of twenty or thirty. Oxen are also allowed to wander half wild. They are hunted down with the *lasso* in great numbers, and are valued chiefly on account of their hides, horns, and tallow, which are exported in immense quantities. The chief cattle-breeding districts of Brazil are the island of Marajo in Pará, Goyaz, Matto Grosso, Piauhy, S. Paulo, Minas, Paraná, and Rio Grande do Sul. Sheep do not thrive in Brazil at all so well as the larger kinds of cattle.

History. Brazil was discovered in 1499 by Vincent Yañez Pinçon, a companion of Columbus. He descried the land near Cape St Augustinê, and sailed along the coast as far as the River Amazon, whence he proceeded to the mouth of the Orinoco. He made no settlement, but took possession of the country in the name of the Spanish Government, and carried home, as specimens of its natural productions, some drugs, gems, and Brazil-wood. Next year the Portuguese commander, Pedro Alvarez Cabral,

appointed by his monarch to follow the course of Vasco de Gama in the East, was driven by adverse winds so far from his track, that he reached the Brazilian coast, April 24, and anchored in Porto Seguro (16° S. lat.) on Good Friday. On Easter day an altar was erected, mass celebrated in presence of the natives, the country declared an apanage of Portugal, and a stone cross erected in commemoration of the event. Cabral despatched a small vessel to Lisbon to announce his discovery, and, without forming any settlement, proceeded to India on the 3d of May. On the arrival of the news in Portugal, Emanuel invited Amerigo Vespucci to enter his service, and despatched him with three vessels to explore the country. This navigator's first voyage was unsuccessful; but in a second he discovered a safe port, the site of which is not accurately known, to which he gave the name of All-Saints. He remained there five months, and maintained a friendly intercourse with the natives. Some of the party travelled forty leagues into the interior. Vespucci erected a small fort, and leaving twelve men, with guns and provisions, to garrison it, embarked for Portugal, having loaded his two ships with Brazil-wood, monkeys, and parrots.

The poor and barbarous tribes of Brazil, and their country, the mineral riches of which were not immediately discovered, offered but few attractions to a Government into the coffers of which the wealth of India and Africa was flowing. Vespucci's settlement was neglected. For nearly thirty years the kings of Portugal paid no further attention to their newly-acquired territory than what consisted in combating the attempts of the Spaniards to occupy it, and dispersing the private adventurers from France who sought its shores for the purposes of commerce. The colonization of Brazil was prosecuted, however, by subjects of the Portuguese monarchy, who traded thither chiefly for Brazil-wood. The Government also sought to make criminals of some use to the state, by placing them in a situation where they could do little harm to society, and might help to uphold the dominion of their nation.

The first attempt on the part of a Portuguese monarch to introduce an organized government into his dominions was made by João III. He adopted a plan which had been found to succeed well in Madeira and the Azores,—dividing the country into hereditary captaincies, and granting them to such persons as were willing to undertake their settlement, with unlimited powers of jurisdiction, both civil and criminal. Each captaincy extended along fifty leagues of coast. The boundaries in the interior were undefined. The first settlement made under this new system was that of S. Vincente Piratininga, in the present province of S. Paulo. Martim Affonso de Sousa, having obtained a grant, fitted out a considerable armament, and proceeded to explore the country in person. He began to survey the coast about Rio de Janeiro, to which he gave that name, because he discovered it on the first of January 1531. He proceeded south as far as La Plata, naming the places he surveyed on the way from the days on which the respective discoveries were made. He fixed upon an island, in 24½° S. lat., called by the natives Guaibe, for his settlement. The Goagnazes, or prevailing tribe of Indians in that neighbourhood, as soon as they discovered the intentions of the new comers to fix themselves permanently there, collected for the purpose of expelling them. Fortunately, however, a shipwrecked Portuguese, who had lived many years under the protection of the principal chief, was successful in concluding a treaty of perpetual alliance between his countrymen and the natives. Finding the spot chosen for the new town inconvenient, the colonists removed to the adjoining island of S. Vincente, from which the captaincy derived its name. Cattle and the sugar-cane were at an early period introduced from Madeira, and here the other captaincies supplied themselves with both.

Pero Lopes de Sousa received the grant of a captaincy, and set sail from Portugal at the same time as his brother, the founder of S. Vincente. He chose to have his fifty leagues in two allotments. That to which he gave the name of S. Amaro adjoined S. Vincente, the two towns being only three leagues asunder. The other division lay much nearer to the line between Paraiba and Pernambuco. He experienced considerable difficulty in founding this second colony, from the strenuous opposition of a neighbouring tribe, the Petiguares; but at length he succeeded in clearing his lands of them; and not long afterwards he perished by shipwreck.

Rio de Janeiro was not settled till a later period; and for a considerable time the nearest captaincy to S. Amaro, sailing along the coast northwards, was that of Espiritu Santo. It was founded by Vasco Fernandes Coutinho, who having acquired a large fortune in India, sunk it in this scheme of colonization. He carried with him no less than sixty fidalgos. They named their town by anticipation, Our Lady of the Victory; but it cost them some hard fighting with the Goagnazes to justify the title.

Pedro de Campo Tourinho, a nobleman and excellent navigator, received a grant of the adjoining captaincy of Porto Seguro. This, it will be remembered, is the spot where Cabral first took possession of Brazil. The Tupinoquins at first offered some opposition; but having made peace, they observed it faithfully, notwithstanding that the oppression of the Portuguese obliged them to forsake the country. Sugar-works were established, and considerable quantities of the produce exported to the mother country.

Jorge de Figueiredo, *Escrivam da Fazenda*, was the first donatory of the captaincy of Ilhéos, 140 miles S. of Bahia. His office preventing him from taking possession in person, he deputed the task to Francisco Romeiro, a Castilian. The Tupinoquins, the most tractable of the Brazilian tribes, made peace with the settlers, and the colony was founded without a struggle.

The coast from the Rio S. Francisco to Bahia was granted to Francisco Pereira Coutinho; the bay itself, with all its creeks, was afterwards added to the grant. When Coutinho formed his establishment, where Villa Velha now stands, he found a noble Portuguese living in the neighbourhood who, having been shipwrecked, had, by means of his fire-arms, raised himself to the rank of chief among the natives. He was surrounded by a patriarchal establishment of wives and children; and to him most of the distinguished families of Bahia still trace their lineage. The regard entertained by the natives for Caramuru (signifying *man of fire*) induced them to extend a hospitable welcome to his countrymen, and for a time everything went on well. Coutinho had, however, learned in India to be an oppressor, and the Tupinambas were the fiercest and most powerful of the native tribes. The Portuguese were obliged to abandon their settlement; but several of them returned at a later period, along with Caramuru, and thus a European community was established in the district.

Some time before the period at which these captaincies were established, a factory had been planted at Pernambuco. A ship from Marseilles took it, and left seventy men in it as a garrison; but being captured on her return, and carried into Lisbon, immediate measures were taken for reoccupying the place. The captaincy of Pernambuco was granted to Don Duarte Coelho Pereira as the reward of his services in India. It extended along the coast from the Rio S. Francisco, northward to the Rio de Juraza. Duarte sailed with his wife and children, and many of his kinsmen, to take possession of his new colony, and landed in the port of Pernambuco. To the town which was there founded he gave the name of

Olinda. The Cabetes, who possessed the soil, were fierce and pertinacious; and, assisted by the French, who traded to that coast, Coelho had to gain by inches what was granted him by leagues. The Portuguese managed, however, to beat off their enemies; and, having entered into an alliance with the Tobayanes, followed up their success.

Attempts were made about this time to establish two other captaincies, but without success. Pedro de Goes obtained a grant of the captaincy of Paraiba between those of S. Vincente and Espirito Santo; but his means were too feeble to enable him to make head against the aborigines, and the colony was broken up after a painful struggle of seven years. João de Barros, the historian, obtained the captaincy of Maranhão. For the sake of increasing his capital, he divided his grant with Fernan Alvares de Andrada and Aires da Cunha. They projected a scheme of conquest and colonization upon a large scale. Nine hundred men, of whom one hundred and thirteen were horsemen, embarked in ten ships under the command of Aires da Cunha. But the vessels were wrecked upon some shoals about one hundred leagues to the south of Maranhão; the few survivors, after suffering immense hardships, escaped to the nearest settlements, and the undertaking was abandoned.

By these adventurers the whole line of Brazilian coast, from the mouth of La Plata to the mouth of the Amazon, had become studded at intervals with Portuguese settlements, in all of which law and justice were administered, however inadequately. It is worthy of observation, that Brazil was the first colony founded in America upon an agricultural principle, for until then the precious metals were the exclusive attraction. Sufficient capital was attracted between the year 1531 (in which De Sousa founded the first captaincy) and the year 1548 to render these colonies an object of importance to the mother country. Their organization, however, in regard to their means of defence against both external aggression and internal violence, was extremely defective. Their territories were surrounded and partly occupied by large tribes of savages. Behind them the Spaniards, who had an establishment at Asuncion, had penetrated almost to the sources of the waters of Paraguay, and had succeeded in establishing communication with Peru. Orellana, on the other hand, setting out from Peru, had crossed the mountains and sailed down the Amazon. Nor had the French abandoned their hopes of effecting an establishment on the coast.

The obvious remedy for these evils was to concentrate the executive power, to render the petty chiefs amenable to one tribunal, and to confide the management of the defensive force to one hand. In order to this the powers of the several captains were revoked, whilst their property in their grants was reserved to them. A governor-general was appointed, with full powers, civil and criminal. The judicial and financial functions in each province were vested ı the *Ouvidor*, whose authority in the college of finance as second only to that of the goveɪnor. Every colonist as enrolled either in the *Milicias* or *Ordenanzas*. The ɪrmer were obliged to serve beyond the boundaries of the :ovince, the latter only at home. The chief cities received .unicipal constitutions, as in Portugal. Thome de Sousa as the first person nominated to the important post of ɔvernor-general. He was instructed to build a strong city ı Bahia and to establish there the seat of his government. ı pursuance of his commission he arrived at Bahia in pril 1549, with a fleet of six vessels, on board of which ere three hundred and twenty persons in the king's pay, ɪur hundred convicts, and about three hundred free ɔlonists. Care had been taken for the spiritual wants of ıe provinces by associating six Jesuits with the expeition.

Old Caramaru, who still survived, rendered the governor essential service by gaining for his countrymen the good will of the natives. The new city was established where Bahia still stands. Within four months one hundred houses were built, and surrounded by a mud wall. Sugar plantations were laid out in the vicinity. During the four years of Sousa's government there were sent out at different times supplies of all kinds, female orphans of noble families, who were given in marriage to the officers, and portioned from the royal estates, and orphan boys to be educated by the Jesuits. The capital rose rapidly in importance, and the captaincies learned to regard it as a common head and centre of wealth. Meanwhile the Jesuits undertook the moral and religious culture of the natives, and of the scarcely less savage colonists. Strong opposition was at first experienced from the gross ignorance of the Indians, and the depravity of the Portuguese, fostered by the licentious encouragement of some abandoned priests who had found their way to Brazil. Over these persons the Jesuits had no authority; and it was not until the arrival of the first bishop of Brazil in 1552, that anything like an efficient check was imposed upon them. Next year Sousa was succeeded by Duarte da Costa, who brought with him a reinforcement of Jesuits, at the head of whom was Luis de Gran, appointed, with Nobrega the chief of the first mission, joint provincial of Brazil.

Nobrega's first act was one which has exercised the most beneficial influence over the social system of Brazil, namely, the establishment of a college on the then unreclaimed plains of Piratininga. It was named S. Paulo, and has been at once the source whence knowledge and civilization have been diffused through Brazil, and the nucleus of a colony of its manliest and hardiest citizens, which sent out successive swarms of hardy adventurers to people the interior. The good intentions of the Jesuits were in part frustrated by the opposition of Duarte the governor; and it was not until 1558, when Mem de Sa was sent out to supersede him, that their projects were allowed free scope.

Rio de Janeiro was first occupied by French settlers. Nicholas Durand de Villegagnon, a bold and skilful seaman, having visited Brazil, saw at once the advantages which might accrue to his country from a settlement there. In order to secure the interest of Coligny, he gave out that his projected colony was intended to serve as a place of refuge for the persecuted Huguenots. Under the patronage of that admiral, he arrived at Rio de Janeiro in 1558 with a train of numerous and respectable colonists. As soon, however, as he thought his power secure, he threw off the mask, and began to harass and oppress the Huguenots by every means he could devise. Many of them were forced by his tyranny to return to France; and ten thousand Protestants, ready to embark for the new colony, were deterred by their representations. Villegagnon, finding his force much diminished in consequence of his treachery, sailed for France in quest of recruits; and during his absence the Portuguese governor, by order of his court, attacked and dispersed the settlement. For some years the French kept up a kind of bush warfare; but in 1567 the Portuguese succeeded in establishing a settlement at Rio.

Mem de Sa continued to hold the reins of government in Brazil upon terms of the best understanding with the clergy, and to the great advantage of the colonies, for fourteen years. On the expiration of his power, which was nearly contemporary with that of his life, an attempt was made to divide Brazil into two governments; but this having failed, the territory was reunited in 1578, the year in which Diego Laurenço da Veiga was appointed governor. At this time the colonies, although not yet independent of supplies from the mother country, were in a flourishing condition; but the usurpation of the crown

of Portugal by Philip II. changed the aspect of affairs. Brazil, believed to be inferior to the Spanish possessions in mines, was consequently abandoned in comparative neglect for the period intervening between 1578 and 1640, during which it continued an apanage of Spain.

No sooner had Brazil passed under the Spanish crown, than English adventurers directed their hostile enterprises against its shores. In 1586 Witherington plundered Bahia; in 1591 Cavendish burned S. Vincente; in 1595 Lancaster took Olinda. These exploits, however, were transient in their effects. In 1612 the French attempted to found a permanent colony in the island of Marajó, where they succeeded in maintaining themselves till 1618. This attempt led to the erection of Maranhão and Pará into a separate *Estado*. But it was on the part of the Dutch that the most skilful and pertinacious efforts were made for securing a footing in Brazil; and they alone of all the rivals of the Portuguese have left traces of their presence in the national spirit and institutions of Brazil.

The success of the Dutch East India Company led to the establishment of a similar one for the West Indies, to which a monopoly of the trade to America and Africa was granted. This body despatched in 1624 a fleet against Bahia. The town yielded almost without a struggle. The fleet soon after sailed, a squadron being detached against Angola, with the intention of taking possession of that colony, in order to secure a supply of slaves The Portuguese, in the meanwhile, began to collect for the purpose of expelling the permanent intruders, and the hearty co-operation of all the natives against the invaders having been obtained through the descendants of Caramaru, the Dutch were obliged to capitulate in May 1625. The honours bestowed upon the Indian chiefs for their assistance in this war broke down in a great measure the barrier between the two races; and there is at this day a greater admixture of their blood among the better classes in Bahia than is to be found elsewhere in Brazil.

In 1630 the Dutch attempted again to effect a settlement; and Olinda yielded after a feeble resistance. They were unable, however, to extend their power beyond the limits of the town, until the arrival of Count Maurice of Nassau in 1630. His first step was to introduce a regular government among his countrymen; his second, to send to the African coast one of his officers, who took possession of a Portuguese settlement, and thus secured a supply of slaves. In the course of four years, the limited period of his government, he succeeded in confirming the Dutch supremacy along the coast of Brazil from the mouth of the S. Francisco to Maranhão. He promoted the amalgamation of the different races, and sought to conciliate the Portuguese by the confidence he reposed in them. His object was to found a great empire; but this was a project at variance with the wishes of his employers—an association of merchants, who were dissatisfied because the wealth which they expected to see flowing into their coffers was expended in promoting the permanent interests of a distant country. Count Maurice was recalled in 1644 His successors possessed neither his political nor his military talents, and had to contend with more energetic enemies.

In 1640 the revolution which placed the house of Bragança on the throne of Portugal restored Brazil to masters more inclined to promote its interests and assert its possession than the Spaniards. It was indeed high time that some exertion should be made. The northern provinces had fallen into the power of Holland; the southern, peopled in a great measure by the hardy descendants of the successive colonists who had issued on all sides from the central establishment of S. Paulo, had learned from their habits of unaided and successful enterprise to court independence. They had ascended the waters of the Paraguay to their sources. They had extended their limits southwards till they reached the Spanish settlements on La Plata. They had reduced to slavery numerous tribes of the natives. They were rich in cattle, and had commenced the discovery of the mines. When, therefore, the inhabitants of S. Paulo saw themselves about to be transferred, as a dependency of Portugal, from one master to another, they conceived the idea of erecting their country into an independent state. Their attempt, however, was frustrated by Amador Bueno, the person whom they had selected for their king. When the people shouted "Long live King Amador," he cried out "Long live João IV.," and took refuge in a convent. The multitude, left without a leader, acquiesced, and this important province was secured to the house of Bragança.

Rio and Santos, although both evinced a desire of independence, followed the example of the Paulistas. Bahia, as capital of the Brazilian states, felt that its ascendency depended upon the union with Portugal. The Government thus left in quiet possession of the rest of Brazil, had time to concentrate its attention upon the Dutch conquests. The crown of Portugal was, however, much too weak to adopt energetic measures. The tyranny of the successors of Nassau, by alienating the minds of the Portuguese and natives, drove them to revolt before any steps were taken in the mother country for the reconquest of its colonies. João Fernandes Vieyra, a native of Madeira, organized the insurrection which broke out in 1645. This insurrection gave birth to one of those wars in which a whole nation, destitute of pecuniary resources, military organization, and skilful leaders, is opposed to a handful of soldiers advantageously posted and well officered. But brute force is unable to contend with scientific valour. Vieyra, who had the sense to see this, repaired to the court of Portugal, and discovering the weakness and poverty of the executive, suggested the establishment of a company similar to that which in Holland had proved so successful. His plan, notwithstanding the opposition of the priests, was approved of, and in 1649 the Brazil Company of Portugal sent out its first fleet. After a most sanguinary war, Vieyra was enabled in 1654 to present the keys of Olinda to the royal commander, and to restore to his monarch the undivided empire of Brazil. After this, except some inroads on the frontiers, the only foreign invasion which Brazil had to suffer was from France. In 1710 a squadron, commanded by Duclerc, disembarked 1000 men, and attacked Rio de Janeiro. After having lost half of his men in a battle, Duclerc and all his surviving companions were made prisoners. The governor treated them cruelly. A new squadron with 6000 troops was intrusted to the famous admiral Duguay Trouin to revenge this injury. They arrived at Rio on the 12th September 1711. After four days of hard fighting the town was taken. The governor retreated to a position out of it, and was only awaiting reinforcements from Minas to retake it; but Duguay Trouin threatening to burn it, he was obliged on the 10th October to sign a capitulation, and pay to the French admiral 610,000 crusados, 500 cases of sugar, and provisions for the return of the fleet to Europe. Duguay Trouin departed to Bahia to obtain fresh spoils; but having lost in a storm two of his best ships, with an important part of the money received, he renounced this plan and returned directly to France.

After this the Portuguese governed undisturbed their colony. The approach of foreign traders was prohibited, while the regalities reserved by the crown drained the country of a great proportion of its wealth.

The important part which the inhabitants of São Paulo have played in the history of Brazil has been already adverted to. The establishment of the Jesuit college had attracted settlers to its neighbourhood, and frequent

marriages had taken place between the Indians of the district and the colonists. A hardy and enterprising race of men had sprung from this mixture, who, first searching whether their new country were rich in metals, soon began adventurous raids into the interior, making excursions also against the remote Indian tribes with a view to obtaining slaves, and from the year 1629 onwards repeatedly attacked the Indian reductions of the Jesuits in Paraguay, although both provinces were then nominally subject to the crown of Spain. Other bands penetrated into Minas and still farther north and westward, discovering mines there and in Goyaz and Cuyabá. New colonies were thus formed round those districts in which gold had been found, and in the beginning of the 18th century five principal settlements in Minas Geraes had been elevated by royal charter to the privileges of towns. In 1720 this district was separated from São Paulo, to which it had previously been dependent. As early as 1618 a code of laws for the regulation of the mining industry had been drawn up by Philip III., the executive and judicial functions in the mining districts being vested in a *provedor*, and the fiscal in a treasurer, who received the royal fifths and superintended the weighing of all the gold, rendering a yearly account of all discoveries and produce. For many years, however, these laws were little more than a dead letter. The same infatuated passion for mining speculation which had characterized the Spanish settlers in South America now began to actuate the Portuguese; labourers and capital were drained off to the mining districts, and Brazil, which had hitherto in great measure supplied Europe with sugar, sank before the competition of the English and French. A new source of wealth was now opened up; some adventurers from Villa do Principe in Minas, going north to the Seria Frio, made the discovery of diamonds about the year 1710, but it was not till 1730 that the discovery was for the first time announced to the Government, which immediately declared them *regalia*. While the population of Brazil continued to increase, the moral and intellectual culture of its inhabitants was left in great measure to chance; they grew up with those robust and healthy sentiments which are engendered by the absence of false teachers, but with a repugnance to legal ordinances, and encouraged in their ascendency over the Indians to habits of violence and oppression. The Jesuits from the first moment of their landing in Brazil had constituted themselves the protectors of the natives, and though strenuously opposed by the colonists and ordinary clergy, had gathered the Indians together in many *aldeas*, over which officials of their order exercised spiritual and temporal authority. A more efficacious stop, however, was put to the persecution of the Indians by the importation of large numbers of negroes from the Portuguese possessions in Africa, these being found more active and serviceable than the native tribes.

The Portuguese Government, under the administration of Carvalho, afterwards marquis of Pombal, attempted to extend to Brazil the bold spirit of innovation which directed all his efforts. The proud minister had been resisted in his plans of reform at home by the Jesuits, and, determining to attack the power of the order, first deprived them of all temporal power in the state of Maranhão and Pará. These ordinances soon spread to the whole of Brazil, and a pretext being found in the suspicion of Jesuit influence in some partial revolts of the Indian troops on the Rio Negro, the order was expelled from Brazil under circumstances of great severity in 1760. The Brazilian Company founded by Vieyra, which so materially contributed to preserve its South American possessions to Portugal, had been abolished in 1721 by João V.; but such an instrument being well suited to the bold spirit of Pombal, he established a chartered company again in 1755, to trade exclusively with Maranhão and Pará; and in 1759, in spite of the remonstrance of the British Factory at Lisbon, formed another company for Paraiba and Pernambuco. Pombal's arrangements extended also to the interior of the country, where he extinguished at once the now indefinite and oppressive claims of the original donatories of the captaincies, and strengthened and enforced the regulations of the mining districts. The policy of many of Pombal's measures is more than questionable; but his admission of all races to equal rights in the eye of the law, his abolition of feudal privileges, and the firmer organization of the powers of the land which he introduced, powerfully co-operated towards the development of the capabilities of Brazil. Yet on the death of his king and patron in 1777, when court intrigue forced him from his high station, he who had done so much for his country's institutions was reviled on all hands.

The most important feature in the history of Brazil during the first thirty years following the retirement of Pombal was the conspiracy of Minas in 1789. The successful issue of the recent revolution of the English colonies in North America had filled the minds of some of the more educated youth of that province; and in imitation, a project to throw off the Portuguese yoke was formed,—a cavalry officer, Silva Xavier, nicknamed Tira-dentes (tooth-drawer), being the chief conspirator. But the plot being discovered during their inactivity, the conspirators were banished to Africa, and Tira-dentes, the leader, was hanged. Thenceforward affairs went on prosperously; the mining districts continued to be enlarged; the trading companies of the littoral provinces were abolished, but the impulse they had given to agriculture remained.

Removed from all communication with the rest of the world except through the mother country, Brazil remained unaffected by the first years of the great revolutionary war in Europe. Indirectly, however, the fate of this isolated country was decided by the consequences of the French Revolution. Brazil is the only instance of a colony becoming the seat of the Government of its own mother country, and this was the work of Napoleon. When he resolved upon the invasion and conquest of Portugal, the Prince Regent, afterwards Dom João VI., having no means of resistance, decided to take refuge in Brazil. He created a regency in Lisbon, and departed for Brazil on the 29th November 1807, accompanied by the Queen Donna Maria I., the royal family, all the great officers of state, a large part of the nobility, and numerous retainers. They arrived at Bahia on the 21st January 1808, and were received with enthusiasm. The regent was requested to establish there the seat of his government, but a more secure asylum presented itself in Rio de Janeiro, where the royal fugitives arrived on the 7th of March. Before leaving Bahia Don John took the first step to emancipate Brazil, opening its ports to foreign commerce, and permitting the export of all Brazilian produce under any flag, the royal monopolies of diamonds and Brazil-wood excepted. Once established in Rio de Janeiro, the government of the regent was directed to the creation of an administrative machinery for the dominions that remained to him as they existed in Portugal. Besides the ministry which had come with the regent, the council of state, and the departments of the four ministries of home, finances, war, and marine then existing, there were created in the course of one year a supreme court of justice, a board of patronage and administration of the property of the church and military orders, an inferior court of appeal, the court of exchequer and royal treasury, the royal mint, bank of Brazil, royal printing-office, powder-mills on a large scale, and a supreme military court. The maintenance of the court, and the salaries of so large a number of high officials, entailed the

imposition of new taxes to meet these expenses. Notwithstanding this the expenses continued to augment, and the Government had recourse to the reprehensible measure of altering the money standard, and the whole monetary system was soon thrown into the greatest confusion, a state of things from which the country suffers even at the present day. The bank, in addition to its private functions, farmed many of the *regalia*, and was in the practice of advancing large sums to the state, transactions which gave rise to extensive corruption, and terminated some years later in the breaking of the bank.

Thus the Government of the prince regent began its career in the new world with dangerous errors in the financial system; yet the increased activity which a multitude of new customers and the increase of circulating medium gave to the trade of Rio, added a new stimulus to the industry of the whole nation. Numbers of English artisans and shipbuilders, Swedish iron-founders, German engineers, and French manufacturers sought fortunes in the new country, and diffused industry by their example.

In the beginning of 1809, in retaliation of the occupation of Portugal, an expedition was sent from Pará to the French colony of Guiana, and after some fighting this part of Guiana was incorporated with Brazil. This conquest was, however, of short duration; for, by the treaty of Vienna in 1815, the colony was restored to France. Its occupation contributed to the improvement of agriculture in Brazil; it had been the policy of Portugal up to this time to separate the productions of its colonies, to reserve sugar for Brazil, and spices to the East Indies, and to prohibit the cultivation of these in the African possessions. Now, however, many plants were imported not only from Guiana but from India and Africa, cultivated in the Royal Botanic Garden, and thence distributed. The same principle which dictated the conquest of French Guiana originated attempts to seize the Spanish colonies of Monte Video and Buenos Ayres, Portugal being also at war with Spain. The chiefs of these colonies were invited to place them under the protection of the Portuguese crown, but these at first affecting loyalty to Spain declined the offer, then threw off the mask and declared themselves independent, and the Spanish governor, Elio, was afterwards defeated by Artigas, the leader of the independents.

The inroads made on the frontiers of Rio Grande and São Paulo decided the court of Rio to take possession of Monte Video; a force of 5000 troops was sent thither from Portugal, together with a Brazilian corps; and the irregulars of Artigas, unable to withstand disciplined troops, were forced, after a total defeat, to take refuge beyond the River Uruguay. The Portuguese took possession of the city of Monte Video in January 1817, and the territory of Missiones was afterwards occupied. The importance which Brazil was acquiring decided the regent to give it the title of kingdom, and by decree of the 16th January 1815, the Portuguese sovereignty thenceforward took the title of the United Kingdom of Portugal, Brazil, and Algarves. Thus the old colonial government disappeared even in name. In March 1816 the Queen Donna Maria I. died, and the prince regent became king under the title of Dom João VI.

Although Brazil had now become in fact the head of its own mother country, the government was not in the hands of Brazilians, but of the Portuguese, who had followed the court. The discontent arising among Brazilians from this cause was heightened by a decree assigning a heavy tax on the chief Brazilian custom houses, to be in operation for forty years, for the benefit of the Portuguese noblemen who had suffered during the war with France. The amiable character of the king preserved his own popularity, but the Government was ignorant and profligate, justice was ill administered, negligence and disorder reigned in all its departments. Nor was the discontent less in Portugal on account of its anomalous position. These causes and the fermentation of liberal principles produced by the French Revolution originated a conspiracy in Lisbon in 1817, which was, however, discovered in time to prevent its success. A similar plot and rebellion took place in the province of Pernambuco, where the inhabitants of the important commercial city of Recife were jealous of Rio and the sacrifices they were compelled to make for the support of the luxurious court there. Another conspiracy to establish a republican government was promptly smothered in Bahia, and the outbreak in Pernambuco was put down after a republic had been formed there for ninety days. Still the progress of the republican spirit in Brazil caused Dom João to send to Portugal for bodies of picked troops, which were stationed throughout the provincial capitals. In Portugal the popular discontent produced the revolution of 1820, when representative government was proclaimed—the Spanish constitution of 1812 being provisionally adopted. In Rio, the Portuguese troops with which the king had surrounded himself as a defence against the liberal spirit of the Brazilians, took up arms on the 26th February 1821, to force him to accept the system proclaimed in Portugal. The prince Dom Pedro, heir to the crown, who now for the first time took part in public affairs, actively exerted himself as a negotiator between the king and the troops, who were joined by bodies of the people. After attempting a compromise the king finally submitted, took the oath, and named a new ministry. The idea of free government filled the people with enthusiasm, and the principles of a representative legislature were freely adopted, the first care being for the election of deputies to the *Cortes* of Lisbon to take part in framing the new constitution. As the king could not abandon Portugal to itself he determined at first to send the prince thither as regent, but Dom Pedro had acquired such popularity by his conduct in the revolution, and had exhibited such a thirst for glory, that the king feared to trust his adventurous spirit in Europe, and decided to go himself. The Brazilian deputies on arriving in Lisbon expressed dissatisfaction with the Cortes for having begun the framing of the constitution before their arrival, for Brazil could not be treated as a secondary part of the monarchy. Sharp discussions and angry words passed between the Brazilian and Portuguese deputies, the news of which excited great discontent in Brazil. An insulting decree was passed in the Cortes, ordering the prince Dom Pedro to come to Europe, which filled the Brazilians with alarm; they foresaw that without a central authority the country would fall back to its former colonial state subject to Portugal. The Provisional Government of São Paulo, influenced by the brothers Andradas, began a movement for independence by asking the prince to disobey the Cortes and remain in Brazil, and the council of Rio de Janeiro followed with a similar representation, to which the prince assented. The Portuguese troops of the capital at first assumed a coercive attitude, but were forced to give way before the ardour and military preparations of the Brazilians, and submitted to embark for Portugal. These scenes were repeated in Pernambuco, where the Portuguese, after various conflicts, were obliged to leave the country; in Bahia, however, as well as in Maranhão and Pará, the Portuguese prevailed. In Rio the agitation for independence continued. The two brothers Andradas were called to the ministry; and the municipal council conferred upon the prince regent the title of Perpetual-Defender of Brazil. With great activity he set off to the central provinces of Minas and São Paulo to suppress disaffected movements and direct the revolution. In São Paulo, on the 7th of September 1822, he proclaimed the independence of Brazil. On his return to Rio de

Janeiro on the 12th of October he was proclaimed constitutional emperor with great enthusiasm.

The Cortes at Lisbon chose Bahia as a centre for resisting the independence, and large forces were sent thither. But the city was vigorously besieged by the Brazilians by land, and finally the Portuguese were obliged to re-embark on the 2d of July 1823. A Brazilian squadron, under command of Lord Cochrane, attacked the Portuguese vessels, embarrassed with troops, and took several of them. Taylor, another Englishman in Brazilian service, followed the vessels across the Atlantic, and even captured some of the ships in sight of the land of Portugal. The troops in Monte Video also embarked for Portugal, and the Banda Oriental remained a part of Brazil with the title of the *Provincia Cisplatina*. Before the end of 1823 the authority of the new emperor and the independence of Brazil were undisputed throughout the whole country.

Republican movements now began to spread, to suppress which the authorities made use of the Portuguese remaining in the country; and the disposition of the emperor to consider these as his firmest supporters much influenced the course of his Government and his future destiny. The two Andradas, who imagined they could govern the young emperor as a sovereign of their own creation, encountered great opposition in the constitutional assembly, which had been opened in Rio in May 1823, to discuss the project of a new constitution. In July the emperor resolved to dismiss them and form a new ministry, but against this the brothers raised a violent opposition. In November the emperor put an end to the angry debates which ensued in the assembly by dissolving it, exiling the Andradas to France, and convoking a new assembly to deliberate on a proposed constitution more liberal than the former project. The proclamation of a republic in the provinces of Pernambuco and Ceará, with the rebellion of the Cisplatina province, favoured by Buenos Ayres and its ultimate loss to Brazil, were the result of the *coup d'état* of November 1823. The Brazilians were universally discontented,—on one side fearing absolutism if they supported the emperor, on the other anarchy if he fell. Knowing the danger of an undefined position, the emperor caused the councils to dispense with their deliberations, and adopt, as the constitution of the empire, the project framed by the council of state. Accordingly, on March 25, 1824, the emperor swore to the constitution with great solemnity and public rejoicings. By this stroke of policy he saved himself and Brazil. Negotiations were opened in London between the Brazilian and Portuguese plenipotentiaries, treating for the recognition of the independence of Brazil; and on the 25th of August 1825 a treaty was signed by which the Portuguese king, Dom João VI., assumed the title of Emperor of Brazil, and immediately abdicated in favour of his son, acknowledging Brazil as an independent empire, but the treaty obliged Brazil to take upon herself the Portuguese debt, amounting to nearly two millions sterling.

The rebellion of the Banda Oriental was followed by a declaration of war with Buenos Ayres which had supported it, and operations by sea and land were conducted against that republic in a feeble way. Meanwhile the well-deserved popularity of the emperor began to decline. He had given himself up to the influence of the Portuguese; the most popular men who had worked for the independence were banished; and a continual change of ministry showed a disposition on the part of the sovereign to prosecute obstinately measures of which his advisers disapproved. His popularity was regained, however, to some extent, when, on the death of his father, he was unanimously acknowledged king of Portugal, and especially when he abdicated that crown in favour of his daughter, Donna Maria; but his line of policy was not altered, and commercial treaties entered into with European states conceding them favours, which were popularly considered to be injurious to Brazilian trade, met with bitter censure.

During the year 1827 the public debt was consolidated, and a department was created for the application of a sinking fund.

The year 1828 was a calamitous one for Brazil. It began with the defeat of the Brazilian army by the Argentine forces, and this entirely through the incapacity of the commander-in-chief; and misunderstandings, afterwards compensated by humbling money-payments on the part of Brazil, arose with the United States, France, and England, on account of merchant vessels captured by the Brazilian squadron blockading Buenos Ayres. Financial embarrassments increased to an alarming extent; the emperor was compelled by the British Government to make peace with Buenos Ayres and to renounce the Banda Oriental; and to fill the sum of disasters Don Miguel had treacherously usurped the crown of Portugal. It was under these unlucky auspices that the elections of new deputies took place in 1829. As was expected the result was the election everywhere of ultra-liberals opposed to the emperor, and in the succeeding year people everywhere exhibited their disaffection. During the session of 1830 the chambers adopted a criminal code in which punishment by death for political offences was abolished. It was openly suggested in the journals to reform the constitution by turning Brazil into independent federal provinces, governed by authorities popularly elected, as in the United States. Alarmed at length at the ground gained by this idea in the provinces, the emperor set off to Minas to stir up the former enthusiasm in his favour from recollections of the independence, but was coldly received. On his return to Rio in March 1831 scenes of disorder occurred, and great agitation among the Liberal party. Imagining himself sure of a brilliant destiny in Europe if he lost his Brazilian crown, the emperor attempted to risk a decisive attack against the Liberals, and to form a new ministry composed of men favourable to absolutism. This step caused excited public meetings in the capital, which were joined in by the troops, and deputations went to ask the emperor to dismiss the unpopular ministry. He replied by dissolving the ministry without naming another, and by abdicating the crown in favour of the heir apparent, then only five years of age. Dom Pedro immediately embarked in an English ship, leaving the new Emperor Dom Pedro II. and the princesses Januaria, Francisca, and Paula. The subsequent career of this unfortunate prince belongs to the history of Portugal.

A provisional and afterwards a permanent regency, composed of three members, was now formed in Brazil, but scenes of disorder succeeded, and discussions and struggles between the republican party and the Government, and a reactionary third party in favour of the restoration of Dom Pedro, occupied the succeeding years. In 1834 a reform which was well received consisted in the alteration of the regency, from that of three members elected by the legislative chambers, to one regent chosen by the whole of the electors in the same manner as the deputies; and the councils of the provinces were replaced by legislative provincial assemblies. Virtually, this was a republican government like that of the United States, for no difference existed in the mode of election of the regent from that of a president. The ex-minister Feijoó was chosen for this office. With the exception of Pará and Rio Grande the provinces were at peace, but these were in open rebellion; the former was reduced to obedience, but in the latter, though the imperial troops occupied the town, the country

was ravaged by its warlike inhabitants. The regent was now accused of conniving at this rebellion, and the opposition of the Chamber of Deputies became so violent as to necessitate his resignation. Araujo Lima, minister of the home department, who strove to give his government the character of a monarchical reaction against the principles of democracy, was chosen by a large majority in his stead. The experiment of republican government had proved so discreditable, and had so wearied the country of cabals, that men hitherto known for their sympathy with democratic principles became more monarchical than the regent himself; and under this influence a movement to give the regency into the hands of the Princess Donna Januaria, now in her 18th year, was set on foot. It was soon perceived, however, that if the empire could be governed by a princess of eighteen it could be managed better by the emperor himself, who was then fourteen.

A bill was accordingly presented to legislature dispensing with the age of the emperor and declaring his majority, which after a noisy discussion was carried. The majority of the Emperor Dom Pedro II. was proclaimed on the 23d July 1840. Several ministries, in which various parties predominated for a time, now governed the country till 1848, during which period the rebellious province of Rio Grande was pacified, more by negotiation than force of arms. In 1848 hostilities were roused with the British Government through the neglect shown by the Brazilians in putting in force a treaty for the abolition of the slave trade, which had been concluded as far back as 1826; on the other hand the governor of Buenos Ayres, General Rosas, was endeavouring to stir up revolution again in Rio Grande. The appearance of yellow fever in 1849, until then unknown in Brazil, was attributed to the importation of slaves. Public opinion declared against the traffic; severe laws were passed against it, and were so firmly enforced that in 1853 not a single disembarkation took place. The ministry of the Visconde de Olinda in 1849 entered into alliances with the governors of Monte Video, Paraguay, and the states of Entre Rios and Corrientes, for the purpose of maintaining the integrity of the republics of Uruguay and Paraguay, which Rosas intended to re-unite to Buenos Ayres, and the troops of Rosas which besieged Monte Video were forced to capitulate. Rosas then declared war formally against Brazil. An army of Correntine, Uruguayan, and Brazilian troops, under General Urquiza, assisted by a Brazilian naval squadron, advanced on Buenos Ayres, completely routed the forces of Rosas, and crushed for ever the power of that dictator. From 1844 Brazil was free from intestine commotions, and had resumed its activity. Public works and education were advanced, and the finances rose to a degree of prosperity previously unknown.

In 1855 the emperor of Brazil sent a squadron of eleven men-of-war and as many transports up the Paraná to adjust several questions pending between the empire and the Republic of Paraguay, the most important of which was that of the right of way by the Paraguay River to the interior Brazilian province of Matto Grosso. This right had been in dispute for several years. The expedition was not permitted to ascend the River Paraguay, and returned completely foiled in its main purpose. Though the discord resulting between the states on account of this failure was subsequently allayed for a time by a treaty granting to Brazil the right to navigate the river, every obstacle was thrown in the way by the Paraguayan Government, and indignities of all kinds were offered not only to Brazil but to the representatives of the Argentine and the United States. In 1864 the ambitious dictator of Paraguay, Francisco Solano Lopez, without previous declaration of war, captured a Brazilian vessel in the Paraguay, and rapidly followed up this outrage by an armed invasion of the provinces of Matto Grosso and Rio Grande in Brazil, and that of Corrientes in the Argentine Republic. A triple alliance of the invaded states with Uruguay ensued, and the tide of war was soon turned from being an offensive one on the part of Paraguay to a defensive struggle within that republic against the superior number of the allies. So strong was the natural position of Paraguay, however, and so complete the subjection of its inhabitants to the will of the dictator, that it was not until the year 1870, after the republic had been completely drained of its manhood and resources, that the long war was terminated by the capture and death of Lopez with his last handful of men by the pursuing Brazilians. From its duration and frequent battles and sieges this war involved an immense sacrifice of life to Brazil, the army in the field having been constantly maintained at between 20,000 and 30,000 men, and the expenditure in maintaining it was very great, having been calculated at upwards of fifty millions sterling. Large deficits in the financial budgets of the state resulted, involving increased taxation and the contracting of loans from foreign countries.

Notwithstanding this the sources of public wealth in Brazil were unaffected, and commerce continued steadily to increase. A grand social reform was effected in the law passed in September 1871, which enacted that from that date every child born of slave parents should be free, and also declared all the slaves belonging to the state or to the imperial household free from that time. The same law provided an emancipation fund, to be annually applied to the ransom of a certain number of slaves owned by private individuals. Since that time the emancipation of slaves has gone on rapidly, the work having been promoted largely by the slave owners and by private philanthropy. It is estimated that since the cessation of the importing of slaves in 1853, and especially after the enactment of 1871, not less than a million of slaves have obtained their freedom; and the total extinction of slavery within the empire is not far distant. From the extremely rapid progress of this movement difficulties have been experienced in a considerable degree in procuring a sufficient supply of labour for the Brazilian plantations, but the general effect of the law has been to give new directions to the employment of capital, and the construction of railroads and telegraphs, and the improvement of internal communication by roads and rivers have been largely promoted. Attention has also been strongly directed towards the further development of the provinces by the increase of European immigration. Enterprises of all kinds have multiplied, and public instruction has received a vigorous impulse.

The Emperor Dom Pedro II. and the empress, a sister of the king of Naples, are universally beloved and respected for their intellectual and moral endowments, and their affectionate interest in the welfare of their subjects. Princess Isabel, born in July 1846, and her son born in October 1875, are their only surviving offspring.

Until after the year 1872, when a complete census of the empire was begun, every estimate of the population of Brazil was based upon the official returns of 1817–18, and these have consequently been mere approximations, varying very considerably in the hands of different authors. In the first census referred to the whole number of people was 4,396,000, including an estimated number of 800,000 Indians; in 1850 the total was reckoned roundly at 7,000,000; and in 1860 at 8,000,000.

In the following table the results of the census of 1872 have been incorporated, as far as these have yet been published, the remaining figures being made up from the estimates formerly given for each of the provinces. The

table also contains the area of each of the provinces, from planimetric calculations made in Gotha in 1872, the official returns on this subject being most obviously exaggerated, and claiming for the empire an area equal to that of Brazil with all the surrounding republics on the north and west taken together.

Provinces.	Area in English Square Miles.	Population.			Chief Towns.
		Free.	Slave.	Total.	
Alto Amazonas	753,469	56,631	979	57,610*	Manáos.
Grão Pará	412,467	232,622	27,199	259,821	Pará or Belem.
Maranhão	141,651	284,101	74,939	359,040	S. Luiz do Maranhão.
Piauhy	81,779	178,427	23,785	202,222	Therezina.
Ceará	50,262	689,773	31,913	721,686*	Fortaleza.
Rio Grande do Norte	20,130	220,959	13,020	233,979	Natal.

* The population figures marked thus are the results of the census begun in 1872; the others are made up from the most recent provincial estimates.

Races. The population of Brazil presents a number of distinct types as well as many varieties blended from these. The aboriginal Indians of the country have to a large extent become amalgamated with the settled population, especially in the eastern or maritime provinces; but in the vast forests and grass plains of the interior they remain in a more or less completely savage condition. In general description the Indians are of copper colour, of middle height, thick-set, broad-chested, and muscular, with well-shaped limbs and small hands and feet. The hair is black, thick, and straight; the features broad, cheek bones not generally prominent, eyes black and sometimes oblique, like those of the Tatar races of Eastern Asia; they are of apathetic and undemonstrative nature. Their tribes and subdivisions, scattered over the enormous interior area, are countless; though these may vary somewhat in physical characteristics, in language, and customs, they belong apparently to one original stock, called by ethnographers, the Tupi-Guarani. Most of the semi-civilized Indians of Brazil, especially those of the eastern provinces, speak the Lingoa-Geral, a language adapted by the Jesuit missionaries from the original idiom of the Tupinambaras, one of the larger eastern tribes. The less civilized and savage Indians are termed collectively Gentios (heathens) by the Brazilians. The only tribe of the eastern coast-lands which has resisted civilization in some portion of its numbers is that of the Botocudos, inhabiting the forests between the Rio Doce and Rio Pardo, sunk in the lowest barbarism and fast disappearing. From the European—chiefly Portuguese—immigrants, by mixture with the native Indians, are descended the Mamelucos, a variety which first made itself prominent in inland raids and conquests in the southern provinces, especially from the neighbourhood of São Paulo, whence they were named Paulistas. The negroes, introduced from Africa in immense numbers, constitute one of the largest elements of population. From these, by intercourse with the white race, have sprung the mulattoes, and the descendants of these, becoming progressively whiter. The Brazilian creoles, who call themselves Brazileiros, descendants of these mixed races, prove little inferior in capacity, physical strength, or intelligence to the pure race of Portuguese. The rapidly progressing emancipation of the African slaves in Brazil has been referred to previously. A strong desire pervades those of the slaves not born in Brazil, even though they may have been made captives when mere infants, to return to Africa. Associations have been formed among them in many parts, both for the purchase of the freedom of those still in bondage and for sending the freedmen back to their native country, a movement which has actually taken place to a considerable extent. A result of the emancipation and consequent deficiency of labour, chiefly felt in the neighbourhood of Rio and the provinces to the south of it, has been the deportation of large numbers of slaves from the northern to the more southerly provinces.

An increase in the population of Brazil being one of the prime requisites for the advancement of the country, the state encourages immigration by every possible means, and especially of late years, since the labour question began to be serious, has made great efforts to entice European colonists. For this end an official agency was established at Rio de Janeiro in 1864, to provide for the conveyance and landing of colonists and for forwarding these to the various localities. The passage from whatever country to Brazil, and thence to the special colony inland, is also defrayed by Government, and other advantages are held out. Notwithstanding the zeal with which the many schemes of state or private colonization in Brazil have been promoted, the results have been far from satisfactory; as far as British, German, and Swiss experience goes these have been in many instances very disastrous; and whatever seductive representation of advantages may be held out, any scheme for the introduction of north European colonists into Brazil cannot be too strongly deprecated. Not only is the climate and soil, except perhaps of the extreme southern province, unsuited to the Anglo-Saxon race, but the abandonment of nationality and of language, of customs and laws, and the obnoxious surroundings, prove fatal to success. Colon

The chief state colonies are at the following places. *Santa Leopoldina*, thirty-three miles distant from the capital of the province of Espiritu-Santo, having free access to it by the Sta. Maria River,—is chiefly a German, Swiss, and Dutch colony. *Rio Novo* is in the same province. *Mucury*, in the province of Minas Geraes, is also a German colony. *Canarea* in the province of São Paulo, 14 miles from the sea-coast and near the town of the same name, is mainly English. *Assungay*, 62 miles from the capital of the province of Paraná, *Itajahy*, 29 miles from the port of the same name in the province of Sta. Catharina, and *Blumenau*, also in that province on the navigable River Itajahy, are chiefly German. *Sta. Maria de Soledade*, near São Leopoldo, in Rio Grande do Sul, is also a state colony. Several places long colonized have passed out of the colonial régime, and have been formed into municipalities. Such are *São Leopoldo* in Rio Grande, *Santa Isabel* in the province of Sta. Catharina, *Nova Friburgo* and *Petropolis* in elevated districts of the Organ Mountains in Rio de Janeiro.

Private and provincial colonies are rather numerous. Of these there are eight in Rio Grande do Sul, the chief being that of *Sta Cruz*; Sta Catharina has two; Minas Geraes and Bahia, each one. Taken together the state, provincial, and private colonies embraced, in 1873, upwards of 40,000 people. During the past two years the unsettled condition and financial difficulties of the La Plata states have thrown large numbers of foreign—chiefly Italian—settlers into destitution, and many hundreds of these have been induced, by the offer of free passage and land, to seek a new home in Brazil.

The Brazilian monarchy derives from the ancient monarchy of Portugal the principle of hereditary succession to

the crown. The laws of succession are defined with great distinctness in the constitution, and are the same as in England.

In Brazil there is no privileged aristocracy, but descent from the noble families of Portugal, length of time in the service of the country, or large fortune, gives a certain claim to the privileges of aristocracy readily admitted by the Brazilians. The emperor rewards services, according to their difficulty or importance, with the titles of marquis, count, baron, or knight (moços fidalgos). Titles are not hereditary, but if a son prove himself worthy of his father, he inherits his title. There are in the empire six orders of chivalry; those of the Southern Cross, the order of Dom Pedro I., and of the Rose, created by the first emperor between 1822 and 1829; and those of Christ, St Benoit of Aviz, and St Theodoric, adopted by Dom Pedro II. The senate represents the only element of aristocracy recognized by the constitution, and the democratic element preponderates, but its action is modified by the complicated system of election. The constitution established four powers,—the moderating, the legislative, the executive, and the judicial.

The *moderating* power is vested exclusively in the emperor as chief representative of the nation, that he may maintain the equilibrium and harmony of the other powers. He exercises this function with regard to the legislature by being empowered to choose the senators, to convoke or adjourn the general assembly, to dissolve the chamber of deputies, and to sanction the decrees of the assembly; as regards the executive, by appointing or dismissing at will the ministers of state; and over the judicial power, by suspending the magistrates, pardoning or commuting penalties, and granting amnesties. The person of the emperor is sacred, inviolable, and irresponsible.

The *legislative* power is vested, for the affairs of the empire, in the general legislative assembly with the sanction of the emperor, and for the provincial affairs in the provincial assemblies with the sanction of the president (governor) of the province. The general legislative assembly consists of two chambers, that of deputies and that of senators. The deputies are nominated by indirect election. Citizens, and even manumitted slaves, born in the empire, who possess an income of £22, 10s., choose the electors in parochial assemblies, and these electors nominate the deputies. The qualification for an elector is an annual income of £45; that of a deputy an income of £90. Minors, monks, and servants, are debarred from voting; naturalized foreigners, and persons not professing the religion of the state, are incapable of being elected deputies, but they can be senators. The deputies to the number of 122 are elected for four years, and must hold an annual session of four months, opening on the 3d of May. The senators (58 in number) are elected for life. Every province has a number of senators, equal to half its number of deputies; but they are nominated in triple lists, from which the emperor selects one-third. A senator must be forty years of age, and must possess a clear annual income of £180. The allowance of a senator is one-half more than that of a deputy. Each house nominates its own officers. When the two houses sit in general assembly, as at the opening and close of the session, to hear the emperor's speech, &c., the president of the senate presides, and the senators and deputies sit promiscuously. They sit apart and proceed by way of bill, when they make laws, interpret, and suspend them; they determine the public charges, and assess the contributions, &c. The chamber of deputies has the initiative in taxes, in recruiting, and in the choice of a new dynasty. The senate has the exclusive privilege of taking cognizance of offences committed by members of the imperial family, councillors of state, senators, and deputies, during the session; of enforcing the responsibility of secretaries and councillors of state; of convoking the assembly in case the emperor fail to do so within two months after the period fixed by law; and also of calling it together on the death of the emperor.

The *executive* power is vested in the emperor, assisted by his ministers and secretaries of state, who are responsible for treason, corruption, abuse of power, acts contrary to the liberty, security, or property of the citizens, and waste of public property. From this responsibility they cannot escape upon the plea of orders from the emperor. The executive functions are such as the convocation of the general ordinary assembly; the nomination of bishops, presidents, governors of provinces; commanders by sea and land, and ambassadors; the formation of alliances, and all foreign negotiations; the declaration of peace and war; and the granting letters of naturalization.

The ministers are seven, one for each of the departments of the empire and ecclesiastical affairs; justice; war; marine; finances; foreign affairs; and agriculture, commerce, and public works. One of these is president or premier. To these is superadded a council of state composed of twelve ordinary members, besides which it may have as many as twelve extraordinary members, all of them appointed for life. The council is divided into sections corresponding to the seven ministries, or sits in full meeting, presided over by the emperor. The prince or princess imperial, on attaining the age of eighteen, has a seat in this assembly. The council is merely consultative, and though its use is optional it is always heard on any important public question or appeal to the crown. The provincial governments are entrusted to a president in each, appointed by the executive power and immediately under its control: he is the supreme representative of government in the province, sanctions the resolutions of the provincial assemblies, and appoints provincial functionaries. The provincial assemblies, elected every two years by the same citizens who elect members of the chamber of deputies, deal only with matters immediately relating to the private or local interests of the province.

Every city, town, and village, with the surrounding district, has a municipal council composed of nine or seven members, elected directly by the citizens who possess an annual income of £22, 10s. This council is charged with all that concerns the good of the district, meets four times a year, besides extraordinary sessions, and every meeting may last as many days as may be found necessary for the expedition of business. They impose fines to a certain amount, and even enforce their decrees by a penalty of thirty days' imprisonment. They annually draw up a municipal budget, which is submitted to the provincial legislative assembly for approval. If their revenue and the produce of fines be not sufficient to defray expenses, an allowance from the provincial treasury is granted. Their decrees are called *posturas*, and the penalties imposed by them are enforced by the justices of peace. Their enactments can be annulled by the provincial legislative assembly.

The *judicial* power is independent; the judges hold their offices for life, and cannot lose them except by a condemnatory sentence. They are, however, responsible for any abuse of authority, and may be summoned before a supreme court of judicial ministers. In criminal cases all proceedings are public after the indictment. In civil cases arbitrators may be appointed, whose decisions are without appeal, and no civil lawsuit can be carried on without previous declaration that conciliatory means were tried in vain.

The constitution guarantees the inviolability of the liberty, safety, and property of Brazilian citizens, and of their civil

and political rights. Individual liberty is subject only to law, and in the same way liberty of thought and of the press are guaranteed. No one may be persecuted on account of religious belief, and every kind of labour or industry is free which does not interfere with public well-being. No one can be arrested without written orders from lawful authority.

litical d other isions.

For purposes of election the empire is divided into *districts*, each of which elects a fixed number of deputies for the general and provincial assemblies. These are again divided into colleges and parish assemblies. There are 46 electoral districts, 408 colleges, and 1451 parish assemblies. For administrative purposes the Brazilian territory is separated into 20 *provinces*, comprising 642 municipalities, including that of the capital; from various causes the number of municipalities is fluctuating. The ecclesiastical jurisdiction is exercised in 12 *dioceses*, one of which, that of São Salvador, comprehending the province of Bahia and Sergipe, is a metropolitan archbishopric. The whole of the dioceses are divided into 1473 parishes and 28 curacies. The diocese of São Salvador is the seat of a metropolitan court of appeal (Relaçao), composed of judges of appeal (*desembargadores*), who decide clerical matters finally. The diocese of São Sebastião comprises the municipality of Rio de Janeiro, its province, those of Espiritu Santo and Sta. Catharina, and the eastern side of Minas Geraes. The provinces of Alagôas, Pernambuco, Parahyba, and Rio Grande do Norte form the bishopric of Olinda; Maranhão and Piauhy the bishopric of the former name; Pará and Amazonas the diocese of Belem do Pará. The diocese of São Paulo includes that province, Paraná, and southern Minas Geraes; that of Goyaz its province and western Minas; the remainder of Minas forms the bishoprics of Marianna in the central, and of Diamantina in the northern part of the province. The diocese of Cuyabá consists of the province of Matto Grosso. The provinces of São Pedro do Rio Grande do Sul and of Ceará correspond to their respective bishoprics.

The judicial division of the empire is into eleven districts, each having a court of appeal competent to try all questions affecting the judges and military commanders. From the sentences of these courts there is but one appeal to a supreme court of justice, the members of which are denominated ministers, and by the constitution are counsellors to the emperor: this highest court takes cognizance of offences or errors committed by its ministers, by the judges of appeal, or by archbishops or bishops in non-ecclesiastical matters.

The districts of the Courts of Appeal are groups of provinces as follows:—

Pará and Amazonas	with the seat at	Belém.
Maranhão and Piauhy	,,	S. Luiz do Maranhão.
Ceará and Rio Grande do Norte......	,,	Fortaleza.
Pernambuco, Parahyba, and Alagoas	,,	Recife.
Bahia and Sergipe	,,	S. Salvador.
Rio and Espiritu Santo	,,	Rio de Janeiro.
S. Paulo and Paraná	,,	S. Paulo.
Rio Grande do Sul and Sta. Catharina	,,	Porto Alegre.
Minas Geraes	,,	Ouro Preto.
Matto Grosso	,,	Cuyabá.
Goyaz	,,	Goyaz.

Causes which do not ascend above a certain value, determined by law, are judged by *juizes de direito* within certain minor territorial limits, termed *comarcas*, again divided into *termos* or boroughs, which may include one or more municipalities, each of which has a municipal judge

The civil laws, originally the same with those of Portugal, have been greatly modified by a number of new ones A criminal code was organized in 1830 on the principles of Jeremy Bentham, and is considered very perfect and clear. The new form of procedure, and the new organization of justices, is embodied in a code decreed in 1832. Finally, a new code of commerce, nearly copied from that of France was decreed in 1850.

Finan

To carry on the war of the Independence, and to crush a subsequent revolution in the northern provinces, the Government contracted two loans in 1824–5, of the nominal amount of £3,686,200; and on the recognition of its independence by Portugal in 1825, it undertook the liability of a loan of £1,500,000. The war with Buenos Ayres, and the assistance rendered by Dom Pedro to the constitutional party of Portugal, led to two farther loans in 1829, of the nominal amount of £769,200. Internal difficulties in 1839 compelled the regency to contract another loan of the nominal amount of £411,200. The dissensions in Portugal caused a temporary suspension in the payment of the dividends on the Portuguese loan, and in 1842, £732,600 stock were delivered to the Portuguese agents in settlement of this claim. The debt contracted and assumed by Brazil between 1823 and 1843, therefore, amounted to £7,099,200 nominal; and throughout all its difficulties and embarrassments the Imperial Government punctually and honourably provided for the dividends as they became due.

By the renewal in 1844 of the sinking fund, the operation of which had been suspended since 1828, the Portuguese and other loans were becoming gradually reduced. The long war with Paraguay from 1864 to 1870, however, very considerably augmented the public debt, costing the empire more than 460,000 contos of reis, or nearly £52,000,000. The public debt is now divided into the consolidated foreign and internal debts, and the floating debt. The foreign debt proceeds from loans negotiated in the London Exchange in 1865, 1871, and 1875; the internal debt from policies authorized in 1827, but mainly from a home loan of 1868. The floating debt consists of the small remaining portion of that contracted previously to 1827, of loans borrowed from various internal sources, of exchequer bills, and paper money. Under these heads the debt of the empire was officially stated on the 31st of March 1875 as follows:—

External Debt	(at 5 per cent.	interest),	177,166 : 222	contos.
Internal	,,	,,	285,592 : 200	,,
Floating	,,	,,	201,980 : 973	,,
		Total Debt,	664,739 : 395=£74,783,000.	

(177,166 : 222=177,166 contos, 222 milreis; a conto or million of reis, gold=£112, 10s., or £1 = 8·890 milreis. 1 milreis=2s. 3d. The financial accounts are kept in *paper* reis, of depreciated value, in proportion varying from 194 to 214 reis paper to 100 reis gold.)

For a few years previously to the declaration of the emperor's majority, the imperial expenditure had not been largely in excess of the revenue, and in 1836–37, the deficit only amounted to £53,600; but in 1840–41, the year of the emperor's majority, it rose to £408,000, and in consequence of a revolution in Rio Grande do Sul it went on increasing till in 1845 it had reached nearly treble that sum. But before 1850 the deficiency had not only been made good, but a large surplus began to accumulate, which remained at about an annual sum of £400,000 after 1853. On the outbreak of the war in 1864, increased taxation was necessary to enable the exchequer to meet the extraordinary expenses, but on the close of the ministerial accounts for 1870–71, a surplus of upwards of £900,000 remained. In amount the revenues of the empire have progressively ascended from £1,380,000 in 1837 to upwards of £6,000,000.

The financial account of the year 1872–73, presented to the Chambers in May 1875, was as follows:—

Revenue.

Customs	£3,390,800
Taxes on Shipping	32,000
Export Duties	1,087,700
Railways	390,900
Posts	47,700
Telegraphs....................................	7,700
Stamps	227,000
Inland Taxes	756,000
Extraordinary receipts from bonds, issue of paper money, and deposits....	281,800
Carry forward	£6,221,600

Brought forward	£6,221,600
Fund for emancipation of slaves	86,200
Total state revenue 112,131 : 104 contos paper,[1] or	£6,307,800
Provincial receipts	1,210,000
Municipal receipts	256,000
Total (138,195 : 180 contos)	£7,773,800

Expenditure.

Home Department	£405,800
Justice	224,700
Foreign Affairs	58,900
Marine	1,006,600
War	1,358,300
Finances	2,375,000
Commerce	1,426,000
Total (121,874 : 462 contos)	£6,855,300

In the Budget for 1876–77 the receipts are estimated at 107,133 : 070 contos or £6,026,200 ; the expenditure at 105,378 : 914 contos or £5,927,800.

There are twenty-three custom houses, the amount of duties collected being largest in that of the capital, next in order those of Pernambuco, Bahia, and Pará.

The effective strength of the army and navy is every year fixed by the general legislative assembly, upon the data furnished by the ministers of the two departments. The army was originally organized on the principles established by Marshal Beresford when in the service of Portugal. It is principally from the northern provinces that the infantry is recruited, and from the southern that the best cavalry is obtained. A board, presided over by H. R. H. the Comte d'Eu, marshal of the army, is charged with the reformation of military legislation, and has been in session for some years. The actual army is thus composed, on a peace footing:—

a. Special corps, staff engineers and sanitary corps	427
b. Infantry, 21 battalions	9,864
c. Cavalry, 5 regiments and 2 battalions	2,484
d. Artillery, 3 regiments and 4 batteries, with 1 battalion of engineers	3,280
e. A division stationed in Paraguay, of various arms	1,894
	17,949

On a war footing the army is raised to 32,000 men.

Besides the regular army there is a national guard, which was organized in 1831, and comprised nearly 750,000 men in the latest returns, in cavalry, artillery, infantry, and reserve. This force has been disbanded for the present, to be re-organized on the completion of the census begun in 1872.

The police service of the empire is performed by city guards under military organization, under the provincial legislatures. The provinces of Pará, Pernambuco, Bahia, Rio Grande do Sul, and Matto Grosso possess military arsenals, recently reorganized. Military colonies for disciplinary or penitentiary objects, and also for protection of the frontiers, are dotted round the outskirts of the empire.

The navy is under the control of the minister of marine, assisted by a naval council instituted in 1855, organized after the plan of the French admiralty. There are six arsenals, and a pyrotechnical laboratory was established near Rio in 1868

The navy is principally manned by civilized aborigines and negroes, organized in bodies called imperial sailors, with a certain military discipline. The aborigines have a peculiar aptitude for a maritime life. Officers destined for the Brazilian navy receive a suitable education in the naval school of Rio, and for some years the Government introduced the practice of sending the more apt scholars to serve in the British, French, and American navies. In this way a body of efficient naval officers has been formed.

In 1875 the naval force was thus constituted:—

	Number	Guns
a. Steam-vessels—		
Armour-plated ships	19	73
Frigate	1	12
Corvettes	8	61
Gun-boats	23	47
Transports	7	
b. Sailing-vessels—		
Corvette	1	22
Sloops and smaller vessels	2	15
	61	230

These vessels were manned by 4136 seamen, including gunners and marines. One armoured vessel and four corvettes were on the stocks in 1875.

The Roman Catholic is the established religion of the empire. All other forms of worship are tolerated, but may only be practised privately. Dissenters enjoy all political and civil rights, with the sole exception of being elected into the chamber of deputies. The peculiarity of the ecclesiastical organization of the Brazilian church is, that the clergy do not receive the tithes. As a conquest of the military and religious order of Christ, all the churches of Brazil belonged from the beginning to that order, whose grand-master appointed the bishops, and submitted them directly to the approbation of the Pope. The order became so powerful that the king obtained the union of the grand-mastership to the crown, and so disposed of all the livings and other benefices of the order, and paid from his treasury the salaries of the clergy, receiving the tithes from the people as a civil tax. The tithes were afterwards abolished as oppressive. This organization is still recognized by the Holy See, and in the capacity of grand-master of the order of Christ the emperor appoints all the bishops and other ecclesiastical functionaries. There are convents of Franciscans, Carmelites, and Benedictines. These are very rich, and generally very learned men, who are usefully employed in teaching the sciences. They pay double annual taxes as a compensation to the treasury for not paying taxes upon transfers of property, as theirs is not transferable.

Primary and public schools, supported by the state through the provincial and municipal legislatures, for gratuitous instruction, have been established throughout the empire, under the general control of the ministry of the interior. In some of the provinces instruction has been made obligatory. Besides these, in which the teaching is limited to moral and religious instruction, reading and writing, the elements of grammar and arithmetic, there is a second or higher order of schools in most of the provinces, either public or private, in which such subjects as the elements of history and geography, especially that of Brazil, the principles of the physical sciences, elementary mathematics, drawing, Portuguese, French, and English are added. The Dom Pedro II. Imperial College of the capital has twenty-two professors, and provides a course of study of seven years, at the termination of which a degree of B.A. may be gained. Each diocese has a seminary for theological instruction, and these, with the exception of that of S. José in the capital, are subsidized by Government. Military training is under the care of the war department, and is carried on in preparatory and regimental schools, and further in military academies in the capital and in Rio Grande do Sul. A practical school of gunnery is established in the Campo Grande, near the capital; a central college with eleven professors also educates in the higher branches of military science and engineering.

An imperial astronomical observatory has been appended to the central college for the instruction of observers, and the recording of astronomical and meteorological phenomena. There is also a state observatory in Pernambuco. The naval college is established on board a war vessel,—the cadets being drafted to it from a preparatory naval

[1] Assumed to be at 200 paper for 100 gold.

school. A practical school of artillery is attached, and naval construction is taught in some of the higher national schools; but students are also sent to the best European navy yards. There are two faculties of medicine, one at Rio de Janeiro, and another at Bahia, each having a curriculum of six years, and conferring degrees. The faculties of law are seated at São Paulo and Recife in Pernambuco. An institute of commercial instruction is presided over by a Government commissioner in Rio. Other remarkable institutions are those for the education of the blind in Rio, and a deaf and dumb institute. An academy of fine arts is established, with schools, in Rio, as well as a conservatorium of music. A national museum of natural history was created in Rio in 1817, and is the most important of South America. Others of like character have been founded in Pará, in Ouro Preto, and in Ceará. The national public library in Rio is the most important establishment of its kind, having more than 100,000 volumes on all subjects. Extensive libraries are also attached to all the colleges and academies; and popular libraries have been created in each of the provincial capitals.

The press is represented by six daily newspapers in the capital, of which the *Diario do Rio* is the oldest, having been founded in 1817. The provincial towns together have nearly 200 newspapers.

The most important of the scientific societies of the empire is the Historical, Geographical, and Ethnographical Institute of Brazil, founded in 1838. There are besides this twenty larger scientific associations in Rio and the provincial capitals. With all these appliances, however, owing to the immense territory over which the population is scattered, the spread of instruction is exceedingly difficult, and the grossest ignorance yet abounds in the interior of almost every province.

It is obvious, from the insufficient establishments for general education, that the intellectual development of individuals must have been for a long period achieved in a great measure by unaided exertions. Now things are better, but in the more thinly inhabited districts devotion to such pursuits must not be expected in men exclusively occupied in procuring subsistence and securing self-defence. Even where the population is more dense, a lazy feeling of animal comfort represses the exertions of the majority. It is among the more aspiring class, who aim at the learned professions or state employment, and who are consequently obliged to cultivate their minds, that we must look for that attachment to intellectual pursuits which is rarely acquired except from habit. In the theological seminaries, established at the seat of each bishop, little more was inculcated than a knowledge of the classics, an outworn scholastic system of logic, and a knowledge of the routine duties of a priest. The schools of medicine in Rio Janeiro and in Bahia, from the attention bestowed upon practical surgery and anatomy, have done more to awaken the mind. The situations under Government requiring a certain proficiency in practical mathematics and natural history have also diffused a knowledge of and a taste for these pursuits. The number of foreign engineers and naturalists encouraged to settle in Brazil has rendered the natives in some measure acquainted with all that has been of late achieved in Europe in the mathematical and experimental sciences.

In parliament and by the press the most delicate political questions have been discussed with success, and the progress of the Government and of legislation evinces a certain administrative foresight and prudence rarely displayed by other new states.

The Brazilians who frequent the university of Coimbra in Portugal often distinguish themselves among their fellow-students; and notwithstanding the difficulties they have to contend against, not unfrequently rise to the highest offices of the state.

Literature.

The most remarkable writers in the Portuguese language on political economy and commercial law were Couttinho, bishop of Pernambuco, and Silva Lisboa, afterwards Viscount de Cayron, a senator of the empire, both Brazilians. Among historians the Brazilian Rocha Pita is distinguished, and Moraes the lexicographer of the Portuguese language belonged to Pernambuco. Portugal is poor in dramatic literature, but one of her most distinguished comic poets was the Brazilian Silva, who afterwards fell a victim to the inquisition of Lisbon. In epic poetry, on the other hand, Portuguese literature is rich. Brazil claims the authorship of two of its most beautiful poems of this class, the *Caramuru* of Durão, and the *Uruguay* of Gama. The best of the minor poets is Gonzaga, whose collection of lyrics is well known under the title of *Marilia de Dircêo.* Little inferior to him is Souza Caldas, whose translation of the Psalms denotes a talent of the first order. Claudio, Avarenga, Gregorio de Mattos, Euzebio de Mattos, Gusmão, in former times; and more recently, Odorico, Mendes, Borges de Barros, Domingos Magalhaës, Marquis of Paranaguá, A. de Macedo, Porto-Alegre, Barbosa, and others are well worthy of notice as lyric poets.

Religious eloquence was formerly much cultivated in Brazil, and Vieira is one of the most original and eloquent preachers known. In more recent times Antonio Carlos and Montalverne deserve particular notice. In the natural sciences Frei Leandro, Arruda, Camara, and José Bonifacio de Andrada are known for their works and discoveries.

Fine art.

In sacred music José Mauricio, a mulatto, left compositions of merit that were executed in the chapel of D. John VI.

The Brazilians have a natural taste for music, and an Italian theatre, maintained with but little interruption in Rio de Janeiro, has assisted in improving and refining this taste. The old-fashioned Brazilian instrument, which was a particular kind of guitar, has almost disappeared from the large cities, but is still frequently employed in the provinces to accompany the *modinhas* (romances) which are peculiar to Brazil, and which have a particular style.

The school of the fine arts of Rio de Janeiro has produced some good but no remarkable painters. Of late, however, the most promising artists have been annually sent to Italy at the public expense to prosecute their studies in that country.

National character.

The Brazilians are in general hospitable, generous, and charitable, endowed with great pride and vanity, and susceptibility of character, and are easily led away by flattery. The unlimited power they exercise over the African slaves, and the colonial system from which they have but a short time been freed, the imperfect religious education, the facility with which they can live in abundance at small cost, while the climate enables them to dispense with many things necessary in other countries, the enervating effects of the hot atmosphere, all combine to stimulate the qualities and vices which we must expect in this people.

There is in the Brazilian national character, with great mildness and generosity, a certain tendency to vindictiveness. Homicides for the sake of vengeance alone are proportionally as numerous in Brazil as in certain countries of Europe; while the crimes against property are much fewer. The greatest number of homicides, however, takes place in the most backward provinces of the centre and north.

The Roman Catholic religion predominates in Brazil, and although there are enlightened men among the clergy, a great number of the priests are ill educated, and the institution of celibacy keeps the members of the principal

families from entering the profession. Such is the want of priests that the Government finds itself obliged to send to Italy for them. Among educated classes the spirit of materialism of the French writers of the 18th century made great progress, but a considerable reaction has lately taken place. The lower classes, above all in the interior, are still deplorably superstitious.

In several of the provinces contentions have arisen of late years between the church and freemasonry, and the excommunication of the members of the craft and the closing of the churches to which they belonged have awakened religious discussions and agitations. The Jesuit priests were expelled from the province of Pernambuco in 1875, and the bishop of that diocese, tried before the lay tribunal, was condemned to fine and imprisonment.

Brazil is not specially a manufacturing country, and its national industries of mining (with smelting of the metals), collecting and polishing precious stones, and salt making, already referred to, with tanning and hide working, have the widest range. The state has, however, encouraged and in some cases subsidized special manufactures which were of value in developing the resources of the country. Among these seventeen foundries, manufacturing engines and agricultural implements, have supplied a great national want. The home hat factories of Brazil have now all but superseded the imported hats by their products. In almost every city there are manufactories of soap, oil, and candles, which are made, not only of stearine and tallow, but of wax, and in the north from the valuable Carnauba palm. Rum distilling is largely carried on in the sugar districts, and cigars are extensively made, especially at Bahia. Gold and silver smiths and jewel workers are foremost among the delicate handicraftsmen, and excel in their workmanship.

There are now two cotton-cloth factories in Rio, five in Bahia, two in Minas, and several in S. Paulo, and this branch of industry is extending.

Ship-building is diligently prosecuted in many of the ports, and Rio has launched several fine iron-clad vessels from the navy yard. A law passed in 1871 enabled Government to subsidize companies for the construction of more commodious docks, and these have been begun in Rio, Bahia, and Maranhão, at Santos in S. Paulo, and at Paranaguá in Paraná.

Whale-fishery is carried on to some small extent from the ports of Bahia and Sta. Catharina. The fine coastal fisheries are not yet taken advantage of to nearly their full power; on the other hand, large quantities of dried cod-fish are imported. On the upper Amazon and its tributaries a considerable quantity of oil is collected from the eggs of the turtle, and is sent down in earthen pots containing 50 to 60 lb weight each.

Jerked beef, an important article of general consumption, is chiefly prepared in the "Charqueadas" of Rio Grande do Sul.

The coastal and fluvial communications of the empire are maintained by eighteen lines of steam-vessels, which receive an annual subsidy from the state (amounting to £150,000 in 1875). A North American company, keeping up a regular traffic between the ports of Brazil and the United States, is also aided by Government. Besides these the ocean lines of large vessels from Britain, Germany, and France, touch regularly at the chief points in passing to the La Plata. Almost all the navigable rivers of Brazil have now their regular steam packets. The Amazon has been navigated by steam for nearly twenty years; and since the passing of the decree of September 1867, by which its waters were opened to the trading ships of all nations, direct commerce from foreign countries with the interior ports on its banks has begun to be developed.

Within recent times the construction of railroads has been progressing very rapidly under the Government and in private hands. In 1867 there were but six short lines working; in 1873 there were fifteen distinct railways. Three main trunk lines are being actively extended by the state: the first called the Dom Pedro II. line, passing from Rio de Janeiro to Minas Geraes, is being extended thence to the head of the navigation of the São Francisco, and is planned to reach the valley of the Tocantins and Pará; the second trunk line is designed to unite the navigation of the Amazon with that of the Paraguay, through the head of the valley of the Tocantins and Araguaya; the third line, already partly executed, beginning at Rio will pass through the capitals of S. Paulo and Paraná to Porto Alegre in Rio Grande do Sul. Many other lines have been begun or are projected under the superintendence of the provincial assemblies. The ordinary roads are in an exceedingly backward condition throughout the empire, and those which are more than rude tracks are of very small extent. A fine macadamized road, however, called the "Union and Industry," joins the capital with Minas Geraes, and others extend for short distances from the chief towns. There are also a few canals. It is but seventeen years since the first small line of telegraph was stretched in Brazil within the capital, but now a double line unites the maritime towns from Pernambuco to Rio Grande do Sul. Many other lines are being constructed, and in June 1874 submarine telegraphic cable was completed from Europe to the Brazilian ports.

The commerce of Brazil, despite the disadvantages against which it has had at various times to contend, has been on the whole uniformly progressive. These disadvantages consisted chiefly in the restrictions originally imposed on the young colony by the jealousy of the mother country, which refused to admit the Brazilian products except at certain stated seasons of the year. The exportation of native productions to the Old World was limited to the ports of Rio, Bahia, Olinda, and Paraiba. These restrictions continued in force long after analogous measures had been exploded in the commercial systems of other countries, and were not repealed till the beginning of the present century. In 1810, all the ports of Brazil were thrown open to British goods on the payment of duty at the rate of 15 per cent., and though this rate has been greatly increased by the tariff of 1844, the average annual value of manufactured goods imported into Brazil from Great Britain alone, chiefly cotton, iron, woollen, and linen goods, amounts to nearly £4,500,000.

The value of the imports and exports of Brazil in 1808 was estimated at £2260; it has gradually increased, with little fluctuation, till at the present time the annual value of trade is not less than £40,000,000. The trade of the empire is mainly with Great Britain (which sends more than a third of the imports, and receives a great share of the exports), France, the United States, Portugal, Germany, the Argentine Republic, and Belgium. In the order of their value the chief exports are coffee, hides, sugar, cotton, india-rubber, tobacco, yerba-mate, diamonds, and rum. Since 1853 the value of the exports from the country has in most years been somewhat in excess of that of the imports. The whole number of ships entering and leaving the Brazilian ports in recent years averages about 30,000.

(K. J.)

BRAZIL, Island of, and other imaginary islands in the Atlantic. For a long time before the discovery of America, the fancies of navigators or of cosmographers had scattered over the Atlantic a number of islands, either wholly imaginary, or so detached from the germ of truth which had suggested their existence as to represent no fact in nature. Several such islands are described in the Arabic geography of Edrisi (1153–54 A.D.), and if, passing over more than four hundred years, we take up an atlas of Münster or Mercator we shall find that the northern Atlantic, instead of presenting a vast blank as in our most recent charts, is almost as full of islands and shoals as the heaven is of stars. To our present category belongs the island of St Brandon, the supposed discovery of an Irish eremite of the 6th century, of whose voyage many wonders are related. Such also were *Antilia* and the *Island of the Seven Cities*, connected with another legend of uncertain date, which described this as the refuge of a body of Christians, who, in flight from the Saracen conquerors of the Peninsula, had, under the guidance of their seven bishops, committed themselves to the wide ocean; such were *Mayda* or *Asmaide*, the *Isla Verde*, or Green Isle (which the natives of the Hebrides still think they see beneath the western sun), but none more famous and recurrent than the *Isle of Brazil*. The name of this island connects itself with the red dye-woods known by that name in the Middle Ages, a name that possibly also may have been applied to other vegetable dyes, and so may descend from the *Insulæ Purpurariæ* of Pliny. Its first appearance on a map appears to be (*I. de Brazi*) in the Venetian portulano of Andrea di Bianco (1436), where it is found attached to one of the larger islands of the Azores. When this group became better known and was colonized, the island in question got the name of Terceira. And the conservative spirit of map-makers then sought a new position for that Island of Brazil which they found in the charts of their predecessors, and this island grew in (imaginary) importance and size. In time, better knowledge of the Atlantic showed that these must be exaggerated, but belief in the island's existence endured.

The conservative spirit just referred to has indeed preserved in some shape most of the names mentioned above. The name of the *Seven Cities* survives as applied to a volcanic district of the Island of St Michael's (Azores). *Antilia* and *St Brandon's Isle* were conspicuous on the maps which were probably in the hands of Columbus on his first western voyage. The latter name has disappeared indeed, but the former survives in a plural form, as applied to the West Indies (*Antilles*). So also it is probable that the familiar existence of "Brazil" as a geographical name led to its bestowal upon the vast continental region of South America, which was found to supply dye-woods kindred to those which the name properly denoted. The older memory, however, survived also, and the *Island* of Brazil retained its place in mid-ocean, some hundred miles to the west of Ireland, both in the traditions of the forecastle and in charts. In Purday's *General Chart of the Atlantic*, "corrected to 1830," we find the *Mayda* indeed noted as "very doubtful," but "*Isle Verte or Green Rock*" (44° 48′ N. lat., and 26°10′ W. long.) with the remark, "Existence lately confirmed;" and "*Brazil Rock* (high)," with no indication of doubt, in 51° 10′ N. lat., 15° 50′ W. long. In a chart of currents by the late Mr Findlay, dated 1853, these names appear again. But in his 12th edition of Purday's *Memoir Descriptive and Explanatory of the N. Atlantic Ocean* (1865), the existence of these islands is briefly discussed and rejected by Mr Findlay, with the intimation that their names would be entirely omitted in future editions.

Thus the official sepulture of the old tradition of the island of Brazil took place only eleven years before the date of this article (1876). And now the surface of the Atlantic, as represented in the latest Admiralty charts, shows between St Kilda and Bermuda, between Newfoundland and the Azores, but one point rising above the water, viz., the sugar loaf of *Rockall*, in 57° 35′ 52″ N. lat., 13° 42′ 21″ W. long. (H. Y.)

BRAZIL NUTS are the seeds of *Bertholletia excelsa* (*B. nobilis* of Miers), a gigantic tree belonging to the natural order *Lecythidaceæ*, which grows in the valleys of the Amazons and generally throughout tropical America. The tree attains an average height of 130 feet, having a smooth cylindrical trunk, with a diameter of 14 feet 50 feet from the ground, and branching at a height of about 100 feet. The lower portion of the trunk presents a buttressed aspect, owing to the upward extension of the roots in the form of thin prop-like walls surrounding the stem. The fruit of the tree is globular, with a diameter of 5 or 6 inches, and consists of a thick hard woody shell, within which are closely packed the seeds which constitute the so-called nuts of commerce. The seeds are triangular in form, having a hard woody testa enclosing the "kernel;" and of these each fruit contains from eighteen to twenty-five. The fruits as they ripen fall from their lofty position, and they are at the proper season annually collected and broken open by the Indians. From Para alone it is estimated that upwards of two and a half millions of fruits, equal to fifty millions of "nuts," are exported annually, in addition to the large quantities which leave other Brazilian harbours, and Demerara, Cayenne, &c. Brazil nuts are largely eaten; they also yield in the proportion of about 9 oz. to each pound of kernels a fine bland fluid oil, highly valued for use in cookery, and used by watchmakers and artists.

BRAZIL WOOD is one of several dye woods of commerce which come from the West Indies and South America, belonging to the genera *Cæsalpinia* and *Peltophorum* of the natural order *Leguminosæ*. The species to which the various woods belong have not been well determined, but commercially they are distinguished as Brazil wood, Nicaragua or Peach wood, Pernambuco wood, and Lima wood, each of which has a different commercial value, although the tinctorial principle they yield is similar. Commercial Brazil wood is imported for the use of dyers in billets of large size, and is a dense compact wood of a reddish brown colour, rather bright when freshly cut, but becoming dull on exposure. The colouring-matter of Brazil wood is freely soluble in water, and it is extracted for use by simple infusion or decoction of the coarsely-powdered wood. When freshly prepared the extract is of a yellowish tint; but by contact with the air, or the addition of an alkaline solution, it develops a brick red colour. A chemical principle, termed brazilin, has been isolated from Brazil wood. It crystallizes into hexagonal amber yellow crystals, which are soluble in water and alcohol. The solution when free of oxygen is colourless, but on the access of air it assumes first a yellow and thereafter a reddish yellow colour. With soda-ley it takes a brilliant deep carmine tint, which colour may be discharged by heating in a closed vessel with zinc dust, in which condition the solution is excessively sensitive to oxygen, the slightest exposure to air immediately giving a deep carmine. With tin mordants Brazil wood gives brilliant but fugitive steam reds in calico-printing; but on account of the loose nature of its dyes it is seldom used except as an adjunct to other colours. It is used to form lakes which are employed in tinting papers, staining paper-hangings, and for various other decorative purposes.

BRAZZA, the ancient *Brattia*, an island in the Adriatic, off the coast of Dalmatia, in the circle of Spalatro, and eight miles from that city. It has an area of 170 square miles, and a population of 15,500. The surface is rugged and mountainous, but is industriously cultivated, and its wine is accounted the best in Dalmatia. It produces also oil, figs, almonds, and saffron; but the corn crop scarcely supplies the wants of the inhabitants for three months. There are about twelve or thirteen hamlets in the island, the most important being San Pietro, Neresi, Bol, and Milnä.

BREAD. See Baking, vol. iii. p. 250.

BREAD-FRUIT. This most important food staple of the tropical islands in the Pacific Ocean is the fruit of

Artocarpus incisa (nat. ord. *Artocarpaceæ*). The tree attains a moderate height, has very large, acutely lobed, glossy leaves, the male flowers in spikes, and the female flowers in a dense head, which by consolidation of their fleshy carpels and receptacles form the fruit. The fruit is globular in shape, about the size of a melon, with a tuberculated or (in some varieties) nearly smooth surface. Many varieties of the tree are cultivated, the fruits of some ripening numerous seeds, which are eaten as chestnuts; but in the best kinds the seeds are aborted, and it is only these that are highly prized as vegetables. The tree is a native of the South Sea Islands, where its fruit occupies the important position that is held by cereals in temperate latitudes. The fruit, which on distinct varieties ripens at different periods, affording a nearly constant supply throughout the year, is gathered for use just before it ripens, when it is found to be gorged with starchy matter, to which its esculent value is due. It may be cooked and prepared for use in a great variety of ways, the common practice in the South Sea Islands being to bake it entire in hot embers, and scoop out the interior, which when properly cooked should have a soft smooth consistence, fibrous only towards the heart, with a taste which has been compared to that of boiled potatoes and sweet milk. Of this fruit Mr A. R. Wallace, in his *Malay Archipelago*, says,—"With meat and gravy it is a vegetable superior to anything I know either in temperate or tropical countries. With sugar, milk, butter, or treacle it is a delicious pudding, having a very slight and delicate but characteristic flavour, which, like that of good bread and potatoes, one never gets tired of." In the Pacific Islands the fruit is preserved for use by storing in pits, where the fruits ferment and resolve themselves into a mass similar in consistency to new cheese, in which state they emit an offensive odour; but after baking under hot stones they yield a pleasant and nutritious food. Another and more common method of preserving the fruit for use consists in cutting it into thin slices, which are dried in the sun. From such dried slices a flour may be prepared which is useful for the preparation of puddings, bread, and biscuits, or the slices may be baked and eaten without grinding. The tree yields other products of economic value, such as native cloth from the fibrous inner bark of young trees; the wood is used for canoes and articles of furniture; and a kind of glue and caulking material are obtained from the viscid milky juice which exudes from incisions made in the stem.

The bread-fruit is now found throughout the tropical regions of both hemispheres, and its first introduction into the West Indies is connected with the famous mutiny of the "Bounty," and the remarkable history of a small company of the mutineers at Pitcairn Island. Attention was directed to the fruit in 1688 by Captain Dampier, and later by Captain Cook, who recommended its transplantation to the West Indian colonies. In 1787 the "Bounty" was fitted out under command of Lieutenant Bligh to proceed to Tahiti to carry plants thence to the West Indian Islands; and it was after the cargo had been secured and the vessel was on her way that the mutiny broke out, and Lieutenant Bligh and some of his crew were turned adrift in a small boat in the open sea. The mutineers returned with the vessel to Tahiti, whence a number of them, with a few native men and women, sailed to the desolate and lone islet of Pitcairn. Lieutenant Bligh ultimately reached England, and was again commissioned to undertake the work of transplanting the plants, which in the year 1792-3 he successfully accomplished.

A somewhat similar but much inferior fruit is produced by an allied species, the Jack or Jak, *Artocarpus integrifolia*, growing in South India, Ceylon, and the Eastern Archipelago. This tree is chiefly valuable on account of its timber, which has a grain very similar to mahogany, and although at first light coloured it gradually assumes much of the appearance of that wood.

BREAKWATERS differ from piers in their not being necessarily adapted for commercial purposes. They do not, therefore, require to have roadways for the accommodation of traffic, or parapets for keeping water or spray from passing over them. Breakwaters are artificial structures consisting generally of stones or blocks of concrete, built or deposited in deep water. Their object is to tranquillize those portions of the sea which they cover, and which thus become sheltered anchorages. They may be divided into three classes:—(1.) Vertical or nearly vertical structures of built masonry for arresting the onshore progress of the waves, and for either reflecting them seawards or deflecting them laterally. (2.) Sloping structures of rubble stones dropped into the sea from timber stages or floating barges, and hence termed *pierres perdues*, having a sloping face on each side, termed a *talus* or *glacis*. These slopes, which, after the blocks have been consolidated, are generally protected above low water by stones set closely together, called *pitching*, are the angles of repose assumed by the loose blocks under the influence of the waves, and vary in steepness from above high water to below low water, where the force of waves is least. They vary from about 1 foot horizontal to 1 foot vertical to 7 feet horizontal to 1 foot vertical. (3.) What may be termed composite breakwaters are partly sloping and partly vertical, and act by causing the waves to break, and also by partially reflecting them seawards or deflecting them laterally. The new breakwater at Aberdeen and the Dover Admiralty pier, which acts also as a breakwater, are examples of the *first* class. Plymouth breakwater, which rises with a general sea-slope of from 2 to 5 horizontal to 1 vertical to a height of 23 feet above high water, is an example of the *second* class. Cherbourg, which slopes from low water to high water, above which level there is a vertical barrier rising to 12½ feet above high water, is an example of the *third* class. Breakwaters, though passive, are nevertheless real agents by which work is done in combating the waves in one or other of the three modes which have been defined. For further information regarding the design of breakwaters and the details of their construction see HARBOURS.

BRECHIN, a parliamentary burgh of Scotland in the county of Forfar, 7½ miles W. of Montrose, and connected by a branch-line with the Caledonian Railway. It is situated on an abrupt declivity on the north bank of the River South Esk, here crossed by a stone bridge of very early date. The principal buildings comprise the parish church (with steeple and spire 128 feet high)—forming part of an ancient and uncompleted cathedral, of Gothic architecture, which has been injured by modern alterations. several other churches, a town-house, the public and Smith's school, a mechanics' institute, and an infirmary. The diocesan library hall of the Episcopal church contains an extensive and valuable collection of books, many of them presented by Bishop Abernethy-Drummond, and about 2000 by the late Bishop Forbes, who erected the building. Some ruins remain in the "vennel" of the Maison Dieu, or *hospitium*, founded by William of Brechin in 1256. The most remarkable edifice, however, is the round tower, situated in the churchyard near the cathedral. This tower is similar to those so common in Ireland, but in Scotland is only rivalled by the tower at Abernethy. Like similar buildings, it contains no stair, and the only access to the top is by means of ladders placed on wooden floors, which rest on circular stone projections within the tower. The height from the ground to the roof is 86¾ feet, the inner diameter within a few feet of the bottom is 8 feet, and the thickness of the wall at that part about 4 feet; the circum-

ference is very near 50 feet; the inner diameter at top is 6 feet 7 inches, the thickness of the wall 2 feet 10 inches, and the circumference 38 feet 8 inches. These proportions give the building a high degree of elegance. The top is roofed with an octagonal spire 18 feet high, which makes the whole height of the building 101 feet 9 inches. Brechin Castle, which was a place of some strength during the Wars of the Independence, now a seat of Lord Dalhousie, lies a little to the south of the town. There is a public park near the town, and two large nurseries. There are three extensive power-loom linen factories (one of them a building of much taste), two bleach-fields, two distilleries, a brewery, and a paper-work; and extensive freestone quarries exist in the neighbourhood. The town is lighted with gas, and an ample supply of water has been introduced at great expense. Weekly markets are held on Tuesdays; and statutory fairs for horses, cattle, and sheep are held at Trinity Muir, about a mile north of the town. Brechin unites with Montrose, Arbroath, Forfar, and Bervie in returning one member to parliament. The population of the parliamentary burgh was in 1871, 7959; and of the royal burgh, 5083.

Brechin is a place of great antiquity, and was chosen by the Culdees as the site of one of their convents. It is said to have been burned by the Danes in 1012. In 1150 it was erected into a bishopric by David I. In 1572 James VI. gave a grant for founding a hospital in the burgh, which still supplies the magistrates with funds for charity. In 1645 the town and castle were harried by the marquis of Montrose. Maitland the topographer and Gillies the historian of Greece were natives of Brechin.

BRECON, or Brecknockshire, an inland county in South Wales. Its greatest length from south to north is about 53 miles, and its greatest breadth from east to west about 46 miles. It possesses an area of 719 square miles, or 460,158 acres, and is thus the fourth largest county in Wales. It is said to have derived its name from Brychan, a Welsh prince, who flourished in the fifth century.

The Old Red Sandstone is the principal geological formation in this county, and occupies the whole of the central portion from east to west. Along the southern boundary there extends a narrow belt of carboniferous limestone, millstone grit ("farewell rock" of the miners), and the outcrop of the coal beds,—together forming the northern rim of the coal measures in the great South Wales coal-field. At Clydach in Llanelly, Brynmawr, Hirwaun, and a few other places on the south-eastern border of the county, there are extensive iron-works. The narrow projecting part of the county to the north, lying between Radnor and Cardigan, is occupied by the Upper and Lower Silurian beds; and there is a somewhat singular narrow peninsula of the former projecting into the Red Sandstone for a distance of ten miles, in a S.W. direction, and terminating at about five miles north of the town of Brecon. A belt of limestone extends from the town of Hay on the east, and passing in a S.W. direction through the town of Brecon, terminates at the Brecknockshire Van. A prominent band extends along the border of the Old Red Sandstone on the N.W., where it joins the Silurian beds.

The general aspect of the county is mountainous, and the scenery is marked by beauty and grandeur. A chain of the loftiest mountains in South Wales completely encircles the south, composed in the east of the Black Mountains, 2545 feet in height, and the curious Sugar Loaf rising to the height of 1760 feet. On the west of Brecknockshire are the Van and Talsarn mountains 2596 feet, and Mount Capellante 2394 feet in height; while the centre of the crescent is occupied by the masses of the Brecknockshire Beacons, the highest point of which, Cader Arthur, or Arthur's Chair, attains an altitude of 2910 feet. In the north, a range of barren hills, called Mynydd Bwlch Groes at the most westerly end and Mynydd Epynt towards the east, enters the boundary of the county at a short distance from Llandovery in Carmarthenshire, and extending in a N.E. direction, terminates near Builth.

Of the valleys the most distinguished for beauty is that of the Usk, stretching from east to west, and dividing the county into two nearly equal portions. The Wye is the chief river, and forms the boundary on the N. and N.E. from Rhayader to Hay, a distance of upwards of twenty miles; while the Towy, the Afon Claerwen, and the Elan separate the county from Cardigan and Radnor on the N.W. and N. The Usk rises in the Carmarthenshire Van on the west, and flowing in a direction nearly due east through the centre of the county, collects the waters from the range of the Beacons in the south, and from Mynydd Bwlch Groes and Mynydd Epynt in the north, by means of numerous smaller streams (of which the Tarell and the Honddu are the most important), and enters the county of Monmouth near Abergaveny. The Taff, the Hepstau, and the Tawe, all rise on the south of the Beacon range, and passing through Glamorganshire, flow into the British Channel.

Llyn Safaddu, Llangorse Lake, or Brecknioc Mere, the largest lake in South Wales, is situated at the foot of the Black Mountains, and within the county. It covers an extent of nearly 1800 acres, and is about two miles long by one mile broad. Upon an artificial island in the lake traces of habitations raised on piles have lately been discovered, together with the bones of red deer, wild boar, and *Bos longifrons*. Tradition affirms that beneath the lake is a submerged town, which has been rashly identified with the Roman station *Loventium*.

The climate is moist, but temperate and salubrious; and the soil of the valleys, often consisting of rich alluvial deposits, is very fertile. The cultivated crops consist of wheat, oats, barley, rye, turnips, pease, potatoes, and vetches; of these the greater part is consumed within the county. The uplands are chiefly in pasture, and are stocked with sheep, cattle, and ponies, which with wool, butter, and oak-bark, form the staple of a considerable trade with the adjoining English counties, and with the iron districts lying to the south. The farms are generally small, but are well cultivated in the lower parts of the county. The highland occupiers are a very humble, hard-working class of men. It is calculated that about two-thirds of the lands in the county are enclosed.

Breconshire is intersected by the Mid Wales, Brecon, and Merthyr Railway, and a branch of the London and North-Western, by means of which there is ready com munication with all parts of the kingdom.

The principal towns are Brecon, Builth, Crickhowel, and Hay. The county returns one member to parliament, and has done so since 1536. The political influence is chiefly in the hands of Lord Tredegar and Sir Joseph Bailey. Constituency in 1875, 3574. Rents in the valley of the Usk and around Brecon are high, but on the mountain lands very low; it would be deceptive to give an average per acre. The annual value of real property paying income-tax is £316,208. The population of the county by the last census was 59,901, giving an average of 83 persons to a square mile, or 7·68 acres to each person. Of the total number 29,928 were males, and 29,973 females. The number of inhabited houses was 12,617, giving an average of 17·5 inhabited houses to a square mile, and 4·7 persons to each house. The following returns show an increase of population amounting to 34 per cent. during the last fifty years:—

1821	43,826
1831	47,763
1841	55,603
1851	61,474
1861	61,627
1871	59,901

The Welsh language is still that of the peasantry and middle class, and the members of the Church of England are largely out-numbered by the Baptists, Calvinistic Methodists, and Independents.

Brecknockshire formed part of the territory of the Silures, and its occupation by the Romans could never have been very complete. After their expulsion the district (*Brycheiniog*) was ruled by native princes and was the scene of many a border struggle. Many of the castles which are scattered over its eastern border had their origin at this period; and some of them may be regarded as advanced posts erected by the English during the wars which preceded the formation of Offa's Dyke. Subsequently, when Bernard de Newmarch and his Norman followers obtained possession of the country, they were converted into regular fortresses, by which the neighbourhood was kept in awe, and the mountain passes defended. The district between Brecon and Builth was the scene of the last struggle between the English and Llewelyn in 1282, when the Welsh chieftain was defeated and slain. Since that date Breconshire has not been associated with any important historical events, unless we include among them the raids of Owen Glyndwr. It formed part of the Welsh Marches until their union with England in 1532. Among the eminent natives of the county may be mentioned Sir David Gam (Shakspeare's Fluellen), who lost his life at Agincourt while defending Henry V.; the ill-fated Henry Stafford, duke of Buckingham; John Penry ("Martin Marprelate"); Henry Vaughan, the poet; Dr Hugh Price, founder of Jesus College, Oxford; Thomas Howel, bishop of Bristol (less known than his brother, the letter writer); Theo. Jones, historian of the county; and Mrs Siddons.

Brecon, or Brecknock, the capital of the county of the same name, a market and borough town, 145 miles N. by W. from London, picturesquely situated in a fine open valley, at the confluence of the Honddu and Tarell with the Usk, and nearly in the centre of the county. It is supposed to occupy the site of the Roman station *Bannium*, but it is more probable that it was partly constructed with materials drawn from that spot, which lies to the W. of the present town, on the Via Julia Montana. There are three main streets, with several smaller ones. The houses are for the most part constructed of stone, and are generally well built. Brecon has a fine cruciform church (Early English in style), which has been restored by Sir Gilbert Scott. There are two other churches, and two Independent, two Baptist, and one Calvinistic Methodist chapel. The corporation consists of a mayor, recorder, four aldermen, and twelve councillors. The borough has returned one member to parliament since 1536. Constituency in 1875, 813. The assessed taxes yield annually £1259, and the annual value of real property paying income-tax is £24,941. There are weekly markets, and several fairs in the course of the year. The quarter sessions and assizes are held here. Brecon has a foundation called the College of Christ Church, of which the bishop of St David's is *ex officio* dean, but after the death of its present officers its revenues will devolve to the ecclesiastical commissioners and be appropriated to ecclesiastical uses. The ruins of the ancient castle are enclosed in the beautiful grounds of the Castle Hotel, and though unimportant in themselves, derive an interest from their connection with the Fitzwalters, de Braoses, de Bohuns, and Staffords, successive lords of Brecon. The principal fragment now remaining is Ely Tower, so called from its having formed the prison of Morton, bishop of Ely, where he concerted with his custodian, Henry Stafford, duke of Buckingham, the dethronement of Richard III., and the union of the houses of York and Lancaster. There are some fine Roman and other remains in the immediate vicinity. Population of municipality in 1871, 5845; inhabited houses, 1172.

BREDA, a town of Holland in the province of North Brabant, and capital of a circle, is situated in a marshy plain on the Merck, 24 miles S.W. of Bois-le-Duc, and 30 N.N.E. of Antwerp. It is strongly fortified and defended by a citadel (rebuilt by William III. of England), and the surrounding district may be laid under water when required. The town is well built, with wide and well-paved streets, is intersected by several canals, and has a fine quay, a town-hall, an arsenal, an observatory, an orphan asylum, a cathedral, and several Roman Catholic and Protestant churches, one of the latter having a spire 362 feet in height. It has also a Latin school and a military academy, and manufactures of linen and woollen goods, carpets, hats, beer, and musical instruments. Population (1869), 14,172.

Breda obtained municipal rights in 1252 from Henry, but was not surrounded with walls till 1534. The old castle, which had been built in 1350 by Jan Van Polanen, was restored about the same time. It was the residence of Charles II. in his exile. In 1696 William Prince of Orange and king of England caused the erection of the new castle, which was regarded as one of the finest buildings of the period. This is now the seat of the military academy. The town was captured by the Spaniards in 1581, by Maurice of Orange in 1590; again by the Spaniards, under Spinola, in 1625; and by Henry of Orange in 1637. It was finally ceded to Holland by the treaty of Westphalia in 1648. During the wars of the French Revolution it was taken by Dumouriez in 1793, and again by Pichegru in 1795. Much of its celebrity is due to the various political congresses of which it has been the scene. In 1566 the nobles of the Netherlands formed there the league known as the Compromise; in 1575 a conference was held between the ambassadors of Spain and those of the United Provinces; in 1667 a peace was signed between England, Holland, France, and Denmark; and in 1746–7 the representatives of the same powers met in the town to discuss the terms of another treaty.

BREDA, Jan Van, a Dutch painter, was the son of Alexander Van Breda, an artist of considerable merit, and was born at Antwerp in 1683. He imitated the style of Wouvermans and Breughel with such dexterity, that even connoisseurs are often unable to distinguish his copies of their pictures from the originals. He visited England, where he was so well employed, that in a few years he was able to retire to his native country with a competency. The earl of Derwentwater was one of his chief patrons. He died at Antwerp in 1750.

BREDOW, Gabriel Gottfried, a German historian and professor in the university of Breslau, was born at Berlin in 1773. He is known in England by his *Manual of Ancient History*, which was translated into English in 1827; *Researches on History, Geography, and Chronology*; and his valuable *Historical Tables*, which come down to 1811. This last work was translated into English by Major J. Bell, who continued the tables down to 1820, and produced a popular and very useful work. Bredow died in 1814.

BREEDS AND BREEDING.[1] The word breeds is usually applied to the varieties of domesticated *animals* only, but since the phenomena presented under cultivation by all classes of organisms are entirely similar in character, and since, moreover, much of our knowledge on the subject has been gained from botany and horticulture, we shall include, under the one term breeds, the varieties of domestic animals and of cultivated plants. The natural and simple definition of breeding would be the art by which breeds are produced. But here the objection arises, that in this definition too much is assumed. It may be argued that our domesticated animals and plants are each

[1] Many of the facts and arguments contained in the present article are taken from Mr Darwin's work, *The Variation of Animals and Plants under Domestication*, 1868, and 2d. ed. 1875; and in most instances it has not been considered necessary to give the references.

identical with a wild prototype either living or extinct, and that man has merely deprived them of liberty and regulated their environment and propagation in the manner most advantageous to each kind. At the present day, when the whole range of biological thought is so largely permeated by the principles of the doctrine of evolution, this objection will probably not be advanced. Yet, when it is remembered that such an authority as Col. Hamilton Smith held the belief that each breed of dog had its wild prototype, it appears necessary to modify the definition above given. Let it be said that the art of breeding consists in changing the conditions of life and regulating the reproduction of animals and plants.

Since a breed is a domestic variety, it implies the existence of a group of individuals marked off from their congeners by the possession of certain characters which are transmitted to their offspring. It is this *transmission* of peculiarities which is the essential characteristic of a breed; for any collection of domesticated organisms could be divided into groups of individuals distinguished by certain points, but such groups would not necessarily form breeds. It is evident, then, that the law of heredity which asserts that "like begets like" must hold good, or the existence of breeds will be an impossibility. Again, if it were absolutely true that like begets like, that is, if the offspring were in all cases identical with the parent, it is evident that neither by man's interference, nor by the operation of nature, could a breed or race arise. It seems, then, that were it not in the nature of all organic beings to reproduce their kind in the manner formulated in the principle of heredity, and were it not for the continuous slight infringement of it expressed by the principle of variability, breeds could not have arisen. It is therefore necessary to examine these two principles as part of the subject under consideration.

Whatever views we may entertain respecting the origin of our domestic animals and plants, there can be no doubt as to the matter of fact that breeders have always proceeded on one principle,—*select the best individuals in each generation and pair them.* Now we have found that the qualities of organic beings (forming in a certain sense the material on which the breeder has to work) can be generalized under two principles—heredity and variability. And in the same way the art of breeding is itself capable of a kind of generalization under the principle of selection. There are thus three great principles or laws—heredity, variability, and selection,—the last relating to the art of man, the other two to those qualities of organic beings which render the art practicable.

Heredity.—The simplest form of heredity is found amongst those organisms which reproduce their kind by division into two parts similar to each other. This process is illustrated by the fission of a Moneron. The next advance in complexity of reproduction occurs when the two portions into which the organism divides are dissimilar to one another; here the process by which both portions ultimately assume the form of the parent is not one of simple nutrition, *i.e.*, of formation of tissue like that already formed. The process by which man propagates some of his cultivated plants is one of artificial reproduction by fission. For instance, a cutting or part of a shoot, or even a leaf (as with Begonia), if placed in suitable soil, will reproduce the original plant in all its minute details. We are here face to face with the mystery of reproduction; for we have the ever wonderful fact that in a few cells lies dormant the vital impetus which enables them to produce from inorganic pabulum a most complicated structure, which in its totality is utterly unlike themselves. And this example shows us, moreover, how essentially the same are sexual and asexual reproduction; for there is no intrinsic difference between reproduction from a small part artificially separated from a simple foliar organ (a leaf) and the same sequence of growth originating in a small portion naturally segregated from a transformed foliar organ (the ovary). The conditions of growth are not the same in the two cases, and there all essential difference ends; for the broad distinction which the congress of two individuals in one case appears to make is swept away by the facts of Parthenogenesis. In the lowest of living things we have seen that growth and reproduction are almost identical aspects of life. And this connection is not less close among higher organisms; as Mr Herbert Spencer observes,—"When in place of its lost claw a lobster puts forth from the same spot a cellular mass, which, while increasing in bulk, assumes the form and structure of the original claw, we can have no hesitation in ascribing this result to a play of forces like that which moulds the materials contained in a piece of Begonia leaf into the shape of a young Begonia. In the one case as in the other the vitalized molecules composing the tissues show their proclivity towards a particular arrangement; and whether such proclivity is exhibited in reproducing the entire form or in completing it when rendered imperfect matters not."[1] The main fact of inheritance is so obvious that it is apt to be forgotten. Mr Darwin remarks,—"It is hardly possible, within a moderate compass, to impress on those who have not attended to the subject the full conviction of the force of inheritance, which is slowly acquired by rearing animals, by studying the various treatises which have been published on the various domestic animals, and by conversing with breeders."[2] Certain peculiarities have appeared only once or twice in the history of the world, but have reappeared in children or grandchildren of the individuals so characterized. Thus Lambert "the porcupine man," whose skin was covered with warty projections, which were periodically moulted, had all his six children and two grandsons similarly affected. The most striking cases of inheritance have, as in this instance, been observed in man; but the very existence of the numerous breeds of domestic animals is clear evidence of the possibility of the transmission of every kind of peculiarity. For instance, it is believed that the varieties of the domestic pigeon amount to at least 150, and these races differ from each other in many ways, and all breed true to their kind. Some very curious peculiarities have been perpetuated. A race of cattle called "Dutch buttocked" was formed in Yorkshire by selecting in each generation the animals with the largest hinder-quarters. When the breed began to be established it was found that the large size of the calves' hind-quarters increased the dangers of parturition to a considerable extent. This case is interesting as showing that hurtful peculiarities may be inherited just as readily as those which are beneficial, and as bearing witness to the improbability of the view that there is an innate tendency to vary in the right direction. The terrible strength of inheritance exhibited by disease is a fact which is only too well established in the case of man; and in the maladies of domestic animals the same law holds good. It appears that nearly all the diseases to which the horse is subject are hereditary,—for instance, contracted feet, curbs, splints, spavin, founder, and weakness of the fore legs, roaring or broken and thick wind, melanosis, specific ophthalmia, and blindness, and even such habits as crib-biting and jibbing, are all plainly hereditary. The fact that any, even the most complex combinations of qualities are capable of hereditary transmission, is, perhaps, more forcibly brought home by considering the monetary aspect of the art of breeding, than by the fullest collection of special instances. As Mr Herbert Spencer remarks:—"Excluding those inductions

[1] *Principles of Biology*, London, 1866, p. 181.
[2] *Op. cit.*, vol. ii. p. 4.

that have been so fully verified as to rank with exact science, there are no inductions so trustworthy as those which have undergone the mercantile test. When we have thousands of men whose profit or loss depends on the truth of the inferences they draw from simple and perpetually repeated observations; and when we find that the inferences arrived at and handed down from generation to generation of these deeply interested observers has become an unshakeable conviction, we may accept it without hesitation. In breeders of animals we have such a class, led by such experiences and entertaining such a conviction—the conviction that minor peculiarities are inherited as well as major peculiarities. Hence the immense prices paid for successful racers, bulls of superior form, sheep that have certain desired peculiarities."[1] Not only are slight and gradual changes inherited, but in some cases sudden and well-marked variations are strongly transmitted. The case of the Niata cattle is now well known; a similar case is recorded of a rabbit born with only one ear, from which a breed was formed which steadily produced one-eared rabbits. These remarkable cases of sudden and large variation being inherited are closely allied to the still more curious phenomenon of the inheritance of mutilations. The most striking cases on record are those of Brown-Séquard.[2] In his experiments on the inheritance of artificially produced epilepsy he found that guinea pigs, after having undergone section of the sciatic nerve, often nibbled off portions of their hind legs in consequence of the anæsthesia of those parts. Now the offspring of these self-mutilated animals were in thirteen cases born without toes. To appreciate the true value of this case it must be noted that Dr Brown-Séquard has for thirty years kept guinea pigs, and has had many thousands under observation, and *not a single case* of congenitally toeless animals has occurred excepting among the offspring of mutilated parents. In spite of the universal tendency towards the transmission of the form and qualities of the parents to the offspring, there occur capricious and inexplicable lapses in inheritance. It is not possible logically to distinguish a want of inheritance from a case of variation; but when the difference between the offspring and the parent consists merely in the absence in the former of a quality possessed by the parent, it may be more conveniently classed as a want of inheritance than as an instance of variation. Although a weeping or pendulous habit in trees is in some cases strongly inherited, in other instances the want of inheritance is equally well marked. Mr Rivers sowed above 20,000 seeds of the weeping ash, and not a single seedling was in the least degree pendulous. M. Borchmeyer has also observed the same fact in Germany. In all cases it must be remembered that the form and qualities which the offspring of an animal or plant will assume when fully developed are not solely dependent on the nature of the hereditary impetus with which it starts; the initial tendency is as it were calculated so as to impart under certain conditions a certain form to the organism. If the conditions change, the initial tendency will not lead to the proper result; and it is to be noted that the apparent amount of alteration in the conditions is no measure of the amount of effect produced on the organism. For instance, none of the English breeds of sheep can be kept pure in France, the lambs of even the first generation lose vigour as the heat of the summer comes on, and the breed becomes absolutely degenerate. It is extremely curious that the force of inheritance which seems all powerful in England should give way so utterly under such a slight change of circumstances.

The method by which a breed was formed, combining the valuable qualities of the English sheep with a constitution fitted for the French conditions of life, is most instructive, and is a triumph of thoughtful and scientific breeding. The successful attainment of this end is due to M. Malingié-Nouel. He found that the offspring of a cross between a pure English ram and a French ewe inherit the desirable form of the sire, but, unfortunately, also his undesirable constitution. He accordingly paired a ewe taken from a border district, and therefore intermediate between two breeds, with a similar intermediate ram. He thus produced a sheep "combining the four races—Berry, Sologne, Merino, and Touraine . . . without decided character, without fixity, . . . but possessing the merit of being used to our climate and management."[3] It was now found that the lambs born of this mongrel ewe by purely-bred New Kent rams combined the English form with the French constitution, and transmitted this desirable combination to their offspring, and in this way the "Charmoise" breed was produced.

In this instance it seems as if the tendencies supplied by the ewe formed so discordant a combination that no strong tendency resulted for any of the French forms to appear, so that the form of the English ram was strongly impressed on the offspring. On the other hand, the *constitutional* tendencies coming from the mother's side were not discordant, but united in impressing the French constitution on the offspring. This case is instructive as establishing the possibility of an important kind of acclimatization, and as bearing on a somewhat exceptional phenomenon of heredity, namely, that when *both* parents exhibit a given character strongly, the offspring do not inherit it so surely as when one parent only is especially well characterized. Thus a successful breeder of laced Sebright bantams says,—"I am confident that those that are best laced frequently produce offspring very far from perfect in their markings, whilst those exhibited by myself which have so often proved successful were bred from the union of heavily laced birds with those that were scarcely sufficiently laced."[4] The class of cases just noticed is, moreover, of great interest as bearing on a form of inheritance which has been named "prepotency of transmission." When the offspring, instead of being intermediate between the parents, strongly resemble one of them, the latter is said to be prepotent in transmitting its likeness. The famous bull Favourite is believed to have had a prepotent influence on the short-horn race. It has also been observed with English race horses that certain mares have generally transmitted their own character, while other mares of equally pure blood have allowed the character of the sire to prevail.

In other cases a remarkable weakness of transmission of character is found to exist. A striking instance is given by Mr Brent.[5] It must be premised that the breed of pigeons known as "trumpeters" is characterized by a tuft of feathers over the beak, by a crest on the head, and by a most peculiar coo. Mr Brent crossed a trumpeter with another breed, and then recrossed the mongrels with trumpeters. But it was only at the fourth generation, when the birds had $\frac{15}{16}$ trumpeter blood in their veins, that the characteristic tuft appeared, and even then the peculiar trumpeting coo was absent.

It is frequently asserted that the male is prepotent over the female in transmitting certain characters. It has been shown,[6] however, that such rules do not hold good except

to a very limited extent, and in certain groups only. It frequently happens that a character existing in one of the parents is transmitted more powerfully to the offspring of the sex to which that parent belongs than to the opposite sex. The large and important subject of secondary sexual characters hinges entirely on this phenomenon. The resemblance between prepotency and sexual limitation becomes clear when we remember that where the offspring are of one sex it may be impossible to distinguish between these forms of heredity. The most interesting point connected with secondary sexual peculiarities in relation to the subject of breeds is, that they are sometimes found in domesticated animals whose nearest wild congeners show no such limitation of character. Thus in the sheep, the males of certain races differ greatly from the females in the shape of their horns, in the development of fat in the tail (in certain fat-tailed breeds), and in the outline of the forehead. These differences are interesting because, so far as we know, similar secondary sexual differences are not found in the nearest allied wild species of sheep. On the other hand, secondary peculiarities which originally distinguished the sexes are in some cases diminished or removed by domestication. Thus our improved breeds of pigs have to a large extent lost the formidable tusks of the wild boar. The existence of secondary sexual characters gives a striking illustration of another important law of inheritance. This law asserts that the age at which any character first shows itself in the offspring is the same as that at which it appeared in the parent. Now, secondary sexual characters—those, for instance, presented by the male sex—have apparently been developed by sexual selection, and this force can only be brought to bear on variations occurring in adult animals. If, then, the male offspring do not develop the selected peculiarities until they arrive at puberty, the age at which it appeared in their male parent, it is clear that they cannot differ from the female until the age of puberty arrives. And this is well known to be the case, for at an early age the sexes are usually undistinguishable by any secondary characters. (See *Descent of Man*, vol. i. chap. viii.)

The interesting form of inheritance exemplified by the transmission through the female line of diseases necessarily confined to the male sex has been already alluded to. This latency of male characters is clearly illustrated by what frequently occurs to old hens. It is well known that a large number of female birds, when old or diseased, partly assume the secondary male characters of their species. Waterton (*Essays on Nat. Hist.*) gives a curious instance of a hen which had ceased laying, and had assumed the plumage, voice, spurs, and warlike disposition of the cock. The opposite case of the assumption by the male of female characters is illustrated by the fact that capons sometimes acquire the sitting instinct of the hen.

The possibility of characters existing in a latent condition is of the utmost moment to the breeder, since upon it depends the possibility of reversion or atavism. Reversion is a matter of extreme importance to the breeder, for it is one of the serious hindrances to the progress of his art. Since the time of the famous Bakewell during last century, Leicester sheep have been bred with the most scrupulous care, yet grey-faced, black-spotted, or wholly black lambs occasionally appear. In this case the most careful selection has been necessary to battle against the tendency of the original colouring of the sheep to reappear. And in all cases of selection it is this tendency that has to be struggled against by the breeder. On this principle the gardener looks over his beds and weeds out the "rogues." Even from seeds gathered from the finest cultivated varieties of the heart's-ease (*Viola tricolor*), plants perfectly wild both in flowers and foliage are frequently produced. The proximate cause of any particular case of reversion is utterly obscure; but some of the general causes may be set down. It is frequently asserted that domestic animals or cultivated plants, when allowed to run wild, always revert to the original parent form of the species. This assertion appears to rest on insufficient evidence, and to be an exaggerated statement of what is known on the subject. Nevertheless some weight must be allowed to it. Pigs have run wild in various parts of the world, and have everywhere acquired the general characters of the wild pig, and the young have re-acquired the longitudinal stripes. This last character is interesting, since it is not in any way a direct result of the changed conditions of life, as the thicker bristles and increased size of the tusks might be supposed to be. Another well-established cause of reversion is *crossing*. The case is exceedingly striking when the offspring of a cross do not resemble any near progenitor, but throw back to very remote ancestors. In illustration may be mentioned the experiments on pigeons detailed in the *Variation of Animals and Plants under Domestication* (vol. i. p. 200). There can be but little doubt that all our domestic races of pigeons have descended from *Columba livia*, the wild rock pigeon; the common dovecot pigeons exhibit the coloration of the parent form, and the most purely-bred fancy breeds, when of a blue colour, often show these characteristic marks. One of the above-mentioned experiments consisted in pairing a "mongrel female barb fantail with a mongrel male barb spot, neither of which mongrels had the least blue about them." It appears that blue barbs are exceedingly rare, that the spot has been known as a pure breed for nearly 200 years, and that a white fantail throwing any other colour is almost an unknown occurrence; nevertheless the offspring from the above two mongrels were of exactly the same blue tint over the whole back and wings as that of the wild rock pigeon from the Shetland Islands. Moreover, every characteristic mark of the wild pigeon was repeated in their mongrel offspring. This experiment demonstrates in the most striking way the tendency of a cross to produce reversion. The same result was also obtained by pairing black Spanish cocks with hens of various white breeds. In this case the offspring reverted to the red colouring of *Gallus bankiva*, which may be safely ranked as the parent form of our domestic fowls. In these instances the offspring revert to a character originally possessed by the ancestors of both parents, and here the cross is in no way essential to the reversion; it merely acts as a disturbing cause (although, probably, no other equally strong disturbing power could be named). In these cases reversion to a character of any degree of antiquity may occur. In the other class of cases where the character to which the offspring revert is one given by a single cross with a distinct variety, the tendency to reversion becomes weaker in each generation removed from the cross, and may ultimately be obliterated. The length of time requisite to effect obliteration has formed a subject of discussion. The question can hardly be answered, but the fact that it has been asked shows at least that obliteration may in some cases be effected in a practically finite period. In other cases even characters gained in this way by a single cross seem incapable of extermination. Fowls have been known to exhibit a Malay character, due to a cross with that breed forty years previously.

Variability.—When in any case we find the offspring differing from the parent, we set it down at first sight as an instance of variability. But on the discovery being made that the peculiarities characterizing the offspring are derived from a remote ancestor, it can no longer be so considered, and must be attributed to reversion. Many cases of apparent variation are due to this cause. Thus Gärtner declares, and his experience is of the highest value

on such a point, that when he crossed distinct species of native plants that had not been cultivated, he never once saw in the offspring any new character; but that, from the odd manner in which the characters derived from the parents were combined, they sometimes appeared as if new. It appears, therefore, that the point at which the line of distinction is drawn between reversion and variation depends in many cases on the state of our knowledge of the subject. In some other points, also, the relations between inheritance and variation are extremely intricate and difficult to unravel. These two principles are often spoken of as opposed to one another. The following case shows that any definition of variability implying that it is necessarily equivalent to a breach in the law of heredity is incorrect. Some kinds of sheep and cattle dogs are congenitally almost destitute of a tail; and this Stonehenge attributes to the fact that under the old excise laws only those dogs whose tails had been removed were exempt from taxation; so that this mutilation was universally practised until the deficiency became hereditary. The production of a tailless breed of dogs must certainly be considered a case of variation, yet in this case it is not a *breach* of the law of heredity, but a remarkable instance of obedience to that law, that is to say, of the transmission of the effects of mutilation. In other cases external causes produce some constitutional or otherwise imperceptible changes in the parent, and these in being transmitted to the offspring become correlated with some external or *perceptible* alteration, and in this way new characters may appear. This is undoubtedly a true case of variation; nevertheless, strictly speaking it is due to the inherited effects of a cause acting on the parent. And it seems illogical to separate it in a radical manner from cases such as that of the tailless breeds of dogs. Considering, therefore, the great difficulty in which the subject is enveloped, it will be well to abandon theoretical considerations, and merely to state that characters at least practically new do undoubtedly appear in the offspring. In every group of organisms a degree of variability, sufficient to give material for the breeder to work on, probably exists. The Laplander knows and gives a name to each of his reindeer, though, as Linnæus remarks, "to distinguish one from another among such multitudes was beyond my comprehension, for they were like ants on an ant-hill." A still more striking case is that of the old Dutch florist Voorhelm, who kept above 1200 varieties of the hyacinth, and was hardly ever deceived in knowing each kind by the bulb alone. These cases are important as showing that, even in natural objects which appear identical to the unpractised eye, perceptible differences do exist. Man can effect nothing until some of his stock begin to vary in the desired direction. But horticulturists have found by experience that when any particular character is desired, the first step is to get the plant to vary in any manner, and to go on selecting the most variable individuals even though they vary in the wrong direction, for the fixed character of the species being once broken through the desired variation will sooner or later appear. The great number of races of many domestic animals and plants—for instance, of pigeons, sheep, wheat, &c.—demonstrates clearly their variability in many diverse characters. In other domestic animals, however, very few distinct races exist; yet we must not conclude that these animals have not varied. There are several causes besides that of an inherent want of plasticity which may have been at work. It will here suffice to allude to a few of them.

1. If any particular group has not been especially subjected to selection, the absence of distinct races in such a group is no proof of want of variability. This applies to asses (in England only).

2. If the breeder has not a large number of individuals to select from, the chance of the required variations occurring is very small. Hence animals kept in small lots do not form races (*e.g.*, sheep on small holdings).

3. If intercrossing cannot be prevented, it is obvious that any variety which may appear will have no chance of being perpetuated, but will be diluted down to the normal type. This applies to cats, which, from their wandering and nocturnal habits, cannot be paired.

It may appear a truism to say that every variation must have a distinct cause, but it is a truism very often overlooked. The case of twins, each born with a peculiar crook in the little finger, is instructive, for here the conclusion is irresistible that the same definite, though unknown, cause produced the mal-formation in the two children. This case may also serve to illustrate the extreme obscurity in which the causes of any given variation are hidden, and the great difficulty of investigating them. Some general causes which induce variability may, however, be set down.

There appears to be no doubt that organisms subjected to the unnatural and changeable conditions implied by domestication are more variable than those living in a state of nature. Thus monstrosities are comparatively frequent among domestic animals and plants.[1] Domestication causes a number of changes in the condition of life; it is therefore of interest to determine which of these are the most important. Contrary to what might have been expected, change of climate is not an important cause of variation. This is repeatedly shown by A. de Candolle in his *Géographie Botanique;* and a change to a more genial climate is certainly not necessary, for the dwarf kidney bean, which is often injured by our spring frosts, and the peach, which requires the protection of a wall, have varied much in England. (See ACCLIMATISATION.)

In some moths the colour of the perfect insect is affected by a change in the food of the caterpillar, but there seems to be no evidence that this cause has been active in inducing variability in our domestic races. On the other hand, *excess* of food is probably an important cause of variability. This view was held by Andrew Knight, and the same idea is expressed in the following remark of a "great raiser of seeds:"—"It is a rule invariably with us, when we desire to keep a true stock of any one kind of seed, to grow it on poor land without dung; but when we grow for quantity we act contrary, and sometimes have dearly to repeht of it."[2] Nevertheless it appears that many of the best varieties of fruit have not been produced under cultivation. Thus it is asserted that some of the finest French pears were originally found growing wild, and this was the case with an English variety of apple. The most interesting fact connected with changes in the conditions of life is that the results of such changes are capable of accumulation. It is this peculiarity that accounts for the fact that when new flowers are first introduced into our gardens they do not vary. Thus the Swan River daisy did not break from its original colour until it had been subjected to seven years of high culture. Many facts might be given showing by what slight changes of habitat the health and general development of animals and plants may be affected;[3] but with these cases we are not especially concerned. (See ACCLIMATISATION.) The causes, however, which induce an unstable condition of general variability are of great importance to the breeder. Of the causes not already touched on the most important is intercrossing. In considering variations under this aspect no attempt will be made to distinguish from true cases of variation the cases in which new characters are simulated by combinations of old ones. In the first place, it is probable that organisms propagated by *sexual* reproduction

[1] J. Geoffroy St Hilaire and Moquin Tandon.

[2] Quoted in *Var. under Domes.*, ii. p. 257.

[3] See *Var. under Domes.*, vol. ii. ch. xxiii., on "The Definite Action of the Conditions of Life."

are usually the most liable to variation. For here the offspring has a double chance of being influenced by circumstances affecting the parents; and by the concentration of a double set of tendencies into one individual, a better chance is given for the origin of variations produced by combinations of ancestral characters. In the same way, to a certain extent, a cross with a distinct variety produces a disturbance or loss of equilibrium in the reproductive system from which a tendency to the production of variations results. Thus Gärtner asserts that seedlings from *Dianthus barbatus*, when crossed by the hybrid *D. chinensi-barbatus*, were more variable than those raised from this latter hybrid fertilized by the pure *D. barbatus*. Max Wichura insists strongly on an analogous result in the case of willows; and Kölreuter says that to obtain an endless number of varieties from hybrids they should be crossed and recrossed.

Some peculiarities in our domestic races are to be attributed to the inherited effects of habit and of disuse. Splints and ring-bones on the legs of horses appear to be certainly hereditary; and veterinary surgeons agree in pronouncing these growths to be the result of travelling on hard roads, and of the horses being shod. The effects of disuse are clearly shown in the skeletal characters of our domestic races. These effects are well marked in tame birds, which are necessarily prevented from exercising their wings in flight. Thus in the domestic duck the crest of the sternum is less prominent, the furculum, coracoids, and scapulæ are all reduced in weight relatively to that of the whole body; the bones of the wing are shorter and lighter, and the bones of the leg longer and heavier in comparison with the same bones in the wild duck. Closely connected with this class of facts is the subject of rudimentary organs. In organisms living in a state of nature the constant pressure of the struggle for existence tends to keep useless structures in a rudimentary condition. But domestication, in removing this pressure, does away at the same time with the principle of economy of growth; and accordingly, we find that organs rudimentary in a state of nature become developed under domestication. Thus cultivation has made true branches out of the thorns or rudimentary branches of the wild pear. Again, the rudimentary fifth toe on the dog's hind foot becomes in some cases considerably developed, and forms the "dew-claw" of a few large breeds.

Correlation has probably played an important part in modifying domestic races; for in selecting a given character man has frequently perpetuated many other peculiarities correlated with the first.

Finally may be mentioned the curious phenomena of "analogous variation." This term is applied to those cases in which varieties of one species resemble distinct but allied species. Where this occurs it is probably due to the two forms having originated in a common progenitor, so that modifying causes evolve similar varieties in the two cases because of the similarity of the material which these forces have to act on. Analogous variation is therefore, properly speaking, a branch of the subject of reversion, and once more points out the close connection existing between the latter phenomenon and variability.

In purely bred fowls of many races, birds may occasionally be found closely resembling the *Gallus bankiva*. Here the case is one of simple reversion, and has already been alluded to. The production of spangled sub-breeds of Hamburgh, Polish, Malay, and Bantam fowls is not an obvious case of reversion to a known ancestor. It may be due, however, to descent from the parent form of the Gallinaceæ, considering the frequency of spangled markings throughout the order.

Selection.—Selection may be defined as the process by which the procreators of each fresh generation are chosen out of the preceding one. But with reference to the formation of our improved breeds something more than this is meant by the term. The modern development of the art, which has been distinguished by Mr Darwin as *methodical selection*, always implies that the breeder has before his mind an ideal form,—a model on which he attempts to mould his strain. To be successful in this respect a man must not only possess in the highest degree the powers of discrimination, enabling him to determine which individuals are tending in the right direction, that is, which most nearly approach his ideal, but he must be able to decide, in the most judicious manner, as to which of his selected individuals ought to be paired together. The subject, therefore, falls naturally into two divisions—(1) the discrimination of individual differences, (2) the arrangement of the pairing.

1. *Discrimination of Individual Differences.*—The extremely fine powers of perception and the great patience required by the breeder might be illustrated by numerous instances. Sir John Sebright is said to have sometimes spent several days in weighing the rival merits of five or six birds. In Germany the merino sheep farmers do not even trust their own judgment, but employ professional "sheep classifiers" to select the best of the flock for breeding purposes. Not merely outward form, but internal and constitutional peculiarities have been carefully attended to by breeders. Thus, Bakewell (the first true methodical breeder of whose proceedings we have any knowledge) bred almost entirely for the early maturity and fattening qualities of his strain; and again, in the improved short-horn breeds, the masses of internal fat or tallow have been increased to an almost incredible extent.[1] Professor Low states,[2] as an instructive instance of the limits that should be put to the exaggeration of any one point, that even the great Bakewell appears to have made this mistake in causing a useless accumulation of fat where it was not needed. It seems that the fat mingled less with the lean than even in the old breeds, and that it spread in layers under the skin, forming cushions of fat. He quotes a writer who observes that, having with great difficulty formed a race of cattle that would "make fat," Bakewell left his successors under the necessity of producing a breed that would "make lean." The same kind of error was at one time committed with the improved short-horns, whose progenitors were pre-eminently good milkers; here the breeders, by attending exclusively to other qualities, have in some cases injured the milking powers of the race. Youatt is convinced that this loss is not necessarily correlated with rapid feeding qualities.[3] He asserts that by careful selection a strain may be obtained (and this has, in fact, been effected) in which the cows are first-class milkers, and when dried fatten quickly and well.

In spite of these warnings against exclusiveness and exaggeration, it should be remembered that the difficulties of selection are greatly increased by attention to several points at once. An illustration of this may be taken from the less important art of fancy breeding. An eminent fancier in speaking of the almond tumbler pigeon (a breed having five points, viz., plumage, carriage, head, beak, and eye), remarks that "there are some young fanciers who are over covetous, who go for all the above five properties at once; they have their reward by getting nothing." Mr Darwin observes, "We may smile at the solemnity of this precept, but he who laughs will win no prizes."

It should be remarked, however, that "fancying" is not governed by rules identical with those which regulate breeding for economic purposes. The fancier often has to strive after extreme abnormal development, amounting to monstrosity; it has often been remarked that he will not tolerate anything short of this extreme divergence. On the other hand the economic breeder is prevented by solid monetary considerations from being misled, to any great extent, by fashion. Hence, instead of the wide differences observable in "fancied" animals, we find a remarkable uniformity in certain characters among many of those bred for use. Thus all the improved races of the pig closely resemble each other in their shortened legs and muzzles, their large hairless bodies and small tusks. Well-bred cattle of several distinct races exhibit a similar convergence of character.

2. *Arrangement of the Pairing* (including crossing).—We have already alluded to the remarkable case in which it seems an advantage to the offspring that one parent *only* should possess the desired quality in an especial degree. This may be considered an extreme case, yet it bears some relation to the principles on which breeders usually regulate the arrangement of the pairings. Generally speaking, individuals having certain points peculiarly well developed are matched with those excelling in other directions. It is probable that a physiological law which would formulate the exceptional cases above mentioned would also favour the more common practice

[1] Youatt, *Cattle*, 1834, p. 227, *et seq.*
[2] *Domesticated Animals*, 1845, p. 378.
[3] *Op. cit.*, p. 239.

now under consideration. For it would allow the transmission of qualities from either parent, undisturbed by the influence of the other, to the offspring. In this part of his work the breeder once more finds occasion for the utmost skill and judgment; but so difficult to formulate are the fruits of his experience that he often seems guided in his choice by instinct rather than by reason. Every new breed must originate in a few individuals possessing some special peculiarities. Therefore, nearly-related individuals must at first be matched; in other words, close "in-and-in" breeding must be practised, or the race cannot be "fixed." In consequence of the uniformity obtained by pure breeding, characters otherwise unimportant become valuable as marks of purity of race. Thus the dark red colour of the Devon cattle becomes a criterion of "blood."

The advantages of in-and-in breeding have been insisted upon by the improvers of our domestic breeds, and some of them have declared that no ill results follow from the practice. But in spite of this assertion it is generally admitted that degeneration either in constitution or in other ways does ultimately ensue; so that at any cost the breeder is absolutely compelled to admit blood from another family or strain of the same race. In speaking of this necessity in the case of sheep, Youatt says that the breeder will choose "a ram from a soil and kind of food not dissimilar to his own, . . . with points as much resembling his own sheep as may be—quite as good as those in his own flock—superior if possible in some points, inferior in none." But in opposition to Youatt it may be argued, from the practice followed by some great poultry breeders, that animals having the same physical characters, but which have been kept under different *conditions*, ought to be selected for crossing. By this means tone and vigour are infused into the stock without materially altering its character. In other cases a different plan has been followed. For instance, Colling (for what purpose is not clear, on account of the secrecy in which he carried out his art) crossed his short-horns with a distinct breed—the Galloway. He thus produced a sub-strain or family, called in reproach the "Alloy," but possessed of great merits, which, by recrossing with short-horns, became quite equal to the pure breed,[1] and produced animals which sold for enormous prices. This method of making one "violent" cross, and trusting to subsequent recrossing with the pure parent form (together with long continued selection), has sometimes been followed where some especial quality is required. Lord Orford's well-known attempt to infuse pluck into his greyhounds by means of a cross with a bull-dog is a case in point. Stonehenge records a carefully-observed experiment of the same kind, which shows that the objectionable form of the bull-dog can be thoroughly eradicated even in four generations. In other cases a cross with a distinct variety is effected with the object of forming an intermediate race which shall transmit its characters.

Crossing.—An injudicious exaggeration of certain qualities, as in some cases before alluded to, has taken place in breeding long-woolled sheep. Here the fleece has been almost exclusively attended to, and the quality of the carcase allowed to deteriorate. No doubt, an improved breed remedying this evil might have been formed by selection, but this process would have been slow and extremely difficult; and, fortunately, there existed the readier method of forming a cross-breed race combining the desirable characteristics of both varieties. Messrs Druce and Pusey[2] have pointed out the great increase of profit yielded by a cross between the long and short-woolled sheep The following table gives in the first column the number of Cotswolds, Southdowns, and sheep of a "cross breed" intermediate between them, which a given area will support; the second gives the total value of fleece and carcase in each case for the number of animals given in the first column:—

Cotswold	100	£496
Southdown	120	488
Cross-breed	115	597

Crossing has, in fact, entered largely into the formation of nearly all our improved sheep.[3]

In some cases the offspring of a first cross between distinct species possess valuable qualities, but owing to their sterility an intermediate *race* cannot be formed. If, however, the combination is valuable the cross may be repeated at will. The breeding of mules is a familiar example of this method. In the same way cross-bred cattle, which though not sterile are yet incapable of transmitting their valuable qualities to their offspring, are bred for the butcher by a repetition of the first cross.

Some of the more important points in connection with methodical selection and the modern art of breeding have now been briefly indicated. The results obtained have been truly astonishing. Lord Somerville graphically remarked that the modern sheep-breeder appeared to have "drawn a perfect form and then to have given it life." These extraordinary improvements have been effected almost within the last century; and it may be objected that because selection as now practised is of modern date, the differences which characterize many races of great antiquity cannot have been produced by man. This objection, however, is not valid, for it can be shown that an unnoticed and therefore unrecorded cause of modification has long been in existence. This important agent has been named "unconscious selection;" it is illustrated by the following case. In speaking of two flocks of the New Leicester sheep possessed respectively by Messrs Buckley and Burgess, Youatt remarks that "both of their flocks have been purely bred from the original stock of Mr Bakewell for upwards of fifty years. There is not a suspicion existing in the mind of any one at all acquainted with the subject, that the owner of either of them has deviated in any one instance from the pure blood of Mr Bakewell's flock; yet the difference between the sheep possessed by these two gentlemen is so great that they have the appearance of being quite different varieties."[4]

Now we may feel sure that neither of these breeders intended to alter the character of his flock, he merely strove to produce the best possible New Leicester sheep and selected those which approached his ideal most closely. Yet owing to slightly different standards of excellence having been unconsciously aimed at in the two cases, the important results pointed out by Youatt arose. It is an exceeding remarkable fact, that changes so small as not to be perceived by the trained eye of the modern breeder may by accumulation produce obvious results in the short space of fifty years. And if such changes may occur unnoticed under the supervision of men keenly alive to the possibilities of change, a far greater field for this kind of modification must have been offered before any such knowledge was general. An unperceived divergence of character will arise whenever men, actuated by some vague belief in heredity, begin to select the best individuals, roughly speaking, for reproductive purposes. Each man will unconsciously take a standard of excellence slightly different from his neighbours, and thus his strain will imperceptibly begin to differ from theirs. Now there can be no doubt that an amount of selection sufficient for this purpose must have been practised from a very remote period. Youatt, after an examination of the passages in the Old Testament bearing on the subject, asserts that some of the best principles of breeding were then understood. The antiquity of breeding is also proved by certain passages in ancient Chinese encyclopædias.

The ancestors of nations at present civilized must have passed through stages in which they resembled the savages of the present day; therefore it may fairly be assumed that customs which are found among lowly developed savages are of great antiquity. Now few races are more barbarous than the Australians, yet even they take pains in the breeding of their dogs, matching the finest together and providing good food for the mother in order that the young may be well nurtured. From a large body of similar evidence there can be no doubt that a degree of selection sufficient for the development of unperceived divergence has been

[4] *The Sheep*, p. 315.

practised from exceedingly ancient times. The results produced by prolonged selection of this kind may be estimated in various ways. For instance, although it is certain that the pointer originally came from Spain, no such breed exists there at the present day. So far as is known no efforts have ever been made to modify the pointer; but every one has wished to possess as good dogs as possible, and by an unconscious consensus of opinion, the desire for improvement has resulted in a slow progressive change in a certain direction. But the amount of divergence produced by long-continued selection may be illustrated more forcibly by general considerations than by special instances. The fact that the progenitors of many cultivated plants and domestic animals cannot with certainty be determined points out the great divergence from the wild parent form that has been effected under domestication. The genus *Auchenia* may serve as an illustration. There are four forms in this genus—the guanaco and vicuña, found wild, and undoubtedly distinct species, and the llama and alpaca, known only in a domesticated condition. Most professed naturalists have looked on all four forms as specifically distinct, and have made the assumption that the wild llama and alpaca have become extinct. But Mr Ledger appears to have proved conclusively[1] that the llama is the domesticated descendant of the guanaco, and the alpaca that of the vicuña,—so that a large amount of divergence must have been effected in this case. And as we know that careful selection was anciently applied to these animals, there is nothing inconceivable in such a transformation having been effected. The power of long-continued selection is well shown by the fact that, in domestic animals and plants, the parts or qualities valued by man have been most modified; thus the sheep has been prized during many ages for its fleece, the horse for its strength and fleetness, and, accordingly, we do not find breeds of sheep differing from each other in strength and fleetness, or breeds of horses distinguished by the properties of their hair, but on the contrary both animals have produced races characterized by differences in the qualities for which they are valued. The same law is even more clearly demonstrated by plants under cultivation. In the radish, which has been esteemed exclusively for its root, it is the latter that differs in the several varieties, while the flowers, seed, and foliage are almost identical in all. Again, the varieties of the gooseberry differ much in their fruit, but hardly perceptibly in their flowers and organs of reproduction. In some cases structures neglected by man have varied by correlation; but allowing for this exception, they may be said to have escaped the effects of selection, and accordingly to have remained stationary, while the selected qualities have gradually improved.

In attempting to frame an answer to the question—How much has man actually effected? it will be well first to estimate the amount of modification which may be claimed as his work, and then to measure the efficiency of the agents by which these results are believed to have been effected.

(1.) Organic beings resemble each other in descending degrees, so that they can be classed in groups under groups,—classes, orders, genera, &c. The doctrine of evolution gives life to this arrangement and makes it truly a "natural" classification,—the idea of different degrees of community of descent being added to that of arbitrary classification by community of characteristics. Thus it happens that the number and distinctness of the genera contained in a natural family become to a certain extent a gauge of the amount of divergence which the modifying causes of nature have produced, since the time when all the genera were united in the parent form of their family. And by a similar method we may estimate the amount of divergence that man has effected. For instance, there can be no doubt that all the varieties of the domestic pigeon are the descendants of the rock pigeon, and have sprung up under the care of man during the long period of time that has elapsed since their wild ancestor was first domesticated. These varieties amount to more than 150 in number; and there can be no question that, supposing them to be found wild, they would be grouped under at least five distinct genera,—so great are differences existing among them. This instance gives some idea of the marvellous amount of modification that may arise under domestication.

(2.) Are the powers which man possesses of producing modification sufficient for the work assigned to them? It will be well to set down the assumptions which may fairly be made in connection with this point.

First, the labours of the great breeders teach us what enormous changes can be effected in the short space of one man's life; and we know that the essential principles involved in the process were anciently known and followed.

Secondly, we may feel certain that great divergence of character is unconsciously produced during long continued selection of any kind; and we know that some kind of selection must have existed from remote periods. Logically considered, therefore, the possibility of almost any degree of divergence having been effected turns in great measure on the question of the antiquity of selection.

It is therefore important to note that an indirect kind of selection must almost necessarily be coeval with domestication. For this can be shown to be the case with tame animals possessed by the rudest savage, who does not regulate their increase in accordance with even the vaguest belief in heredity. In each litter of puppies, for instance, some would necessarily be destroyed, for their master would be unable to preserve all the young ones which were produced. He would certainly not save those which were small, feeble, or deficient in any valuable quality. The finest in each generation would then be preserved, merely because it was believed that they, individually, would be useful, and not with any idea of "breeding." Nevertheless, it would indirectly follow that the superior individuals in each generation would, as a rule, form the progenitors of the next one; that is, a kind of indirect selection would arise. If then we can be sure that domestication, in some form, has existed from remote times, we may feel tolerably certain that the above-described rude form of selection must be of nearly equal antiquity. Apart from the direct proofs on this head which we possess in the remains of the prehistoric period, there is a high antecedent probability in favour of the extreme antiquity of domestication; for it is certain that tame animals are of great use to savages, and the wild progenitors of many of our domestic creatures are rendered tame with ease. This is the case with wild dogs, pigs, cattle, ducks, &c. In the case of vegetables, it appears that, in times of scarcity, savages devour almost any berries or leaves which they can obtain, often suffering terribly in consequence; and in this way plants at all superior in nutritious qualities would assuredly be discovered. We may, therefore, conclude—(1), that the domestication of animals and the culture of plants date from exceedingly remote antiquity; (2), that a certain amount of selection must have been nearly coeval with domestication; (3), that some degree of divergence of character must almost necessarily have accompanied selection; and (4), that, consequently, the large amount of modification claimed to have been produced by man is a conceivable and credible result. (F. D.)

BREGENTZ, the ancient *Brigantia*, capital of the circle of Vorarlberg, in Tyrol, stands on a hill at the S.E. end of the Lake of Constance. It has an old castle, two convents, and an orphanage. Silk and cotton are manufac-

[1] *Bull. de la Soc. d'Acclimat.*, tom. vii., 1860, p. 457.

tured, and it carries on an active transit trade. It was long the seat of a Roman garrison, and in the Middle Ages it gave the title to a powerful family of counts, whose territory passed to Austrian possession in the 16th century. In 1646 the town was captured by the Swedes; and in 1850 it gave its name to a treaty by which Austria, Bavaria, and Würtemberg formed an alliance against Prussia. Population in 1869, 3686.

BREHON LAW, the law of Ireland previous to the Conquest, and of some communities of the Irish down to the 17th century (from *breitheam*, genitive *breitheamain*, a judge; root, *breith*, a judgment; compare *Vergobretus*, "*vir-ad-judicandum*," Cæs., *De Bell. Gall.*, i. 16). Three volumes of these laws, comprising the code called the *Senchus Mor*, alleged to have been revised by St Patrick, have been published by a Royal Commission appointed in 1852, and other portions in the second series of O'Curry's *Lectures on the Materials of Ancient Irish History*, edited, with a learned introduction, by Dr W. K. Sullivan in 1873. The antiquated and often obsolete language both of the original text and of the interlined glosses, coupled with the fact that portions of both are cited in compilations considered not later than the 10th century, are arguments for their acceptance as fragments of a primitive system unmodified by Anglo-Saxon, Danish, or Norman influences. The Roman (or civil) law is hardly traceable in them, except as regards ecclesiastical affairs, and that *sub modo* only. From the first-mentioned cause also, the provisions are often obscure and sometimes unintelligible; but enough appears to indicate the general nature and much of the details of these laws.

As compared with the collections known under the generic title *leges barbarorum*, they are remarkable for their copiousness, and furnish a striking example of the length to which moral and metaphysical refinements may be carried under rude social conditions. They present a state of society such as may be conceived to have existed under the older manorial organization, when the land was to a greater extent "folk"-land than "boc"-land, and comprised commons of tillage as well as of pasture. This kind of occupancy entailed annual repartitions of the tillage, recalling the usage of the ancient Germans (Cæs., *Bel. Gall.*, vi. 20), and of which, as practised on a minor scale in Ireland in 1782, Sir Henry Piers has given an account in his description of Westmeath (Vallancey, *Coll.*, vi. p. 115). Traces of such repartitions survived under the name of Rundale (Irish *ranndach*, "partire") in the Highlands of Scotland and in some parts of the West of England till recent times (Maine, *Early Inst.*, p. 101). There is no evidence, however, in the Brehon code, as now published, of merely family occupancy, in which one household living together, or even one village community, enjoyed the land and its produce in common, although such an origin may be theoretically conjectured for the institutions described. The social unit comprised separate families and households numerous enough to occupy a *crich* or *quasi* manor, within which existed a court and complete system of primary social organization. In each of these, mensal lands were set permanently apart for the chief, and means existed by which portions of the common land could, within certain limits, be acquired in severalty by individual owners. The *crich* formed portion of the *tuath*, or *quasi* barony, one or more of which constituted the *mor tuath*, or petty kingdom, equivalent to a county or several counties, governed by a *ri* or *regulus*, who, in theory at least, bore allegiance, through superior *reguli*, to the monarch. The grades of rank were numerous, but the distinctions of wealth which grounded them appear very arbitrary. The upper classes were all "Aires." To be eligible to the *aire* grade, the freeman should possess, besides a certain amount of wealth in cattle, a prescribed assortment of agricultural implements and household goods, the meagreness of which exemplifies the slow progress of the arts of life in early states of society, and he should have a house of given dimensions, ranging from 17 to 27 feet in length, and containing a given number of compartments. The houses were of timber and wattle-work, surrounded by open spaces of prescribed extent for each class. The lower limit for this space was the distance to which the owner seated at his door could throw a missile of given weight; multiples of that distance determined its extent for the higher classes. Tacitus has noticed a like custom of keeping clear spaces round the several dwellings among the early Germans; and this regulation has probably contributed to retard the progress of the early Irish out of pastoral and agricultural into civic habits. There was a serf and slave population, who were designated *ernaans*, as representing the earlier Firbolg and Pictish colonists, who did not enjoy these privileges, except by the process of becoming *fuidhirs* or tenants of the separate lands of the nobles, who called themselves *Gaidel*, or Gael, and claimed a different descent. Besides these tenants, or "feuers," there were dependants called *ceilés*, who stood to the wealthy classes in a relation resembling that of the *clients* of the Roman commonalty to their patrons. Both they and the *fuidhirs* owed suit and homage to their *flaths* or lords, as well as services and rents in kind and in refections. The food-rents, *biadh*, corresponding to the Anglo-Saxon *feorme* (whence "farmer"), were supplied both at the residences of the chiefs and at the tables of their tenants, whence originated the customs of *coyne* and *livery* of later times.

The use of coined money was practically unknown, and the unit of value (*sed*, *seota*, "assets") was the cow. The *ceilés* appear to have been attached to their lords by largesses, or "commendations" of cattle which they used in their own tribal lands. It is in the *fuidhir* class that a law of tenure of land originated, and possibly in these relations we may discover the rudiments of a partly-developed feudalism. The *fuidhir* is, in the theory of the native etymologists, the *fo-tir* or "land-underling," as one who holds land of another. The rules regulating these several kinds of enjoyment of the land are peculiar to the Brehon code, and, as may be observed of all its provisions, are extraordinarily minute, being designed to fix all rights and liabilities, under every probable state of circumstances, in values numbered, which may be one cause for the slow social progress made under their operation. For each supply of cattle to the *ceilé* a definite return to the *airé* is fixed to the end of seven years, when the property vests in the *ceilé*. But the supply should not exceed fixed limits if the recipient would preserve his *status* as a freeman. The *fuidhir*, or base tenant, was bound to larger returns in rent and services, and the lord might, on violation of the tenant's engagements, resume the possession of the land; but it would appear that during the *fuidhir's* occupation he could not be otherwise disturbed without a measure of compensation. On the death of the *ceilé* or of the *fuidhir*, a *quasi* heriot was payable to the lord.

The succession to the territorial headships was elective within hereditary limits; the succession to tribal rights of occupancy, and individual rights of ownership in the separate hereditaments acquirable by individuals, was hereditary. The law of *distribution* of a deceased person's property is very minute in its provisions, though obscure, owing to the technical description of the classes and persons entitled; but it appears to have contemplated divisions *per capita* and not *per stirpes*. The law of *marriage* is remarkable for the variety of irregular relations which it appears to sanction, and for its careful protection of the separate pro-

perty of the irregular as well as of the lawful wife, both during cohabitation and on separation, which appears to have been frequent. The lawful wife seems to have had no other protection against the introduction of the "adaltraich" wife than the withdrawal of her separate property, in addition to certain mulcts payable to her on the occasion. She possessed independent rights of alienating a portion of her separate property, and could, to some extent, control the rights of alienation of her husband. The looseness of the marriage tie evidenced by these laws was one of the evils calling for reform alleged by the Irish prelates in their letter moving Pope Alexander III. to ratify the grant of the island made by Adrian IV. to king Henry II.

The practice of putting out the children of the wealthier classes to be nursed and educated may have contributed to make such relations less incompatible with domestic peace. The law of *fosterage*, of which few if any recognizable traces, outside the law of apprenticeship, have survived elsewhere, provides for the external nursing and educating of the children of the upper class by poorer members of the community, who, besides the fosterage-fee received with the infant, had a claim on the foster-child for support in old age. The fostering began from infancy, and terminated, in the case of daughters, at thirteen, and of sons, at seventeen years of age. A certain amount of instruction should be imparted. Girls of the less wealthy class should be taught to use the handmill (*quern*) and sieve, to bake, and to rear young cattle; those of the higher class to sew, cut out, and embroider. The boys should learn kiln-drying and wood-cutting, and those of the upper class chess-playing, the use of missiles, horsemanship, and swimming. The lawful food for all was porridge. Their clothing, besides the nursing clothes supplied by the parents, was according to their status, from sober coloured stuffs for the children of the less wealthy to scarlet cloth and silks for the children of those of the rank of king. Provision was made for the necessary correction of the pupil, with mulcts for excess. During the pupilage, the foster-father was entitled to all compensation for injuries to his charge, and liable to all mulcts for their offences. If the child died in its pupilage, another might be sent in its place. If returned before the completion of the term, or imperfectly educated, the foster-father should refund. The fixing of the proportionate amounts due in the several cases gives rise to much minute regulation. The law of *military service* like the others, was based on a system of fines leviable for non-attendance and even for desertion in the field. To what has been said on the land-law it may be added that public contributions were leviable for the repair of roads and bridges, and the maintenance of the chief's or king's fortresses; and that each community had a public mill, fishing-net, ferry-boat, &c., besides such objects of this kind as were possessed in severalty by the wealthier members. There was also a law of waifs and strays, and of wrecks of the sea, with provisions for the entertainment of shipwrecked seamen at the common charge of the district entitled to the distribution of the wreck. There is little mention of testamentary disposition; and from the language employed, a Roman origin may be probably surmised for it. To counterpoise the excess of privilege incident to the possession of wealth, the mulcts payable for misfeasances and nonfeasances of all kinds were graduated in the interests of the poorer classes. Crime and breach of contract might reduce from the highest to the lowest grade.

As regards the law of *contracts* generally, the disabilities arising from tribal partnership, infancy, imbecility, coverture, and obligation to the lord give rise to many exceptions and qualifications, the general rule being that acquiescence, after notice, by the parties jointly interested, or standing in relations of protectorship, has the effect of validating what would otherwise be void. Distinct periods are limited within which the parties entitled to disagree may avoid the bargain; and, in all cases, a *locus pœnitentiæ* of twenty-four hours is annexed to the oral agreement, within which time either party may rescind it. The nature and effect of a *warranty* on sale appears also to have been understood and provided for; and frequent reference is made to the cases arising on unsoundness, latent or supervening. There are some traces of a law of the *market*, but how far, if at all, it qualified the ordinary rules of contract, does not appear. The *Aenachs*, or great fairs, were held at distant places and at long intervals of time. Various immunities are given to the persons frequenting them; and a violation of some of the necessary provisions for securing the peace and decorum of the meetings was exceptionally punishable with death, while almost every other offence might be condoned by a pecuniary payment. A highly interesting account of one of these great assemblages, which was held triennially at Carman, near Wexford, is given in a tract translated in the 2d series of O'Curry's *Lectures*, where, among the various classes resorting there for amusement and traffic, mention is made of Greek merchants bringing commodities for sale. The laws themselves give little intimation of their own origin or sanctions. They appear to have undergone no substantial changes from time immemorial; but some evidence exists of local law-making authority exercised at meetings of the freemen of the *crich*, subject to revision by some higher authority, and one of the objects of these fairs or *comitia* was to publish such enactments as well as the general body of the laws and customs from time to time. The law of *torts* regarded all offences, with the nominal exception of murder, as condonable by fines until the offender and those liable for him could pay no more, when the defaulter lost his *status* and fell into the servile class. For some of the offences of the individual, the *finnê* or family were responsible; for others, particular sureties. Whether this system of *quasi* frank-pledge did not extend to breaches of contract, as well as to cases of non-feasance, misfeasance, and breaches of the peace, appears uncertain. The scale of mulcts for the several sorts of homicides, wounds, and personal hurts, is in outline the same with those of the other western European nations; but, in addition to their definite fine of so much for such and such a lesion or bruise, it provides by rateable deductions for excusatory circumstances of intention, knowledge, contributory negligence, accident, and necessity, all of which are considerable refinements on the contemporaneous systems of the Continent. The penalty of death for murder was of ecclesiastical introduction, and, like the law ordaining the payment of tithes, appears to have fallen into desuetude before the Conquest. Chief Baron Gilbert, in Dwyer's case (Gilb., *Ev.*, vol. i. p. 9) has an observation apposite to the state of society disclosed by this system of measured mulcts and mutual suretyship, in treating of the state of Britain before murder had become punishable with death under the later law of Canute:—

"It is not very hard to conceive how the kingdom was maintained by *pecuniary mulcts* only; for in those days every man was put in the *Decenna* (tything); and if found wandering three days out of the *Decennary*, he was taken up and imprisoned, and he was presently to abjure the kingdom, or else he lay at the mercy of every one that could lay hands on him. And if any offence was committed in any of the *Decennaries*, if the party was brought to answer, he was obliged to pay his fine for his offence, or he was *imprisoned* for ever; and, if he fled, the *tything* was answerable for his fine or mulct to the king. So that by this discipline men were put under a necessity of being innocent, or paying a grievous fine, or being totally deprived of the conversation of mankind. And the laying of the fine on the tything, in case the offender fled, made it the interest of every man to bring the offender to light, and made it exceeding difficult to conceal a theft or a murther."

Imprisonment, among the Irish at the period of these laws, does not appear as detention in a common gaol, but as a personal fettering of the culprit; and some of their subtlest distinctions concern the liability of the person bound to provide the fetters, in case of the culprit's escape. It has been suggested with much appearance of reason, that refinements of this kind, *inter apices juris*, with which the Brehon law abounds, are rather exercises of the writer's ingenuity in framing suppositional cases illustrating classes of abstract rules than evidences of any actual application of law to the particular subjects. Such are the law of the measure of damages for injuries by bees, by cats, by the hunting hound, by traps for game, &c., all which are elaborated to a pedantic nicety. Of the *courts* in which these laws were administered we have but an imperfect view. The primary local tribunal was a *quasi* court baron, called the *Airecht*, composed of freemen of a certain status. The inferior classes were *écoma airechta*, that is, "impares curiæ." The office of Brehon in the court is very obscurely indicated. The stays and imparlances (*anad, esain, dithim*), &c., incident to the process of bringing causes to final judgment, and the fact that damages were, in all cases of ordinary occurrence, assessed beforehand by specific rule, gave repeated opportunities for settling out of doors. There were professional advocates and means of carrying the case to courts of higher jurisdiction, but how these were constituted does not appear; but mention is made of several gradations from the *airecht urnaidh* (sheriff's *tourns?*) to the *cul-airecht*, or ulterior court, which indicates some resort by way of appeal. Their rules of *evidence*, in addition to the testimony of the eye, admitted, in questions of title to land, that of the ear, *cluais*, or general report, and *laidh* (*cantus*) or history in the form of a poem publicly recited (a remarkable example of practical functions belonging to the office of a bard) as well as the evidence of landmarks or mearing stones. These, it seems (O'Curry, 2d series, Sullivan, Introd., clxxxvii.), should be sunk under the surface, as Martin in his account of the Western Isles of Scotland (p. 114) has described:—

"They preserve their boundaries from being liable to any debates by their successors, thus. They lay a quantity of the ashes of burnt wood in the ground, and put big stones above the same; and for carrying the knowledge of this to posterity, they carry some boys from both villages next the boundary and then whip 'em soundly and tell it to their children. A debate having arisen between the villages of Ose and Groban in Skye, they found ashes as above mentioned under a stone, which decided the controversy."

This gives countenance to the tradition that, prior to the reign of Aed Slaine in the 7th century, there were no fences in the country, but all was open save the walls and mounds surrounding dwellings. It is difficult to accept this statement unreservedly, partly on account of the habit of assigning fabulous origins indulged by all archaic, and notably so by the Irish writers, but chiefly because the Brehon code comprises a very full law of *fences*. The materials, dimensions, and several sorts of quick-setting of these are laid down with great particularity, and the rights and liabilities of adjoining owners are minutely described. Returning to the subject of judicial administration, we have a much clearer view given of the nature and incidents of *process* by which the jurisdiction of the court was made to attach, than of the constitution of the court itself. This was by *distress*, or the seizure of the goods of the defendant, in some cases immediate, in others preceded by summons, and, in the case of the privileged classes, by *trosgad* or fasting on the part of the plaintiff, a practice still known in some parts of India, and much relied on as an evidence of common Aryan origin for the ancient Irish and present Hindu legal systems. The distress might either remain in the hands of the defendant, if of the superior grade, by way of attachment (*fornasc*), subject to a lien. on security for his appearing and abiding the award of the court, or it might at once be driven to a pound (*forus*). Here it was kept during a certain time or "stay" (*anad*), varying with the nature of the complaint, during which the defendant might have it back on like security. Failing this, a process of forfeiture (*lobad*) commenced, and ultimately the distress, or so much of it as sufficed to satisfy the claim, vested in the plaintiff, the defendant receiving back the balance, if any. On security being given, the merits of the dispute were determined by the court. A proceeding analogous to the action of *replevin* was thus incidental to every litigation; and this appears to have been the early course of the common law in all the local courts, not proceeding on the king's writs, both of England and Scotland, down to the times of Bracton (fo. 156. 2, Reeves's *Hist. Eng. Law*, 59), and of the enactment "*Quoniam attachiamenta*" (*Leges Bar. Scot.*, i. and cxi.). One of the few *cases* cited in the Brehon law (vol. i. p. 65) states the procedure in what was substantially an inter-tribal action of ejectment for recovery of land, in the incidents of which a resemblance is found to many principles of jurisprudence and methods of procedure of the common law of England, such as prescription, limitation, set-off, entry, ouster, distress, rescue, fresh pursuit, withernam, replevin, surety in replevin, avowry, Welsh mortgage, writ of possession, and return of distress. The case was this:—

Land had been assigned by way of Welsh mortgage in part payment of a mulct or fine. The mortgagee and his descendants remained in possession until it became a question whether the law of prescription (*rudrad*) had not given them the absolute estate. To try the title, a bailiff of the claimant tribe put his horses on the land. The bailiff of the tribe in possession drove them off, accompanying the act with an admission that formerly the claimant tribe had been in possession. The claimant's bailiff then distrained three cows of the occupier's bailiff outside his cattle shed, and drove them to the border of the territory, where they lay down. It would have been his duty here to give public notification of his proceedings, and to have driven his distress to the nearest pound of the external territory; but the cows, not having been milked, escaped, and returned to their calves, which had been left behind. The distrainer, making fresh pursuit by the traces of the milk dropped on the ground (regarded probably as a constructive keeping in view), recaptured them at daybreak at the homestead of the owner, and, with them, in addition, distrained and impounded three [six (]] others, taken from [out of] the door of the cattle-shed, by way of *aitherach gabail*, or second caption, to double the amount for what seems to have been considered a constructive rescue implied by the escaped beasts being again in the owner's custody. Notwithstanding these facts, the regularity of the proceeding was admitted by the tribe in possession, whose *regulus* now came forward and had back the distress, on giving pledges to try the question at law, and to return the cattle if unsuccessful. Further security was also given by him for some other liability. The action which, so far, was in the nature of replevin, now assumed the character of ejectment, and the personal wrong of ousting the bailiff who had made the entry merged in the question of title to the possession of the land. It was held that the period of prescription, being the time of three successions to the kingship, had not expired, one of the successions being irregular. The land was, therefore, still redeemable, and, on taking an account and setting off the receipts, including a mulct of less amount due by the mortgagee, against the original balance due to him, it was found he had been fully paid, and a return of the cattle was awarded, and possession of the lands delivered to the claimant. (See "On the Rudiments of the Common Law discoverable in the published portion of the *Senchus Mor*," in *Trans. Roy. Irish Academy*, vol. xxiv. p. 83, 1867.)

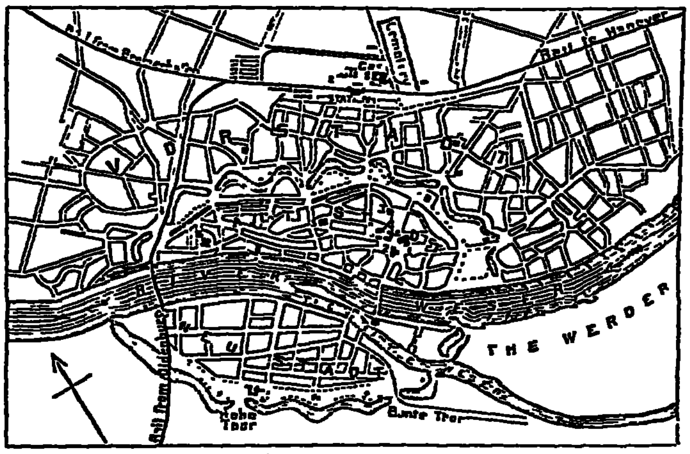
It appears from this that the provisions of the statute of Marlbridge (52 Henry III. c. 4) in England, forbidding the driving of distresses beyond the bounds of the county, and of the "Regiam Majestatem" (re-enacted by 1 Robert, i. c. 7) in Scotland, requiring that when driven beyond the bounds of the territory the distress shall be exhibited before witnesses, are to be regarded not as merely introductive enactments, but as substantially declaratory of the previous state of the common law; further, that the old opinion that "all administration of justice was at first in

the king's hands, but afterwards, as the kingdom was divided into counties, hundreds, &c., so the administration of justice was distributed among divers courts, of which the sheriff had the government of the county court, &c.," is probably grounded on an inversion of the actual progress of the facts; and that when it is said of the right to recover land in a personal action, of set-off, and of other equitable incidents of justice, that such rights did not exist at the common law, the words "in actions commenced by original writ," should probably be understood; for there is no difficulty in conceiving how all the main incidents and principles of law disclosed by the Irish case could have arisen regularly in the county court, always a court of equity for the defendant, when the bishop was associated with the sheriff, and the right of the suitor to be his own apparitor had not yet been abrogated by the law of Canute, re-enacted by William I. (*Leg. Gul. Conq.*, xliv.). How these resemblances have come to exist in the early laws of the two islands may be a question for the historian and ethnologist. It is well to know that, whencesoever derived, the common law may to so great an extent be recognized as substantially a common inheritance of all the populations now organized into the United Kingdom. (S. F.)

BREISLAK, SCIPIONE, an eminent geologist, was born at Rome in 1748. He early distinguished himself as professor of mathematical and mechanical philosophy in the college of Ragusa; but after residing there for several years he returned to his native city, where he soon became a professor in the Collegio Nazareno, and began to form the fine mineralogical cabinet in that institution. His leisure was dedicated to geological researches in the Papal States. His account of the aluminous district of Tolfa and adjacent hills, published in 1786, gained for him the notice of the king of Naples, who invited him to inspect the mines and similar works in that kingdom, and appointed him professor of mineralogy to the Royal Artillery. The vast works for the refining of sulphur in the volcanic district of Solfatara were erected under his direction. He afterwards made many journeys through the ancient Campania to illustrate its geology, and published in 1798 his *Topografia Fisica della Campania*, which contains the interesting results of much accurate observation. Breislak also published an essay on the physical condition of the seven hills of Rome, which he regarded as the remains of a local volcano,—an opinion which more recent investigations appear to disprove. The political convulsions of Italy in 1799 brought Breislak to Paris, where he remained until 1802, when, being appointed inspector of the saltpetre and powder manufactories near Milan he removed to that city. He died on the 18th of February 1826.

During the latter part of his career he published the following works:—*Del Salnitro e dell' Arte del Salnitraio*; *Memoria sulla Fabbricazione e Raffinazione dei' Nitri*; *Instruzione pratica per le piccole Fabbricazione di Nitro, da farsi dalle persone di Campagna.* His valuable *Introduzione alla Geologia* appeared in 1811; a French edition with additions was published in 1819. Finally, the Austrian Government, in 1822, took on itself the expense of publishing his *Descrizione Geologica della Provincia di Milano.*

BREMEN, one of the three free cities of the new German empire, is situated on the River Weser, about 50 miles from the sea and 60 S.W of Hamburg. The latitude of the observatory is 53° 4′ 36″ N., and the longitude 8° 48′ 54″ E. The city consists of three parts—the old town (*Alt Stadt*) and its suburban extensions (*Vorstadt*) on the right bank of the river, and the new town, dating from the Thirty Years' War, on the left. The river is crossed by three bridges, of which the last was built in 1874–5. The ramparts of the old town have long been converted into beautiful promenades and gardens, but both the old and the new town are still surrounded with moats. The area of the whole city is great in proportion to its population, the houses in general being built to contain only one family. The public buildings, situated chiefly in the old town, comprise the following:—the cathedral, erected in the 12th century, on the site of Charlemagne's wooden church, and famous for its *Bleikeller*, or lead-vault, in which bodies may be kept a long time without suffering decomposition; the church of St Ansgarius, built about 1243, with a spire 400 feet high; the *Rathhaus*, a building of the early part of the 15th century, with a celebrated underground wine-cellar; the town-house, formerly the archiepiscopal palace, and converted to its present uses only in 1819; the Schütting, or merchant's hall, originally built in 1619 for the guild of cloth-traders; the exchange, completed in 1867; the theatre; the town library; the high-school, a quite recent erection; and the new post-office buildings. St Rembert's church and the colosseum may be mentioned in



Plan of Bremen.

1. Cathedral. 2. Exchange. 3. Museum. 4. Rathhaus. 5. St Ansgarius. 6. St Stephan

the Vorstadt; and the barracks in the new town. At the head of the monetary establishments stands the *Bremer Bank*, which was founded in 1856 as a private speculation, and is only allowed to issue notes to the amount of its realized capital. Seven other banks were in operation in the beginning of 1875. There are in the city eighteen public and thirteen private schools, the former including a navigation and an industrial school, and the latter an institution for the extension of female labour.

New waterworks, constructed by an English company on the left side of the river, were opened in 1872, and supply the city with water of a good quality from the Weser; a large fire-brigade establishment has also been founded in imitation of a similar institution at Berlin; and an extensive park, the *Bürger Park*, has been laid out in the old Bürger Weide, or meadows. Railway communication is rapidly increasing, and a central terminus for all the lines is proposed. The most important of those already open connect the city directly with Hanover, with Oldenburg, with Bremerhaven, with Hamburg, and with Minden. The manufactures of Bremen are of considerable extent and variety, the most important being those of tobacco, snuff, and cigars, though they have somewhat declined since the formation of the empire. In 1872 no fewer than 2500 people were employed throughout the state in preparing cigars alone, while the making of cigar-boxes occupied 250 more. The shelling of rice is also largely carried on, and there are sugar-refineries, soap-works, shipbuilding-yards, sail-cloth factories, a large iron foundry, distilleries, asphalt-works, and colour-factories. In the extent of its foreign trade Bremen is one of the chief cities in Germany, and as a port of emigration it is only rivalled by Hamburg. It deals largely with the United States, Great Britain, British India, and Russia. Its principal imports consist of cotton, tobacco, coffee, rye, rice, coals, iron goods, petroleum, glass, hides and skins, silk, wool, linen, and dyes,

and its exports of many of these articles in a manufactured state. In 1874 the arrivals were 3407 vessels, with a register of 990,101 tons,—650 belonging to Bremen, 418 to Britain, and 317 to Holland. Much of the shipping trade of the city is conducted at Bremerhaven and Vegesack, because vessels drawing more than 7 feet cannot get up to the town. Among the societies of the city are a nautical association, the German Life-Boat Institution, and the chamber of commerce.

As early as 788 Bremen, then a mere fishing village, was made the seat of a bishopric by Charlemagne; and in 858 it was raised to an archbishopric by Ansgarius, archbishop of Hamburg, who had been driven from that city by the Normans about 847. The importance of Bremen soon increased; and its citizens took an active share in the more remarkable movements of the time, such as the Crusades, the establishment of the Teutonic Order, and the founding of Riga. In 1283 they joined the Hanseatic League, and in 1289 formed a treaty with Gisalbert, their archbishop, by which he agreed to confine himself to the spiritual affairs of his diocese, leaving secular concerns to the civic authorities. In the course of the 14th century, there was much intestine conflict in the city, and in the 15th it had to defend its commerce against the pertinacious hostility of the Frisian pirates; but from both perils it issued with increased vigour. About 1522 the archbishop and most of the inhabitants declared for Protestantism, in defence of which they took a foremost part, and had on various occasions to suffer severely. The city was twice besieged by the imperial forces in 1547. At the peace of Westphalia (1648) the archiepiscopal diocese was secularized and raised to a grand duchy, which was ceded to Sweden. In a war between Denmark and Sweden in 1712 it was conquered by the former, and in 1715 it was purchased from that power by Hanover along with the duchy of Verden. The transfer was confirmed by the diet of 1732, and the district now forms part of the Hanoverian province of Stade. The city of Bremen had meanwhile had its civic rights more or less thoroughly recognized during these vicissitudes. In 1806 it was taken by the French, and from 1810 to 1813 it was the capital of the department of the Mouths of the Weser. Restored to independence by the congress of Vienna in 1815, it subsequently became a member of the German confederation, and in 1867 joined the new confederation of the North German States, with which it was merged in the new German empire. It has now one vote in the federal council, and sends a representative to the imperial diet. The freedom of its port is secured, and in compensation it pays an *aversum* of 250,000 thalers to the customs union.

The territory of Bremen has an area of 63,400 English acres, about 5000 acres being occupied by the towns of Bremen, Bremerhaven, and Vegesack, and about 1200 by the bed of the Weser. Of the remaining area about two-fifths are arable land and two-fifths meadowland, the extent of woodland being very slight. The soil is for the most part sandy, though here and there marshes or bogs occur. Of the population, which in 1873 was 130,871, 88,146 were inhabitants of Bremen the city, 12,129 of Bremerhaven, and 3843 of Vegesack, and 26,753 of the rural districts. With the exception of about 2800 Roman Catholics and 271 Jews, the inhabitants are Lutherans or Calvinists of various denominations. According to the constitution of 1849, modified by various enactments in 1854, the senate, which is the executive power, is composed of eighteen members, elected by the "burghership" on presentation by the senate. Of these, ten at least must be lawyers, and five merchants; and two of the number are nominated by their colleagues as burgomasters, who preside in succession, and hold office for four years, one retiring every two years. The burghership consists of 150 (formerly 300) representatives chosen from the citizens for six years. Sixteen are elected by those of the inhabitants of the city who have attended a university, 48 by the merchants, 24 by the manufacturers and artisans, and 30 by the other citizens; of the remaining representatives 6 are furnished by Bremerhaven, 6 by Vegesack, and 20 by the country population. The revenue in 1873 amounted to £545,531, and the expenditure was £1,094,222, so that the deficit was £548,691. The total debt at the end of the year was £3,676,738. The territory and city are still outside the limits of the customs union. In the whole state there were in 1870 forty-five public and thirteen private schools, with a total attendance of 12,794.

BREMER, Fredrika, the most celebrated Swedish novelist, was born near Abo, in Finland, on the 17th August 1801. Her father, a descendant of an old German family, was a wealthy iron master and merchant. He left Finland when Fredrika was three years old, and after a year's residence in Stockholm, purchased an estate at Arsta, about 20 miles from the capital. There, with occasional visits to Stockholm and to a neighbouring estate, which belonged for a time to her father, Fredrika passed her time till 1820. The education to which she and her sisters were subjected was unusually strict; their parents, especially their father, were harsh and took little or no pains to understand the temperaments of the children. The constant repression, the sense of being misunderstood, and the apparent aimlessness of such an existence told with greatest force upon Fredrika, who was of a quick and eager disposition, fond of praise and conscious of powers which it seemed to her must lie for ever unused. She felt as if her life were being wasted; there was nothing on which she could expend her energy; no career was open to a woman. Her health began to give way; and in 1821 the whole family set out for the south of France. They travelled slowly by way of Germany and Switzerland, and returned by Paris and the Netherlands. It was shortly after this time that Miss Bremer became acquainted with Schiller's poetical works, which made a very deep impression on her. Her home life, however, was still unsatisfying, and in her passionate longing for some work to which she could devote herself, and through which she might do some good in the world, she for a time resolved to join one of the Stockholm hospitals as a nurse. This plan was given up on the entreaty of her sister. Meanwhile, she had found relief for her pent-up feelings in writing, or rather in continuing to write, for she had been an authoress of a sort from the age of eight. In 1828 she determined to attempt publication, and succeeded in finding a publisher. The first volume of her *Sketches of Every Day Life* (1828) at once attracted attention, and the second volume (1831), containing one of her best tales, *The H—— Family*, gave decisive evidence that a real novelist had been found in Sweden. The Swedish Academy awarded her their smaller gold medal, and the fortunate authoress became famous. From this time Miss Bremer had found her vocation. Her father had died in 1830, and her life was thereafter regulated in accordance with her own wishes and tastes. She lived for some years in Norway with a friend, after whose death she resolved to gratify a long-repressed desire for travel. In the autumn of 1849 she set out for America, and after spending nearly two years there returned through England. The admirable translations of her works by Mary Howitt, which had been received with even greater eagerness in America and England than in Sweden, secured for her a warm and kindly reception. Her impressions of America, *Homes in the New World*, were published in 1853, and were at once translated into English. After her return Miss Bremer devoted herself to her great scheme for the advancement or, one may say, emancipation of women. On this subject she had thought deeply, and her own experience was of value to her in shaping her ideas of what the education and function of woman should be. "She wished," says her sister, "that women should, like men and together with them, be allowed to study at the elementary schools and academies, in order to gain an opportunity of obtaining suitable employments and situations in the service of the state. . . . She said she was firmly convinced that women could acquire all kinds of knowledge just as well as men, that they ought to stand on the same level, and that they ought to prepare themselves in the public schools and universities to become lecturers, professors, judges, physicians, and functionaries in the service of the state" (*Life*, &c., pp. 81–2). Some of these views were expounded in her later novels, *Hertha* and *Father and Daughter*, which naturally were not so successful as her other works. Miss Bremer not only wrote of her plans, but endeavoured, so far as she could, to induce women to devote themselves to some kind of work. She organized a society of ladies in Stockholm for the purpose of visiting the prisons, and during the cholera raised a society the object of which

was the care of children left orphans by the epidemic. In 1856 she again travelled, and spent five years on the Continent and in Palestine. Her reminiscences of these countries have all been translated into English. On her return she settled at Arsta, where, with the exception of a visit to Germany, she spent the remaining years of her life. She died on the 31st December 1865. Miss Bremer has been called, and with justice, the Miss Austen of Sweden. Her novels have the purity, simplicity, and love of domestic life, which are characteristic of the English writer. She is, however, inferior to Miss Austen in construction of plot and in delineation of character. Some of her best works show slight traces of overstrained sentiment, and the situations are occasionally somewhat melo-dramatic. *The Neighbours* is the most popular and the best of her tales; it is an admirable picture of Swedish home life, showing at times the quiet humour which is more prominent in *The H—— Family*. All the works have been translated into German and English, and the greater number of them into French. In America they have circulated very widely, and have been extremely popular.

See *Life, Letters, and Posthumous Works of F. Bremer*, by her sister, translated by Milow, London, 1868.

BREMERHAVEN, a seaport town belonging to the free city of Bremen, on the right bank of the Weser at the mouth of the Geest, in 53° 32′ N. lat. and 8° 34′ E. long. It is built on a piece of ground surrendered to Bremen in 1827 by Hanover, and increased by treaty with Prussia in 1869. The port was opened in 1830, and there are now, besides an excellent harbour, four large wet docks, five dry docks, hydraulic cranes, and lines of railway running along the quays. The entrance is free from ice nearly all the year round, even when the other ports of the neighbouring coasts are closed, and vessels drawing 22 feet can enter safely. The town is rapidly extending and will soon be united with Geestemünde. Among its public buildings the most remarkable is the great hospitium for emigrants, erected in 1830, which can accommodate 2500 persons. The Hanoverian fort and batteries, which formerly protected the town, have been removed, and their place is supplied by similar works farther down. The population, which in 1850 was only 3500, amounted in 1871 to 10,596.

BRENNUS, the name given in history to two kings or chiefs of the Celtic Gauls, probably not an appellative, but a title, the Cymric "*brenhin*"=king. (Dr Pritchard thinks it more probably the equivalent of the Welsh proper name "*Bran*.") The first Brennus crossed the Apennines into Italy, at the head of 70,000 of the tribe of Gauls known as Senones, and ravaged Etruria, 391 B.C. Some envoys from Rome, sent to watch their movements, were said to have taken an active part in a skirmish before the walls of Clusium; and the Gauls, failing to obtain the surrender of these men, marched at once for Rome. A Roman army of about 40,000 men was hastily despatched to meet them, and took up a position on the banks of the little river Allia, within twelve miles of the city. Here Brennus attacked and defeated them with great slaughter; and if he had pressed on at once, Rome would have lain at his mercy; for the greater part of the beaten army had placed the Tiber between themselves and the conquerors. But the Gauls lingered on the field of battle, mutilating the dead, and drinking to excess. The Romans gained time to occupy and provision the Capitol, though they had not force sufficient to defend their walls; their women and children were sent off to Veii; and when on the third day the Gauls marched in and took possession, they found the city occupied only by those aged patricians who had held high office in the state. Too old to be of service in the little garrison, and too proud to fly, they had all solemnly devoted themselves to death, and sat each in the porch of his house, in full official robes, awaiting the invaders. For a while these withheld their hands from them, out of awe and reverence; but the ruder passions soon prevailed, and they were all slaughtered. The city was sacked and burnt; but the Capitol itself withstood a siege of more than six months, saved from surprise on one occasion only by the wakefulness of the sacred geese and the courage of Marcus Manlius. (See MANLIUS.) At last the Gauls consented to accept a ransom of a thousand pounds of gold. As it was being weighed out the Roman tribune complained of some unfairness. Brennus at once threw his heavy sword into the scale; and when asked the meaning of the act, replied that it meant "*Væ victis*"—"the weakest must go to the wall." The Gauls returned home with their plunder, leaving Rome in a condition from which she took long to recover. A later legend, most probably an invention, represents Camillus as having suddenly appeared with an avenging army at the moment when the gold was being weighed, and having defeated and cut to pieces Brennus and all his host (Livy, v. 49).

The second Celtic chief who bears the name of Brennus in history is said to have been one of the leaders of an inroad made by the Gauls from the east of the Adriatic into Thrace and Macedonia, 280 B.C., when they defeated and slew Ptolemy Ceraunus, then king of Macedonia. Whether Brennus took part in this first invasion or not is uncertain; but its success, and the rich spoils brought home, led him to urge his countrymen to a second expedition, when he marched with an army of 150,000 foot and 60,000 horse through Macedonia, defeating such forces as were brought against him, and passing thence into Thessaly, ravaging as he went, until he reached the historic pass of Thermopylæ. To this point the united forces of the Northern Greeks—Athenians, Phocians, Bœotians, and Ætolians—had fallen back; and here the Greeks a second time held their foreign invaders in check for many days, and a second time had their rear turned, owing to the treachery of some of the natives, by the same path which had been discovered to the Persians two hundred years before. Their land force, however, succeeded in getting on board the Athenian fleet, which was lying off the shore to co-operate with them. Brennus and his Gauls marched on to attack Delphi, of whose sacred treasures they had heard much. But the little force which the Delphians and their neighbours had collected—about 4000 men—favoured by the strength of their position, made a gallant and successful defence. With or without the help of Apollo, who is said to have come to the aid of his sanctuary, they rolled down rocks upon the close ranks of their enemies as they crowded into the defile, and showered missiles on them from their vantage ground. A thunderstorm, with hail and intense cold, increased their confusion, and when Brennus himself was wounded they took to flight, pursued by the Greeks all the way back to Thermopylæ. Brennus killed himself, "unable to endure the pain of his wounds," says Justin; more probably determined not to return home defeated. Few of the invading force eventually escaped.

BRENTANO, CLEMENS, German dramatist and novelist, was born at Frankfort-on-the-Maine in 1777. His sister Elizabeth was the well-known Bettina von Arnim, Goethe's correspondent. He studied at Jena, and afterwards resided in Heidelberg, Vienna, and Berlin, leading a somewhat restless and unsettled life. In 1818 his disgust with all mundane affairs reached such a height that he withdrew from ordinary life and lived in the strictest seclusion at Dülmen. This continued for six years; the latter part of his life he spent in Ratisbon, Frankfort, and Munich. He died at Aschaffenburg 28th July 1842. Brentano belongs to the romantic school of German poetry, and his works, like all others of that class, are marked by excess of

fantastic imagery and by abrupt, bizarre modes of expression. His first published writings consisted of satires and poetical dramas (*Satiren und Poetische Spiele*, 1800); of his later dramas the best are *Ponce de Léon*, 1804, and *Victoria*, 1817; of his poems the best is *Die Gründung Prags*, 1816. On the whole his finest work is the short tale, or novelette, *Geschichte vom braven Kaspar und dem schönen Annerl*, a very perfect little piece, which has been translated into English. Brentano also assisted Ludwig Achim von Arnim, his brother-in-law, in the collection of the tales and poems forming *Des Knaben Wunderhorn*, 1806–8. The collected works appeared at Frankfort in 1852.

BRENTFORD, a town of England, in the county of Middlesex, 8 miles west of London, on a loop line of the South-Western Railway, in 51° 28′ N. lat. and 0° 20′ W. long. It is divided by the River Brent into two parts, known as Old and New Brentford (the former the larger of the two), and is separated from Kew by the Thames. The Grand Junction Canal joins the Brent some miles further up, so that the town has extensive water communication, and is enabled to maintain a considerable trade. Among its manufacturing establishments are gin-distilleries, a brewery, malt-kilns, soap-works, saw-mills, and colour-works. The Grand Junction Water-works, which supply the west end of London, are stationed here, the great stand-pipe, 226 feet high, forming a striking tower-like structure. Market-gardening is largely carried on in the neighbourhood, and there is a weekly market which dates from the time of Edward I. The elections for the county of Middlesex are held in the town. Its population in 1871 was 11,091.

In 1016 Brentford, or, as it was often called, Braynford, was the scene of a great defeat inflicted on the Danes by Edmund Ironside. In 1280 a toll was granted by Edward I. for the construction of a bridge across the river, and in the reign of Henry VI. a hospital of the Nine Orders of Angels was founded near its Western side. In 1642 a battle was fought here between the royalists and the parliamentary forces, for his services in which the Scotsman Ruthven was made earl of Brentford, a title afterwards conferred on Marshal Schomberg. Brentford was during the 16th and 17th centuries a favourite resort of the London citizens; and its inn of the Three Pigeons, which was kept for a time by John Lowin, one of the first actors of Shakespeare's plays, has been frequently alluded to by the dramatists of the period. We have also Shakespeare's "Fat Woman of Brentford" in the *Merry Wives of Windsor*, "Gillian of Brentford" in *Westward Ho*, and various other references in old plays. Thomson, in his *Castle of Indolence*, refers to the pigs for which the town was formerly famous—

"E'en so through Brentford town, a town of mud,
An herd of bristly swine is pricked along."

The two kings of Brentford, so well known from Cowper's allusion, seem to owe their mythical existence to Buckingham's *Rehearsal*, where Bayes prides himself on the skill of his plot, in which he supposes "two kings to be of the same place, as for example at Brentford." See *Athenæum*, 1847, p. 1196; and *Notes and Queries*, 2d ser. vol. viii.

BRESCIA, or BRESCIANO, a province of Italy, in Lombardy, bounded on the N.W. by Bergamo, N.E. by Tyrol, E. by Verona, from which it is separated by the Lago di Garda, S.E. by Mantua, and S.W. by Cremona. Its area is rather more than 1643 square miles. The northern part, or about one-third, is occupied by a chain of mountains which belong to the Rhætian Alps; the remainder forms part of the great plain of Lombardy, and shares in its general fertility. The principal rivers, all tributaries or sub-tributaries of the Po, are the Oglio, the Mella, and the Chiese. Corn, flax, hemp, the olive, and the vine are extensively cultivated, and in some districts the traveller passes for miles through the midst of orchards. The mountainous parts, and especially the valley of Trompia, yield iron, copper, marble, alabaster, and granite. The manufactures consist principally of silk, woollen, linen, and cotton goods, iron, steel, and copper wares, glass, and paper. Among the principal townships are Rovato, Chiari, Orzinuovi, Monte-Chiaro, Salo, and Ponte-vico. Population in 1871, 456,023.

BRESCIA, the capital of the above province, is situated between the Mella and the Garza, about 155 miles by rail from Turin, in 45° 32′ N. lat. and 10° 14′ E. long. It lies at the foot of a spur of the Alps, on the summit of which is a fine old castle formerly known as the Falcon of Lombardy. The town is well built, has fine arcaded streets, and compares favourably in point of cleanliness with other cities in the North of Italy; but it has hardly so many buildings of first-class importance. The old cathedral, a remarkable specimen of the circular form, is sadly disfigured and neglected, and the new cathedral by its side (1604–1825), though built of white marble, is of little architectural merit, St Afra and San Francesco being more worthy of notice. The Broletto, or old palace of the republic, dating originally from the 12th or 13th century, is a large and interesting building; but it has suffered greatly by successive alterations. The episcopal palace contains an extensive public library, consisting principally of the books and manuscripts—many of great antiquity and value—bequeathed to the city by Cardinal Quirini in 1750. There is an exceptionally rich collection of both mediæval and classical antiquities, preserved in a beautiful Roman building, usually known as the Temple of Hercules, built by Vespasian and excavated in 1822; and throughout the numerous churches and mansions of the city are to be found many of the masterpieces of Italian art. Among the other buildings are the Loggia or communal palace erected in 1508, a theatre, a hospital, a lyceum, and various public fountains. The botanical gardens are worthy of notice. Brescia is a busy town. Its arms and cutlery have been famous for centuries; whole streets are occupied by coppersmiths; silk, woollen, and linen goods, paper, leather, and oil are manufactured; and an extensive transit-trade is carried on. The population in 1871 was 38,906.

Brescia, the ancient *Brixia*, is supposed to have been founded by the Etruscans. It was afterwards a town of the Cenomani, and, finally, a Roman free town. After the fall of the empire it was several times pillaged by the barbarians, especially by Attila in 452. From the Lombards, under whom it was the capital of a duchy, it passed to the Franks. It was made a free imperial city by Otho the Great, and shared and suffered in the contests between the Guelfs and Ghibellines. It then fell into the power of the Signiors of Verona, and in 1378 into the hands of the Milanese. It was taken in 1426 by Carmagnola the Venetian general; besieged by the Milanese general Picinino in 1483, but assigned to the Venetians by Pope Martin V.; surrendered by the inhabitants to the French after the battle of Agnano (1509); taken in 1512 by the Venetian general, Andrea Gritti; delivered by Gaston de Foix; and besieged again in 1573, 1575, and 1576. It remained under the Venetian dominion till the dissolution of the republic. It was the capital of the department of Mella during the existence of the Cisalpine republic and the Napoleonic kingdom of Italy, and fell in 1814 under the yoke of Austria. In the revolution of 1849 the inhabitants rose in arms, but were overpowered, after a destructive siege, by the troops of Haynau. In the war of 1859 it again sided with the patriotic party, and followed the destinies of the rest of Lombardy. Brescia has at various times suffered severely from pestilence and epidemics. It was the birthplace of Tartaglia the mathematician and the writer Mazzuchelli.

BRESLAU, a city of Prussia, capital of the government of Silesia, is situated mainly on the left but partly also on the right bank of the Oder, at the influx of the Ohlau, and on the railway from Berlin to Vienna, 190 miles S.E. of the former city. The latitude of the observatory is 51° 6′ 56″ N., and its longitude 17° 2′ 18″ E. The city consists of a new and an old town, and a number of extensive suburbs stretching out in all directions. The fortifications, which were dismantled shortly after 1813, have given place to beautiful promenades; and even in the older parts of the town, where the streets are generally narrow, there are

several open spaces of considerable area. The old cathedral (founded in the 12th century, and recently restored), the Catholic church of the Holy Cross, the Protestant church of St Elizabeth—with its lofty tower, the Jewish synagogue, and the bishop's palace are the principal ecclesiastical buildings. The *Rathhaus* (a fine specimen of

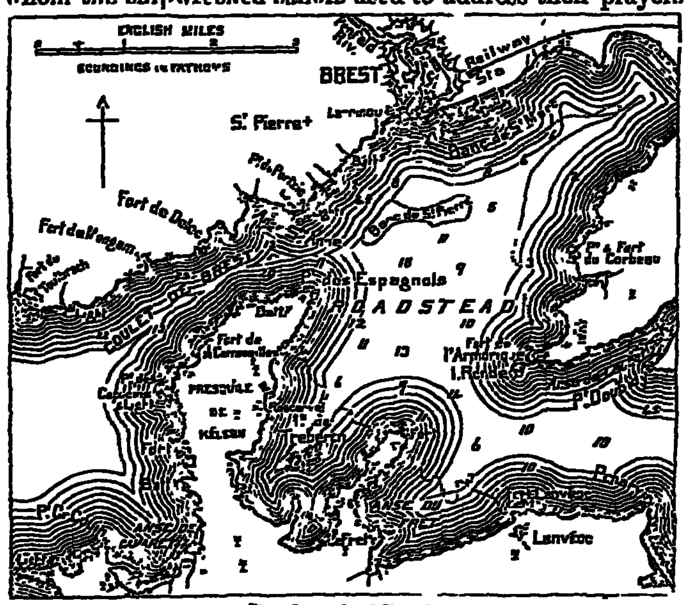
the architecture of the 14th century), the townhouse (of quite recent erection), the royal palace (now used as the Government buildings), the chamber of the states, the exchange, the barracks, the theatre, the post-office, and the new court-house and prison are the more important of the secular structures At the head of the educational institutions for which Breslau is celebrated stands the university, which was founded in 1702 by Leopold I. as a Jesuit college, and was greatly extended by the incorporation of the university of Frankfort-on-Oder in 1811. Its library contains upwards of 300,000 volumes; and among its auxiliary establishments are botanic gardens, an observatory, an anatomical and an antiquarian museum. In 1873 its professors and teachers numbered 103, and its students 962, the majority in the Faculty of Arts. Among the minor institutions are four gymnasiums, a higher girls' school, a normal school, a school of arts and manufactures, several orphanages, a deaf and dumb institute, and a blind asylum. There are also seventeen hospitals and numerous charitable foundations. The town is the seat of several provincial courts, a chamber of mines, an independent Roman Catholic bishopric, and a Protestant consistory. Its manufactures, which are both varied and extensive, comprise machinery and tools, railway carriages, cast-iron goods, gold and silver work, carpets, woollen cloth, cotton goods, paper, and musical instruments. A very active export trade is carried on; and a number of large fairs for particular kinds of goods are held every year. The population, which was 110,702 in 1849, had increased to 171,926 in 1867, when about 33 per cent. was Roman Catholic, 58 Protestant, and 7 Jewish. In 1871 the total amounted to 207,977.

Breslau (Latin, *Vratislavia*) is first mentioned by Ditmar, the chronicler, in 1000 A.D.; and its foundation seems to be of slightly earlier date. It became the seat of a bishop in 1052, and the capital of an independent duchy in 1163. In 1241 it was reduced to ashes by the Mongolian invaders; but it soon recovered its prosperity, and, its population becoming largely Germanized, it joined the Hanseatic League in 1261. On the death of Henry, the last duke, in 1335, the lordship of Breslau passed to the Bohemian crown; and several of the Bohemian kings bestowed numerous privileges on the city, which began to extend its commerce in all directions,—to Russia and Tartary, Greece and Italy, the Netherlands and Flanders. Under the stimulus of prosperity the citizens soon showed themselves disposed to assert their independence, both against the aristocratic element within their walls, and against their feudal superiors without. From 1482 to 1490 they suffered severely from the oppressive measures of Stein, the minister of their king, Corvinus of Hungary, whom they had preferred to George Podiebrad of Bohemia. After the battle of Mohacz, Breslau passed with the rest of Silesia to the house of Austria, in whose possession it continued till 1741, when it was captured by Frederick II. of Prussia. In 1757 it was retaken by the Austrians under Charles of Lorraine, but in the same year the Prussians again made good their claim by force of arms, and took no fewer than 21,000 men prisoners. The attempt of Laudon in 1760 to surprise the city was a failure. It was forced, however, after a lengthened siege to yield to the French in 1806–7. Their subsequent investment of it in 1813 was interrupted by the peace.

BREST, a strongly fortified seaport town of France, capital of an arrondissement in the department of Finistère, in 48° 22′ N. lat. and 4° 32′ W. long. It is situated to the north of a magnificent land-locked bay, and occupies the slopes of two hills divided by the River Penfeld,—the part of the town on the left bank being regarded as Brest proper, while the part on the right is known as Recouvrance, from the chapel of the Virgin, to whom the shipwrecked sailors used to address their prayers



Roadstead of Brest.

for the recovery of their property. The hill-sides are in some places so steep that the ascent from the lower to the upper town has to be effected by flights of stairs; and the second or third story of one house is often on a level with the ground story of the next. The town proper has three long parallel streets, of which the chief bears the name of Rue de Siam, in honour of the Siamese embassy sent to Louis XIV., and terminates at the remarkable swing-bridge, or *Pont Impérial*, constructed in 1861, which crosses the mouth of the Penfeld. Running along the shore to the south of the town is the Cours d'Ajot, one of the finest promenades of its kind in France, named after the engineer who constructed it. It is planted with trees and

adorned with two marble statues presented by the "Gouvernement Consulaire, Le XIIII°. Germinal, An IX." Brest possesses comparatively few buildings of importance, with the exception of those connected with the great naval establishment. The church of the priory of the Seven Saints, the church of St Louis, the old castle with its seven massive towers (dating in part from the 13th century), the exchange, the town-house, the civil hospital, and the theatre are the chief. The great convict establishment, which formerly held some 3000 prisoners, was vacated in 1860, and is now used as a store-house. The Government dockyard is very extensive, and contains a sail-loft, a slop-shop, a ropery, a foundry and steam-factory, seamen's barracks (known as *La Cayenne*), and three dry-docks partly excavated in the hill-side. The Hôpital de la Marine, built between 1824 and 1835, contains 26 wards, each with 53 beds, and is under the management of a large band of sisters of mercy. Among the minor establishments are a lyceum, a school of navigation, a medico-chirurgical school, an observatory, a botanical garden, a public library of 25,000 volumes, and two others of 18,000 and 10,000. The manufactures are few, and the trade is of small extent considering the excellence of the ports. The former are chiefly leather, wax-cloth, paper, and rope; and the latter deals mainly in grain, beer, brandy, and fish. Napoleon III. did much for the development of the commerce of Brest, though his extensive plans for a new port, on which £600,000 were expended during his reign, have been only partially carried out. It lies at the foot of the Cours d'Ajot, and has thus much greater scope for any necessary development than the old port, which was formed by the mouth of the Penfeld. The roadstead of Brest, which is in some places three miles broad, and has an area of 15 square leagues, is formed by the promontory of Finistère on the N. and that of Kélernn on the S. It breaks up into numerous smaller bays or arms, formed by the embouchures of streams, the most important being the Anse de Kélernn, the Anse de Poulmie, and the mouths of the Châteaulin, the Dolas, the Lauberlach, and the Landerneau. It is defended on every side by batteries and forts, the first system of which was erected in 1680 under the personal superintendence of Vauban. The only entrance, the Goulet, is about a mile wide; but the Mingant or Mingam rock in the middle compels vessels to pass under the batteries of either the one side or the other. In 1851 the population of the town was 36,500; in 1871 it was 66,272.

Nothing definite is known of Brest till about 1040, when it was ceded by the Count of Léon to the first duke of Brittany. In 1372 duke John IV. gave it up to the English on condition that they should restore it when peace was proclaimed. So important did he consider the place that he declared, "He is not duke of Brittany who is not lord of Brest." On the death of Edward III. the castle was made over to the dukes; but when war was once more declared between France and England, an English garrison took possession again, and repelled every effort to dislodge it; nor was the place surrendered till 1397, and then only in consideration of a heavy ransom. In the next century it was again captured by the English, and retaken by the French; and by the marriage of Louis XII. with Anne of Brittany, it passed to the French crown. The advantages of the situation for a seaport town were first recognized by Richelieu, who, in 1631, constructed a harbour with wooden wharves, which soon became a station of the French navy. Colbert changed the wooden wharves for masonry, and otherwise improved the port, and Vauban's fortifications followed in 1680–88. In 1694 an English squadron, under Berkeley, was miserably defeated in attempting a landing; but in 1794, during the revolutionary war, the French fleet, under Villaret de Joyeuse, was as thoroughly beaten in the same place by the English admiral Howe.

BREST-LITOVSK (in Polish Brzesc, and in the chronicles Berestie and Berestoff), a town of Russia, in the government of Grodno, and 131 miles S. from the city of that name, in 52° 5′ N. lat. and 23° 39′ E. long., at the junction of the navigable river Mukhovetz with the Bug. It contains two or three Greek churches, a Roman Catholic church, a Jewish synagogue—which was regarded in the 16th century as the first in Europe, a monastery, a public hospital, a Jewish almshouse, an important provision storehouse, a custom-house, and a wharf. Brest is the seat of an Armenian bishop, who has authority over the Armenians throughout the whole country; and since 1841 the "Alexander" cadette-corps has been stationed in the town. The industries of the place are comparatively unimportant, but it carries on a very extensive and varied trade by means of its rivers and the Royal Canal. The principal articles of the traffic are grain, flax, hemp, wood, birch-tar, and leather. The population numbered 19,343 in 1860, 3394 being Catholics, and 10,320 Jews. In 1867 the total had risen to 22,493.

First mentioned in the beginning of the 11th century, Brest continued to pass from one principality to another till 1392, when it was incorporated with Poland. In 1241 it had been laid waste by Tatars, and was not restored till 1275; its suburbs were burned by the Teutonic knights in 1379, and in the end of the 15th century the whole town met a similar fate at the hands of Mengly-Gherai of the Crimea. In the reign of Sigismund diets were held in Brest; and in 1594 and 1596, it was the meeting-place of two remarkable councils of the bishops of Western Russia. In 1706 the town was captured by the Swedes; in 1793 it was added to the Russian empire; and in 1794 was the scene of Suwaroff's victory over the Polish general Sierakofsky.

BRETAGNE. See Brittany.

BRETSCHNEIDER, Karl Gottlieb, an eminent scholar and theologian, of the more moderate school of German rationalism, was born on the 11th February 1776, at Gersdorf in Saxony. From his autobiography, which was found amongst his papers after his death, and was published by his son in 1851, we obtain a very complete picture, not only of the man himself, but of the times in which he lived, and of the influences by which he was surrounded. His father was pastor of the village of Gersdorf, but was translated to Lichtenstein when Bretschneider was only four years of age. He gives an interesting account of his early childhood and school training, of the impression produced upon him by his father's dignified bearing, and of the agricultural pursuits and piscatorial amusements by which the clerical and pædeutic labours of the latter were diversified. On the death of his father, in 1789, he was sent to Hohenstein to reside with his uncle Tag. It is in keeping with the mental characteristics of the man who afterwards became famous for that cool and deliberate exercise of the reason on theological subjects, which has led many to place him among the extreme school of rationalist divines, to find him at the early age of fourteen, when he was confirmed by the pastor of Hohenstein, criticizing the religious teaching of his instructor, and pointing out that the order in which the various doctrines were taught from the Dresden catechism was not such as could commend itself to his own experience, or the course of moral education which he had undergone. He remarks that he deems the circumstance worthy of mention, "because it was the first time that, having turned his thoughts to the subject of religion, he could not persuade himself of the truth of what he was taught, and that a similar process may be going on in the minds of many a youth in similar circumstances, without the instructor being at all aware of it."

In 1790 Bretschneider was sent to the lyceum of Chemnitz, where the celebrated Heyne had received his classical education. Here he remained four years. The account which he gives of the state of education in this school (which had greatly fallen away from its former reputation), and of the capacity of his instructors, is interesting, and is strikingly illustrative of the growth of that critical faculty which became so prominent a feature

in his character. It was while at Chemnitz that Bretschneider became acquainted with the *Wolfenbüttel Fragments*. The conrector Lessing, a brother of the great Lessing, who was the editor of the *Fragments*, and who was believed for some time to be their real author, was inconsiderate enough to warn his pupils against reading any of his brother's works. The natural result followed. The prohibited books were eagerly sought after, and perused with avidity. Contrary, however, to what might at first have been expected, the persual of the *Fragments* made no impression on the mind of Bretschneider. The independent judgment of the youth is seen in the criticism which he passed upon the book :—"I read the portion," he says, "which treats of the miracles of the Old Testament. But the reading made no impression upon me, for Christianity did not appear to me to rest at all upon the miracles of the Old Testament."

In 1794 Bretschneider entered the university of Leipsic, having resolved to devote himself to the study of theology. His resolution to adopt this profession was purely the result of circumstances. "His father had expressed a wish that he should do so, and all his mother's brothers were clergymen." The lectures which he attended were those of Platner on philosophy, of Keil and Beck and Burscher on various branches of theology, and of Meisner and Kuhnoel on Hebrew. His autobiography contains minute and severe criticisms upon the various professors, in which the defects and mistakes of their teaching are pointed out. One or two of these may be quoted as indicative of the mental tendencies of the writer. Speaking of the lectures on philosophy, and after pointing out the defects of Platner's method, he says,—"Even at this early period, I learned from experience the impossibility for me of adopting any doctrine, except on condition of its standing fully and clearly developed before me,—a peculiarity which has adhered to me during my whole life, and has always preserved me from mysticism and the theology of feeling." Again, in referring to the lectures of Beck on the exegesis of Scripture, the future lexicographer of the New Testament appears in the remark,—"I well remember how burdensome the word πνεῦμα and πνεῦμα ἅγιον became, which he explained now as expressing *sensum christianum*, and now as *fervorem animi*, and then, again, as something else. I felt that these explanations were not correct, and consequently could not accept them." With the lectures of Keil, the successor of the celebrated Morus, Bretschneider appears to have been better satisfied. He adopted his principle of the historical interpretation of Scripture, and entered, as he says, "with the greatest zeal upon the study of the Jewish theology and its *usus loquendi*. In consequence of this, a multitude of arbitrary explanations were set aside, and neither for Teller's dictionary, nor for other modern interpretations, in which new ideas are attached to the words of Scripture, could I acquire the least relish. The efforts to explain away the devil from the Bible, to reduce the passages respecting Christ's pre-existence and higher nature to a moral sense, to make the miracles of the New Testament by exegetical subtleties mere natural events, were odious to me as denials of divine truth."

After spending four years at Leipsic, Bretschneider accepted the office of tutor to the sons of a Saxon nobleman, a post which he retained for some years. During this period his resolution to make the church his profession seems to have been somewhat shaken. His difficulties, however, were removed by reading the observations on assent to creeds in Reinhard's *Christian Ethics*, and also "by the thought that many great and estimable theologians varied widely from the church faith, and that in general society, and in the learned world, the *enlightened* theologians (for the term rationalist was not common then) stood in the highest repute, and were regarded with universal respect. This state of things I supposed would be permanent, and I could not then have believed that only a single generation would pass before the enlightened theologians would be assailed with such violence and bespattered with filth as they now are. Had I been able to foresee this, I should certainly have devoted myself to the study of law."

In 1802 Bretschneider passed with great distinction the examination for *candidatus theologiæ*, and on that occasion attracted the favourable regard of Reinhard, the celebrated court-preacher at Dresden, who became his warm friend and patron during the remainder of his life. In 1804 Bretschneider established himself as *privat-docent* at the university of Wittenberg, where he remained about two years, giving lectures on philosophy and theology. It was during this time that he began his career as an author. The first production of his pen was his *Dogmatische Entwicklung aller in der Dogmatik vorkommenden Begriffe nach den Symbolischen Schriften der evangelisch-lutherischen und reformirten Kirche und den wichtigsten dogmatischen Lehrbüchern ihrer Theologen, nebst der Literatur vorzüglich der neueren über alle Theile der Dogmatik*, which appeared in 1805, and reached a fourth edition in 1841, and which is distinguished for the complete account which it contains of the literature of the subject. This was followed by other works, among which may be named an edition of the book of Ecclesiasticus with a commentary in Latin, which was intended to form part of a larger work upon the Apocryphal books of the Old Testament,—an undertaking that was never carried out. The advance of the French army under Napoleon into Prussia after the battle of Austerlitz determined Bretschneider to leave Wittenberg, which as a fortified town was liable to be exposed to all the horrors of a siege. He accordingly abandoned his university career, and, through the good offices of his friend Reinhard, obtained the pastorate of Schneeberg in Saxony, on the duties of which he entered in March 1807. In 1808 he was promoted to the office of superintendent of the church of Annaberg, which, in addition to the properly clerical duties which belonged to the charge, involved the consideration of many matters belonging to the department of ecclesiastical law, which had to be decided in accordance with the canon law of Saxony. Bretschneider, however, devoted himself energetically to his duties. "The *Corpus Juris Saxonici*," he says, "was almost always on my table, and I soon became perfectly acquainted with its contents." In Annaberg he passed eight years, during which time he twice declined the offer of a professorship of theology, once from Königsberg and once from Berlin. The climate, however, did not agree with him, and in consequence of the demands made upon him by the discharge of his official duties, he was prevented from devoting sufficient time to his theological studies. He, therefore, began to desire a change. With a view to this, he publicly took the degree of doctor of theology in Wittenberg in August 1812. The subject of his thesis was "Capita Theologiæ Judaicæ," as gathered chiefly from the writings of Josephus. It was the last public doctorate of the kind, and cost him 300 thalers (£45), "an expense," he remarks, "which he often regretted, as the title was shortly after made common." It may have been some little consolation to him that the people of Annaberg on his return commemorated his promotion in a number of poems composed for the occasion.

The desired change came at last. In 1816, on the death of Loeffler, general superintendent at Gotha, he was appointed, on the recommendation of Von Ammon, Reinhard's successor at Dresden, to the vacant post, in which he remained until his death in 1848. This was the

great period of his literary activity. By a careful economy of time, he was able to discharge his official duties, and yet to possess sufficient leisure for theological study. Of the various productions of his pen, which appeared during his residence at Gotha, the following are specially worthy of note. In 1820 was published his treatise on the gospel of St John, entitled *Probabilia de Evangelii et Epistolarum Joannis Apostoli indole et origine eruditorum judiciis modeste subjecit K. G. Bretschneider*. The sensation which this work produced was immense. In it he collected together with great fulness, and discussed with marked moderation of tone, the various arguments which seem to prove the non-Johannine authorship of the gospel. As might have been expected, it called forth a host of replies, several of which proceeded from some of the ablest scholars and divines of the day. To the astonishment of every one, Bretschneider announced in the preface to the second edition of his *Dogmatik* in 1822, that he had never believed in the non-authenticity of the gospel, that he had only published his *Probabilia* to draw attention to the subject, and to call forth a more complete defence of its genuineness; an object which he considered had now been fully accomplished. Whatever may have been the effect produced on the mind of Bretschneider himself by the various replies which appeared, they certainly did not remove the doubts of others, for the controversy still appears as far from being definitely settled as it was when the *Probabilia* appeared more than half a century ago. Bretschneider remarks in his autobiography that the publication of this work had the effect of preventing his appointment as successor to Tittmann in Dresden, the minister Von Einsiedel violently opposing the proposal of the city council to call Bretschneider to the office, and denouncing him as the "slanderer of John" (*Der Johannis Schänder*).

The work by which Bretschneider conferred the greatest service upon the science of exegesis was his *Lexicon Manuale Græco-Latinum in libros Novi Testamenti*, which appeared in 1824, and which attained a third edition in 1840. This work is valuable for the use which its author made of the Greek of the Septuagint, of the Old and New Testament Apocrypha, of Josephus, and of the apostolic fathers in illustration of the language of the New Testament.

Bretschneider's dogmatic writings were very numerous, and many of them passed through several editions. The only one which has been translated into English is his *Manual of the Religion and History of the Christian Church*, which appeared in 1857.

The dogmatic position of Bretschneider seems to be intermediate between the extreme school of naturalists, such as Paulus, Röhr, and Wegscheider on the one hand, and that of Strauss and Baur on the other. Recognizing a supernatural element in Scripture, he nevertheless allowed to the full the critical exercise of reason in the interpretation of its dogmas. As a theologian he was deficient in speculative power, and his writings are marked by a certain dryness. His mental strength lay in the possession of a clear, cool judgment, which he never allowed to be influenced by feeling, and in the faculty of untiring industry.

For further information the reader is referred to his autobiography, *Aus Meinen Leben: Selbstbiographie von Karl Gottlieb Bretschneider*, Gotha, 1851, of which a translation, with notes, by Professor George E. Day, appeared in the *Bibliotheca Sacra and American Biblical Repository*, Nos. 36 and 38, 1852, 1853. (F. C.)

BREUGHEL, JAN, a Flemish painter, son of Peeter Breughel, was born at Brussels about the year 1569. He first applied himself to painting flowers and fruits, and afterwards acquired considerable reputation by his landscapes and sea-pieces. After residing long at Cologne he travelled into Italy, where his landscapes, adorned with small figures, were greatly admired. He left a large number of pictures, chiefly landscapes, which are executed with great skill. Rubens made use of Breughel's hand in the landscape part of several of his small pictures,—such as his Vertumnus and Pomona, the Satyr viewing the Sleeping Nymph, and the Terrestrial Paradise, which by some is regarded as the masterpiece of that great artist. Breughel died in 1642.

BREUGHEL, PEETER, a Flemish painter, was the son of a peasant residing in the village of Breughel near Breda. After receiving instruction in painting from Koek, whose daughter he married, he spent some time in France and Italy, and then went to Antwerp, where he was elected into the Academy in 1551. He finally settled at Brussels and died there. The subjects of his pictures are chiefly humorous figures, like those of D. Teniers; and if he wants the delicate touch and silvery clearness of that master, he has abundant spirit and comic power. He is said to have died about the year 1570 at the age of 60; other accounts give 1590 as the date of his death. Several other painters of the name Breughel attained to some distinction.

BREVIARIUM ALARICANUM, a collection of Roman law, compiled by order of Alaric II., king of the Visigoths, with the advice of his bishops and nobles, in the twenty-second year of his reign (506 A.D.) It comprises sixteen books of the Theodosian code; the Novells of Theodosius II., Valentinianus III., Marcianus, Majorianus, and Severus; the Institutes of Gaius; five books of the *Sententiæ Receptæ* of Julius Paulus; thirteen titles of the Gregorian code; two titles of the Hermogenian code; and a fragment of the first book of the *Responsa Papiani*. It is termed a code (codex) in the certificate of Anianus, the king's referendary, but unlike the code of Justinian, from which the writings of jurists were excluded, it comprises both imperial constitutions (*leges*) and juridical treatises (*jura*). From the circumstance that the Breviarium has prefixed to it a royal rescript (*commonitorium*) directing that copies of it, certified under the hand of Anianus, should be received exclusively as law throughout the kingdom of the Visigoths, the compilation of the code has been attributed to Anianus by many writers, and it is frequently designated the Breviary of Anianus (Breviarium Aniani). The code, however, appears to have been known amongst the Visigoths by the title of "Lex Romana," or "Lex Theodosii," and it was not until the 16th century that the title of "Breviarium" was introduced to distinguish it from a recast of the code, which was introduced into Northern Italy in the 9th century for the use of the Romans in Lombardy. This recast of the Visigothic code has been preserved in a MS. known as the Codex Utinensis, which was formerly kept in the archives of the cathedral of Udine, but is now lost; and it was published in the last century for the first time by Canciani in his collection of ancient laws entitled *Barbarorum Leges Antiquæ*. It has been published in the present century by Walter in his *Corpus Juris Germanici*, Berolini, 1824. Another MS. of this Lombard recast of the Visigothic code has lately been discovered by Hanel in the library of St Gall. Neither of these MSS. comprises the whole of the Visigothic code, and it is the opinion of very competent scholars that the Lex Romana of the Lombards did not contain any portion of the Gregorian or Hemogenian code nor the fragment of the *Responsa Papiani*. The chief value of the Visigothic code consists in the fact, that it is the only collection of Roman Law in which the five first books of the Theodosian code and five books of the *Sententiæ Receptæ* of Julius Paulus have been preserved, and until the discovery of a MS. in the chapter library in Verona, which contained the greater part of the Institutes of Gaius, it was the only work in which any portion of the institutional writings of that great jurist

had come down to us. The most complete edition of the Breviarium will be found in the collection of Roman law published under the title of *Jus Civile Ante-Justinianum*, Berolini, 1815.

BREVIARY (Lat. *breviarium*), the book which contains the offices for the canonical hours. The word first occurs in the 11th century, and is said to denote that the book was an abridgment of several separate ones which had previously been in use. The English equivalent for it is *portuary* (from the mediæval Latin *portiforium*), *portesse*, or *portuasse*, the name probably indicating the *portability* of the volumes.

In the earliest times most of the stated public devotions of the faithful grouped themselves round the daily celebration of the eucharistic sacrifice; but by degrees other offices were added, in which the recitation of the Psalter formed the principal part. The rise of monasticism gave a great impulse to the movement, as the monks generally used the whole Psalter every week, and many of them every day. Numerous complications were added by degrees, in the shape of antiphons, responses, &c. Metrical hymns seem to date from St Ambrose in the middle of the 14th century. Select portions of holy Scripture were also read, as well as extracts from works of the Fathers and from lives of the saints.

The canonical hours are eight in number; the night office of matins (divided into three nocturns) and seven day offices,—lauds, prime (at 7 A.M.), terce (at the third hour or 9 A.M.), sext (at the sixth hour, noon), nones (at the ninth hour, 3 P.M.), vespers (at sunset), and compline before retiring to rest.

From this account it will at once be seen that the Breviary services can only be carried out in a monastic community where all other duties give place to worship. Accordingly, the secular clergy of the Latin churches who are obliged to recite them daily are allowed much latitude in the way of grouping services together, and saying them at any hour that may be convenient, which quite destroys the grand theory of the nightly and seven-fold daily offices of devotion. There were three leading types of this service book in the Western churches:—(1), the Mozarabic Breviary, once in use throughout all Spain, but now confined to a single foundation at Toledo; it is remarkable for the number and length of its hymns, and for the majority of its collects being addressed to God the Son; (2), the Ambrosian, now confined to Milan, where it owes its retention to the attachment of the clergy and people to their traditionary rites which they derive from St Ambrose; and (3), the Roman, which (with many minor variations) forms the ground-work of all others except those just mentioned.

Till the Council of Trent every bishop had full power to regulate the Breviary of his own diocese; and this was acted upon almost everywhere. Each monastic community, also, had one of its own. Pope Pius V., however, while sanctioning those which could show at least 200 years of existence, made the Roman obligatory in all other places. But the influence of the court of Rome has gradually gone much beyond this, and has superseded almost all the local "uses." The Roman has thus become nearly universal, with the allowance only of additional offices for saints specially venerated in each particular diocese.

The Roman Breviary has undergone several revisions. The most remarkable of these is that by Cardinal Quignon (1536), which, though not accepted by Rome, formed the model for the still more thorough reform made in 1549 by the Church of England, whose daily morning and evening services are but a condensation and simplification of the Breviary offices. Some parts of the prefaces at the beginning of the English Prayer-Book are free translations of those of Quignon. At the beginning of last century a movement of revision took place in France, and succeeded in modifying about half the Breviaries of that country. Historically, this proceeded from the labours of Launoius and Tillemont, who had shown the falsity of numerous lives of the saints; while theologically, it was produced by the Port Royal school, which led men to dwell more on communion with God as contrasted with the invocation of the saints. This was mainly carried out by the adoption of a rule that all antiphons and responses should be in the exact words of Scripture, which, of course, cut out the whole class of appeals to created beings. The services were at the same time simplified and shortened, and the use of the whole Psalter every week (which had become a mere theory in the Roman Breviary, owing to its frequent supersession by saints' day services) was made a reality. These reformed French Breviaries show a deep knowledge of holy Scripture, and much careful adaptation of different texts; but during the pontificate of the present Pope (Pius IX.) a strong Ultramontane movement has arisen against them. It was inaugurated by the Count de Montalembert, but its literary advocates were chiefly the Abbé Gueranger and M. Veuillot of the *Univers;* and it has succeeded in suppressing them everywhere except at Lyons, where the shadow of St Irenæus still protects the local rites.

The beauty and value of many of the Latin Breviaries were brought to the notice of English churchmen by one of the numbers of the Oxford *Tracts for the Times*, since which time they have been much more studied, both for their own sake and for the light they throw upon the English Prayer-Book.

In a bibliographical point of view some of the early printed Breviaries are among the rarest of literary curiosities, being merely local. The copies were not spread far, and were soon worn out by the daily use made of them. Doubtless many editions have perished without leaving a trace of their existence, while others are known by unique copies. In Scotland the only one which has survived the convulsions of the 16th century is that of Aberdeen, revised by Bishop W. Elphinstone, and printed at Edinburgh by Walter Chepman in 1509. Four copies have been preserved of it, of which one only is complete; but it has been sumptuously reprinted in fac-simile for the Maitland Club by the munificence of the Duke of Buccleuch. It is particularly valuable for the notices of the early history of Scotland which are embedded in the lives of the national saints, and which are considered to be very authentic. For the sake of those who are not familiar with Latin typographical contractions, it would be desirable if a more readable edition were printed, with explanatory notes on the many difficult points which occur in the rubrics.

The Sarum or Salisbury Breviary was much more widely used. The first edition was printed at Venice in 1483, by Raynald de Novimagio in folio; the latest at Paris, 1556, 1557. It may be noticed as a peculiarity that, while modern Breviaries are always printed in four volumes, one for each season of the year, the editions of the Sarum never exceeded two parts.

Further information on this subject will be found in the writers on the services of the Western churches, such as Maskell and Procter. Seager has printed a small portion of the Sarum Breviary with elaborate notes. The hymns have been printed separately, with more or less completeness, by Daniel, Newman, and others; and translations from them form the ground-work of *Hymns Ancient and Modern*, now so extensively used in the Church of England. Foreign writers on this subject may be consulted by those who wish to pursue it further, but they are too numerous to be mentioned here. They will be found enumerated in bibliographical writers like Taccaria. (G. H. F.)

BREWING

BREWING is the art of preparing an exhilarating or intoxicating beverage by means of a process of fermentation. In the modern acceptation of the word, brewing is the operation of preparing beer and ales from any farinaceous grain (chiefly from barley), which is first malted and ground, and its fermentable substance extracted by warm water. This infusion is evaporated by boiling, hops having been added to preserve it. The liquor is then fermented.

The art was known and practised by the Egyptians many hundred years before the Christian era, and afterwards by the Greeks, Romans, and ancient Gauls, from whom it has been handed down to us. All countries, whether civilized or savage, have, in every age, prepared an intoxicating drink of some kind. In the second book of Herodotus, written about 450 B.C., we are told that the Egyptians, being without vines, made wine from corn; but as the grape is mentioned so frequently in Scripture and elsewhere as being most abundant there, and no record exists as to the vine having been destroyed, we must conclude that the historian was only partially acquainted with the productions of that most fertile country. Pliny (*Natural History*, xxii. 82) informs us that the Egyptians made wine from corn, and gives it the name of *zythum* which in the Greek would mean drink from barley; and Hellanicus, telling of the introduction of wine at Plinthium, a city of Egypt, states: "Hence the Egyptians are thought to derive their love and use of this liquor, which they thought so necessary for human bodies, that they invented a wine made from barley." The Greeks, who derived the greater part of their civilization from the Egyptians, obtained from them also the knowledge of artificial fermentation, the art of brewing in fact, and at a very early period. We find it mentioned, for example, in the writings of Archilochus, the Parian poet and satirist, who flourished about 700 B.C., that the Greeks of his day were already acquainted with the art.

Again, we learn from Æschylus (470 B.C.), from Sophocles (420 B.C.), and Theophrastus (300 B.C.), that the Greeks employed barley wine or beer (their *zythos*) in their daily life as well as in their festive meetings. There is, in fact, little doubt that the discovery of beer and its use as an exhilarating drink were nearly as early as those of the grape itself. Xenophon, in his account of the retreat of the ten thousand Greeks, written 400 years B.C., mentions that the inhabitants of Armenia used a fermented drink made from barley. Diodorus Siculus states that the Galatians prepared a fermented beverage from barley, calling it *zythos*, like the Egyptians. By Sophocles and other Greek writers it is styled βρῦτον. Dioscorides mentions two kinds of beer, one he calls ζῦθος and the other κοῦρμι, but he does not describe them sufficiently to enable us to distinguish them. Both, he says, were made from barley, and similar liquors were made in Spain and Britain from wheat. In the time of Tacitus (whose treatise on the manners and customs of the Germans was written in the 1st century of the Christian era), beer was their usual beverage, and from his description, imperfect as it is, there can be no doubt that they understood the method of converting barley into malt. Pliny mentions its use in Spain (*Nat. Hist.*, xxii. 82) under the name of *celia* and *ceria*, and in Gaul under that of *cerevisia* or *cervisia;* and elsewhere (xiv. 29) he says—"The natives who inhabit the west of Europe have a liquor with which they intoxicate themselves, made from corn and water. The manner of making this liquid is somewhat different in Gaul, Spain, and other countries; and it is called by different names, but its nature and properties are everywhere the same. The people of Spain in particular brew this liquor so well that it will keep good a long time. So exquisite is the cunning of mankind in gratifying their vicious appetites, that they have thus invented a method to make water itself produce intoxication."

The *cervisia* of Pliny evidently takes its name from Ceres, the goddess of corn. Plautus calls it *Cerealis liquor*, that is, liquor used at the solemn festival of that goddess. The art of malting and use of beer are supposed to have been introduced into Britain by the Romans. That barley was known to the latter is evident from Virgil, who uses it in the plural form, *hordea*, as we do the word oats; and Pliny tells of the *hordearii gladiatores*, a kind of fencers, whose sustenance was barley. Beer and vinegar were the ordinary beverages of the soldiers under Julius Cæsar. The latter was made very strong, and was drunk diluted with water when on the march. Beer being so suitable to the climate, and so easily made by an agricultural people with plenty of corn, it was gladly welcomed, and soon became the national beverage. Previous to this, the usual drinks of the ancient Britons were water, milk, and mead (an intoxicating drink made from honey). After the expulsion of the Romans from Britain, the Saxons subdued the natives and learned from them the art of brewing.

Dr H. J. Mann tells us that the Kaffre races of South Africa have made for ages, and still make, a fermented drink of beer from the seed of the millet (*Sorghum vulgare*), which is first subjected to a malting process in all essential particulars identical with our own. The seed is first induced to germinate by covering it in a warm place with moistened mats of grass, and the sprouting is then stopped by the application of heat. After simmering for some time in hot water, the malted grain is set aside to ferment in the sun—fragments of a dried succulent plant having been stirred in to play the part of yeast and start the fermentation. The scum which rises to the surface during the fermentation is skimmed away from time to time by ladles made of grass stems spread out and loosely woven together at the bowl. When the fermentation is complete the beer is poured through a mat strainer, shaped and tasselled very much like an inverted night-cap, into the store vessel, which is made of thickly and firmly woven grass. The natives of Nubia, Abyssinia, and other parts of Africa also make an intoxicating drink of great power called bousa, from the flour of the teff (*Poa abyssinica*), and from the durrha or millet (*Sorghum vulgare*), much esteemed by the natives, and perferred by many to palm or date wine, the common intoxicating drink in tropical countries. According to Mungo Park, the natives of Africa also make a beverage from the seed of the spiked or eared soft-grass (*Holcus spicatus*). The Russian drink kvass or quass, a thick, sour beverage, not unlike bousa, is made of barley and rye flour, mixed with water and fermented. Formerly, the spruce-fir, birch, maple, and ash trees were tapped, and their juice used in England,—the first two, indeed, till within the last fifty years. Koumiss, the drink of the Tatar race, is the fermented milk of their mares. The Chinese beverage, sam-shee, is made from rice. This is not only intoxicating, but, like absinthe, peculiarly mischievous in its permanent effects. In South America a favourite drink is pulque, the fermented juice of the American aloe (*Agave americana*). Guarapo is the juice of the sugar-cane, which, when fermented, forms the common drink of the negro

races, who also prepare a drink from rice and honey. Where beer has once been introduced, however, it has generally become the national beverage, and is now in universal use in the northern and temperate parts of Europe and Asia.

Beer used formerly to be made in England from wheat; but this beverage was not so well flavoured as if prepared from barley-malt, nor did it keep long. It was esteemed in Germany and Denmark, and was called by the Germans *Mumme*, and by the Danes *mom*. The German *Weiss-bier* is made from wheat-malt, with a small portion of barley-malt added.

We are informed by William of Malmesbury that, in the reign of Henry II., the English were greatly addicted to drinking. The monasteries were remarkable for the strength and purity of their ales, brewed from malt prepared by the monks with great care and skill. The waters of Burton-on-Trent began to be famous in the 13th century. The secret of their being so especially adapted for brewing was first discovered by some monks, who held land in the adjacent neighbourhood of Wetmore. There is a document still extant, dated 1295, in which it is stated that Matilda, daughter of Nicholas de Shoben, had re-leased to the abbot and convent of Burton-on-Trent certain tenements within and without the town; for which re-lease they granted her, daily for life, two white loaves from the monastery, two gallons of conventual beer, and one penny, besides seven gallons of beer for the men. The abbots of Burton must also have made their own malt, for it was a common covenant in leases of mills belonging to the abbey, that the malt of the lords of the manor, both spiritual and temporal, should be ground free of charge. Mary Queen of Scots, in the midst of her troubles, seems not to have been altogether insensible to the attractions of English beer, for when she was confined in Tutbury Castle, Walsingham her secretary asked, "At what place near Tutbury beer may be provided for her majestie's use?" to which Sir Ralph Sadler, governor of the castle, made reply, "Beer may be had at Burton, three miles off." Plot, in his *Natural History of Staffordshire*, written 200 years ago, refers to the peculiar properties possessed by the Burton waters, from which, he says, "by an art well known in this country good ale is made, in the management of which they have a knack of fining it in three days to that degree that it shall not only be potable, but is clear and palatable as one could desire any drink of this kind to be." In 1630 Burton beer began to be known in London, being sold at "ye Peacocke," in Gray's Inn Lane, and, according to the *Spectator*, was in great demand amongst the visitors at Vauxhall. In 1585 Stow relates that there were 26 brewers in the city of London, the suburbs, and Westminster,—13 being English and 13 foreigners,—who brewed 648,960 barrels of beer, of which they exported 26,400 barrels to Embden, the Low Countries, and Dieppe. In 1643 the first excise was imposed on beer. In William III.'s reign, the brewer sold his nut-brown ale at 16s. per barrel, and his small beer from the same grains for 6s. per barrel.

At the present day the brewing trade has reached vast proportions in Great Britain. It would appear that its extent has now attained the *maximum;* the quantity produced for export is likely to decline, as most of the colonies are beginning to make their own. The pale ale of Tasmania deserves particular notice; the climate being specially favourable to hop-growing and malting, that colony not only produces its home-supply, but carries on an export trade with Australia. According to the report to Messrs Bass by Professor Leone Levi, the number of persons employed in and depending on the British liquor trade is 1,500,000, and the capital invested in it amounts to £117,000,000. There are 5000 maltsters, 34,000 licensed brewers, 6000 dealers in ales, and 139,000 publicans. These pay nearly £8,000,000 a year for permission to make and sell the popular drink. The quantity of beer brewed in 1869 was 25,542,664 barrels, of which 521,272 barrels were exported; whilst in 1874 the exports were 573,957 barrels, of the declared value of £2,508,883. It has been estimated that Barclay & Perkins (successors to Thrale, Johnson's friend) have £1,500,000 sunk in their trade. Bass, the largest brewer in the world, pays license on 1,000,000 barrels, and there are eighteen other brewers who pay duty on 200,000 barrels. From the excise official returns we find the annual consumption per head of the population is

In England, 2 bushels of malt, $\frac{1}{2}$ gallon of spirits.
" Scotland, $\frac{7}{10}$ " " $1\frac{1}{2}$ " "
" Ireland, $\frac{4}{10}$ " " $\frac{8}{10}$ " "

The first essay known to us on the subject of brewing is by Basil Valentine. Boerhaave says of this treatise that it is both accurate and elegant. In 1573 H. Knaust published a work in five volumes at Erfurt, with the quaint title, *On the Divine Noble Gift, the Philosophical, highly Dear, and Wondrous Art to Brew Beer.* In the year 1585 Thaddeus Hagecius ab Hayck (a Bohemian), published a treatise entitled *De Cerevisia, ejusque conficiendi ratione, natura, viribus, et facultatibus.* This small work of fifty pages gives a very clear and accurate description of the process of brewing. To Mr Combrune, a London brewer in the earlier part of the 18th century, we are indebted for the proofs he gave of the value of the thermometer in brewing. In other respects his work entitled *The Theory and Practice of Brewing*, is of no particular value at the present day, though it was very useful at the time in advancing the art, and ran through several editions. Previous to his time brewers had looked upon the thermometer as a scientific toy, and "rule of thumb" was the order of the day. In the year 1784 Mr Richardson of Hull brought out his *Theoretic Hints on Brewing Malt Liquor*, and *Statistical Estimates of the Materials of Brewing, showing the use of the Saccharometer.* These works would be beneficial but for the absurd mystery with which the author invests the whole subject. It was he who first brought publicly to the notice of brewers the value of the saccharometer, an improvement of his own on the hydrometer, or water guage, invented by Martin, the Fleet Street mathematician. Mr Baverstock purchased one of these in 1768, and in 1770 received a certificate of the value of his instrument from Mr Thrale, the celebrated brewer in Southwark, who had tested it. It was not, however, till 1785 that Mr Baverstock published his *Hydrometrical Observations and Experiments in the Breweries;* so that Mr Richardson has the merit of bringing his improved hydrometer, which he christened saccharometer, first to the notice of the trade. By this instrument the brewer is enabled to ascertain the amount of saccharine or fermentable matter in the wort, and thus to take advantage of a particularly good sample of malt, or to compensate for a bad one, so as to procure an uniform strength. Malt varies in quality according to season, the skill of the maltster, and other circumstances. Samples of barley raised from the same seed, and grown in adjoining fields, will produce malt widely different, although this is not discovered till it has been in the mash tun. The quantity of malt which suffices for a particular "length" to-day may fall far short of affording the same quantity of ale to morrow, and *vice versa.* In either case the saccharometer is essential, as it enables the brewer to make his ales one standard strength. The instrument is also of great service in regulating the fermentations.

Mr Richardson's saccharometer was constructed on the principle that 36 gallons (one barrel) of water weighs 360 lb, and if that quantity of water were converted into wort

and the scar or eye, through which the seed is nourished during the process. The hard white part is termed, botanically, albumen. This is the cotyledon, and forms the chief part of the seed, supplying the germ with food during the first few days of its existence. With the germ, which begins to exist within an hour of being put in steep, springs also into existence the principle termed diastase. This name (from διίστημι, to separate) was given it by MM. Payen and Persoz, who made numerous experiments with it.

According to Muspratt, diastase may be obtained by making a paste of malted grain at a temperature of 76°, allowing it to stand for a few minutes, and then pressing out the liquor, which is afterwards filtered and heated in a water bath at 170°. At this temperature a portion of the foreign nitrogenous matter coagulates, which is afterwards separated by filtration. The clear filtrate, which contains tolerably pure diastase, is evaporated at a low temperature to dryness. Diastase is not only soluble itself, but has the power of dissolving starch, and converting it into soluble gum, to which is given the name dextrin, and finally into grape sugar, so called because, on analysis, it closely resembles the sugar which naturally exists in the grape. So powerful is diastase, that one part will convert 2000 parts of starch into grape-sugar. This operation will be noticed below under the head of mashing. It is on account of this wonderful power of diastase to convert starch into saccharine matter, that distillers use one part of malt in mashing to five parts of raw grain. The next part of the seed that comes under notice is the corcule, which is the embryo of the future plant. This germ, feeding on the sugar formed from the starch of the cotyledon by the action of diastase, grows upwards and downwards,—the upward growth being the plumule or "acrospire," the downward the radicle or future root. Acetic acid (vinegar), which does not exist in raw grain in a free state, is now also formed; this assists the diastase in its action.

The maltster's object is to obtain as much saccharine matter as possible, with the smallest loss of substance, by converting the starch of the barley into sugar, and thus preparing it for the brewery, where it is changed by fermentation into alcohol. Chemically, starch and sugar are composed of the same elements, carbon, oxygen, and hydrogen; but their atoms are differently arranged,—the mean results of the analyses of Berzelius, Gay-Lussac, and Thenard, giving $\frac{17}{100}$ths of a grain of carbon more in starch than in sugar, whilst sugar contains $\frac{25}{100}$ths of a grain more of oxygen and $\frac{8}{100}$ths less of hydrogen than starch.

The duty on malt forms an important item in the revenue, and stringent laws have been made to enable the excise to levy the duty, and prevent the maltster from defrauding. It may be remarked, however, that although those rules were relaxed or abolished, the process of manufacture would be carried on as it is now. The duty was first raised in the reign of Charles I. on the following scale:—English malt, 4s. 4d.; Scotch barley-malt, 3s. 8½d.; Scotch bigg-malt, 3s. per bushel, but 2s. of this was a war-tax, and the whole was soon repealed. In 1697 a tax was again imposed (to enable William III. to carry on war with France) of 6¾d. per bushel. The rate has been frequently changed, and has ranged between 7d. and 4s. 5¾d. in England, and 7d. and 3s. 9½d. in Scotland. For this and much other information we are indebted to a useful little work on malting published by W. R. Loftus. The present rate of duty on malt made from barley is 2s. 7d. per bushel, and 5 per cent. additional, making in all 2s. 8$\frac{11}{20}$d.; and on malt from bere or bigg, when made for consumption in Scotland or Ireland, 2s., and 5 per cent. additional; when the latter is imported into England the higher duty is charged. The 5 per cent. additional was imposed in 1840 on all exciseable articles, except spirits.

Malting consists of four processes,—steeping, couching, flooring, and kiln-drying.

Steeping is performed in a large cistern of stone, or more usually brick, covered with cement, into which the barley (properly screened, to remove the small useless grains) is shot from the store-chamber above. It is then levelled and covered with water to the depth of 5 or 6 inches, all floating kernels and refuse being skimmed off. This process is necessary for the germination of the seed not only in a chemical but also in a mechanical point of view. The seed is so hard and compact, and the husk so firmly bound to the kernel, that it would be impossible for the tender germ to make its way through it; the steeping imparts vitality to the germ, and also assists it in making its way through the husk. The grain now swells about one-fifth in bulk and one-half in weight from the moisture absorbed; or more precisely, 100 ℔ of barley would weigh, after steeping, 147 ℔, and 100 bushels measure would increase to 122. By law it has to be kept at least forty hours under water, and fifty if the grain is to be sprinkled before the twelfth day. This time must depend on the kind of barley used, the soil on which it was grown, the heat of the weather, and the hardness or softness of the water in which it is steeped. More time is required in cold than in hot weather. Scotch barley requires more time, but bigg less. Fifty hours steeping will generally suffice, but sometimes seventy is necessary. The rule is—if a barleycorn, held lengthwise between the finger and thumb, breaks down into a pulpy, mealy state, the process is complete; whereas, if the farina exudes in the form of a milky paste, it is over-steeped. In warm weather the steep-water acquires an odour from matter dissolved out of the barley skin; and, in consequence of a slight fermentation caused by the organic matter in the water acting on the decayed grain, the water becomes acescent or putrid. The steep-water should then be changed. This the maltster is allowed to do once during each wetting, upon giving due notice to the Excise. Whilst the barley is in steep it is guaged by the excise officers, to prevent fraud, and to calculate the duty to be paid. Wide planks are placed across the cistern to enable them to take the "dip,"—sufficient light, and headroom of at least 48 inches, being provided. Numerous experiments show that 81½ bushels of good dry barley will, after forty-eight hours steep, swell to exactly 100 bushels. An allowance is therefore made of 18½ per cent. on the grain found in the

cistern or couch frame, but the duty is charged on the greatest amount found, whether in the couch or on the floor or kiln. When the operation of steeping is complete the water is drained off in about half an hour by means of a gutter laid below the level of the cistern from end to end, with a proper fall, and covered with perforated iron plates. The perforated plates being movable, the gutter is easily cleaned and the plates replaced. The law requires that every cistern shall be permanently constructed with the sides and ends straight, and at right angles to each other, for facility of measurement; the depth must not exceed 40 inches in any part; the bottom must be even, with a fall of not more than half an inch per foot for drainage. No cistern can be used under a penalty of £100 until a certificate in writing from the supervisor has been obtained, stating that he has surveyed the utensil, and that it is constructed according to the requirements of law.

Couching.—The couch-frame is formed like the cistern, with the exception that the fourth side may be made of movable planks at least 2 inches in thickness. Before the year 1827 it was lawful to construct the couch-frame entirely of movable boards; and couches made before that date may still be used by obtaining permission from the Board of Inland Revenue. Into this frame the grain is now thrown with wooden shovels. It must not be compressed in any way, under heavy penalties, and must not exceed 30 inches in depth. If the excise officer has any suspicion that the grain has been trodden down, he may order it to be thrown back into the cistern and levelled. The officer will then gauge it again. If he finds that the quantity has increased more than 5 or 6 per cent. according to the length of time the grain has been emptied from the cistern, any such increase over and above the 5 or 6 per cent. will be deemed conclusive evidence that the grain has been trodden or forced together. A penalty of £100 is then incurred; and a like sum for maltsters or their men refusing to return the grain to the cistern. After twenty hours the maltster is at liberty to move the grain on to the floors; but, in cold weather, when sufficient heat to forward germination has not generated, it is left two days, and even longer; but if left too long, the grain becomes sour. After sufficient time has elapsed, in order to prevent the heat rising too rapidly, and to equalize it through the whole body of grain, it is thrown forward on to the floors.

Flooring.—Here the grain must be kept level, with the edges straight to make it easy for the officers to gauge, which is done several times to prevent the introduction of uncharged grain. This operation of gauging requires great care, as, in large houses, a mistake of the tenth of an inch would make a difference of between 20 and 30 bushels to the maltster. On the floors an allowance of one-half is made for the rootlets; this is generally quite sufficient. Each steeping is called a "floor" or piece, and must be laid in succession according to age, the most recent next the couch, and the oldest next the kiln. Maltsters may have six floors, including grain in the couch and on the kiln, in operation at one time. Germination now progresses; the plumule, or stem begins to grow under the husk from the same end as the root, but instead of piercing the husk, turns round and proceeds under it to the other end of the grain. This would develop into the green leaf were its progress not stopped. Maltsters vary as to the length it is advisable to let the acrospire attain; some like it not much more than half up the back of the grain, others like it $\frac{3}{4}$ths or even $\frac{7}{8}$ths of its length, because it is practically found that a friability of the starchy matter takes place *pari passu* with the length of the plumule. Unless the floors are worked with great skill and regularity, however, some are apt to protrude when carried to the latter extent. This shows an exhausted condition within. Maltsters who sell by *weight* work the acrospire no higher than is absolutely necessary; the higher it is worked the less starch and the more sugar is produced, and a corresponding loss in weight ensues. The maltster who sells by *measure*, however, likes to have the acrospire as high as he can, to increase the bulk of his malt. The writer's experience is that ales fine better, and keep better, when brewed from malt well worked up. In large mash tuns, where the heat can be maintained, it is not of so much importance; but in small tuns, where less than twenty quarters are mashed, if the "spire" is up $\frac{7}{8}$ths of the grain, so much the better, so long as it is uniform. The temperature on the floor rises to between 50° and 60°; the fibrils of the radicle, the "chick," as it is technically called, shoot from the tip of every corn. The middle of the floor being the warmest starts soonest; so, after a few hours, the grain is turned or stirred, so as to bring all to a similar state of forwardness. At this point comes the critical test of the maltster's skill; no fixed rules can be laid down; he must be guided by experience and circumstances. He has to consider the quality and growth of the barley,—whether it came off light or heavy soil,—the kind of malt intended to be made,—the temperature and peculiarities of his particular malting. His principal object is to get the grain to work, and to work regularly, to accomplish which, and to check the too rapid growth of the rootlets, the grain must be turned several times daily, the interior being always brought to the surface by the shovels of the workmen. The grain is spread more thinly each time, the depth of it, originally 14 or 15 inches, being thus gradually lessened to 3 or 4. This brings it to the middle of the process; it is then thickened as gradually as it was diminished until it is thrown on the kiln. The grain now emits an agreeable odour, something like apples; and if the hand be thrust into the corn it is found wet enough to damp it; this is called sweating. The "chick" develops into several short bushy rootlets. As the acrospire grows the constituents undergo a great change; the gluten and mucilage almost disappear; the grain becomes white, mealy, and sweet; carbonic acid is produced; air is absorbed, almost as by animals in breathing; and, consequently, air is necessary to the germination of the grain. It loses during this part of the process from $1\frac{1}{2}$ to 3 per cent. in weight.

There can be no doubt that it is of importance to the maltster that the law allows him to sprinkle water over the "pieces" on the floor; this may be done at the expiration of ninety hours after removal from the steep, provided such grain has been kept under water fifty hours. Sprinkling is generally commenced on the fifth or sixth day, notice having been given to the Excise twenty-four hours before. If in steep less than fifty hours it may not be sprinkled till the expiration of twelve days. Sprinkling is used most by maltsters who sell by measure, and therefore want to increase the bulk of their malt; but there are seasons when it would be difficult to make good malt unless moisture were thus supplied, to make up the water lost during sweating. Too much light is detrimental, as appears from the fact that grain under the influence of uninterrupted light is inferior, unless the sky-light be covered with a coating of blue, which admits the actinic rays, and excludes the calorific and light rays, which hinder germination. Shutters on the sliding principle are the best for regulating both light and heat. Great care has to be taken not to damage the grain by turning, especially when it is spread thin. To obviate the necessity of turning as much as possible an instrument like a narrow shovel, called a plough, is used, which brings the grains underneath to the surface, and into contact with the cold air, so keeping the germination

regular. Grain is required by law to be kept at least 168 hours on the floors, but maltsters may keep it there as much longer as they like. Barley throws out five rootlets, the middle one being the strongest; and if the young floor has been neglected, this will shoot out three times the length of the others and turn up at the end like an awl. When the grain has germinated sufficiently, its growth is arrested by placing it on the kiln, the object being to drive off superfluous moisture and insure the keeping qualities of the malt.

Kiln-drying.—The kiln is a chamber of which the floor should be made of woven-wire or sheet-iron, or of perforated tiles. The perforations are necessary to give admission to the hot air, and also to allow the detached rootlets to fall through. The kiln should have a sufficient area to allow the whole of one steeping to be dried at once, at a depth of 8 or 10 inches; by which means the malt is more regular than when dried in two or three lots, as the portion left on the floor will grow, notwithstanding the maltster's efforts to prevent it. The opening at the top of the kiln is covered with a cowl or cupola, which answers the double purpose of excluding rain and allowing the escape of the steam. The furnaces are placed under the floor, nearly in the central line, and the hot air passing through the perforations dries the malt, while the steam is carried off through the vent in the roof. An iron or stone plate, 4 or 5 feet square, called the "disperser," is placed over each fire to disperse the heat and prevent the malt immediately above from taking fire. The heat at first should not exceed 90°; if higher it produces a hardening or vitrifaction of the starchy matter or dextrin, and also heightens the colour of the malt; whereas, if the malt be freed from moisture at a low temperature it may afterwards be exposed to a high heat without gaining colour. The moisture being disposed of, the heat may be gradually raised to from 125° to 135° for India pale ale malt, and to 170° or 180° for ordinary pale malt,—the difference in the kinds of malt being the amount of heat to which they are subjected on the kiln. During the process the fires should never be allowed to go out, as the smell of a green fire imparts an unpleasant flavour. During the last few hours in particular there should be a bright, clear fire for finishing off the malt, otherwise the beer will not get bright. It will thus be seen that the process of kiln-drying is very important. Dr Ure's remarks on it are pregnant with meaning. He says, "The operation of kiln-drying is not confined to the mere expulsion of the moisture from the germinated seeds, but it serves to convert into sugar a portion of the starch which remains unchanged, and that in a two-fold way. This is, first, by the action of the gluten upon the fecula at an elevated temperature, as also by the species of roasting which the starch undergoes, and which renders it of a gummy nature. If we dry one portion of the malt in a naturally dry atmosphere, and another on a moderately warm kiln, the former will yield less saccharine matter than the latter. Moreover, the kiln-dried malt has a peculiar agreeable and faintly burnt taste,—probably from a small portion of the empyreumatic oil formed in the husk, which not only imparts its flavour to the beer, but also contributes to its preservation." Kiln-drying takes from one to four days, according to the depth of malt and amount of heat used. The fire being kept always burning, great care is needed to prevent its breaking out in the night; it is therefore made up the last thing and then "banked up," that is, covered with a quantity of the ashes which fall through the bars. For ordinary pale malt, about three hours before it is thrown off the kiln the heat is raised from 150° to 180°, and during this process it requires turning two or three times, and is thrown off the kiln in a hot state. The rootlets are readily detached from the malt by the turning on the kiln, and the treading of the men in their list slippers; they are finally separated by screening, and are the best criterion of the colour of the malt, showing at once the amount of heat used. These malt "combs" or "cummings," as they are called, are valuable food for cattle in winter; and the fine ones which fall through the kiln-floor on the disperser, mixed with the dust from the fire, are said to be almost equal to Peruvian guano as a top dressing for turnips.

Malt continues to swell, by absorbing moisture from the atmosphere, for nearly three months, the time varying according to the dampness of the air. Malt in store is said to be mellowing. The increase by measure of malt over dry barley, called the "outcast," is from 3 to 8 per cent.; in bigg the increase scarcely amounts to 1 per cent. During the process of malting barley loses one-fifth of its weight; in other words, 100 ℔ of barley converted into pale malt weighs on an average 80 ℔: but as barley when kiln-dried loses 12 per cent. of moisture, the actual loss is reckoned at only 8 per cent. The late Professor Thomson thus accounted for it:—

Soluble matter carried off by steep-water	1·5
Carbonic acid formed and given off during germination	3·0
Roots	3·0
Waste (bruised and lost grains)	0·5
	8·0

Dr R. D. Thomson, who made various experiments on malt for the purpose of ascertaining its feeding and fattening properties, states the loss sustained to be

Water	6·00
Saline matter	0·48
Organic „	12·52
	19·00

Bigg sustains a greater loss than barley, amounting to 7 per cent. more. The great similarity which chemical analysis shows to exist between barley and malt, proves that malting is only the beginning of the process by which saccharine matter in solution is obtained. A glance at Stein's analysis of the two will show this:—

There are three kinds of kiln-dried malt—pale, amber, and brown, and one of roasted, called black or patent malt. We have already seen how pale East India malt is made; also that the ordinary pale malt is dried off at a higher temperature by 30° or 40°.

Amber malt, when ground, is of a rich amber colour, hence its name. This is dried off at a heat of 180°. The fuel used during drying is different. For pale malt, coke or anthracite coal is used, but the colour and flavour of amber malt are produced by burning oak or other hard-wood faggots,—the flavour being caused by the pyroligneous acid thrown off during burning. High-coloured malts have advantages over pale; more dextrin is produced and more albuminous matter is rendered insoluble; it is, therefore, easier to brew good beer from them.

Brown or porter malt is dried in yet another way. The floors of malt-kilns used for drying it must be made of thin sheet-iron or stout wire, as the heat must be raised in a few minutes from 100° to a heat nearly approaching combustion, and lowered as rapidly. The process requires great attention, or the malt would take fire. The grain is spread thin, not exceeding 1½ inches in depth; and the whole process is completed in less than two hours. The fuel used consists of faggots of beech, elm, or oak; at first the fire is kept down by being sprinkled with water, but the last half-hour it is allowed to increase, and an intense heat is obtained. This kind of malt weighs about 32 ℔ per bushel. It is sometimes called "blown malt," from its distended appearance. By this process the gum, sugar, and starch are converted into a kind of caramel, which gives the flavour so much prized in porter. It makes the malt, however, deficient in extractive matter, to the extent of from 20 to 30 per cent.

Patent malt, which is the legal colouring-matter in porter, is made and charged with duty in the same way as other malt, and then removed to the roasting premises, where it is treated like coffee, being roasted over a fire in cylinders of perforated iron. The law requires that 95 per cent. of this malt shall have the "spire" extend to one-half the length of the grain in order to prevent the introduction of raw grain. It is generally made from injured or inferior malt, as the high temperature in drying quite restores the appearance. There is, of course, no saccharine extract from it, that having been converted into caramel or burnt-sugar; it is only wanted to supply colour and flavour. Good malt of this kind should have each grain distinct, of its own original size and shape, not adhering to each other; and when it is bitten the inside should be of a rich chocolate colour.

Pale malt differs in appearance from barley; the grains are plump and generally free from wrinkles, and paler than barley. Instead of the tightly-closed end, the opening through which the rootlets have passed is visible at the base of each grain; when broken the starch should be loose, friable, and cretaceous, and should leave a white mark as of chalk when drawn along a black surface. It should be crisp to the teeth, and have a sweet and empyreumatic flavour, free from the least mould or mustiness of smell or taste. Malt should weigh from 39 ℔ to 43 ℔ per bushel. There should be no vitrified appearance when broken; that would be due to an excess of heat at the beginning of the drying process, or to the barley having been grown in too rich a soil, or to mixed seed being used which did not work regularly. A good test is to take 100 seeds and throw them into water, stirring them well up; good malt, being specifically lighter than water, should float on the surface; if more than 5 per cent. sink it is bad malt. Another test is to take 100 grains of malt and carefully examine the regularity of their acrospire, which should extend ⅔ths of the length of the grain for large and ⅞ths for small brewers. If more than 5 per cent. have projected it shows a waste of material, whereas if more than 5 per cent. have the acrospire less than half way up, it is a sign of insufficient germination.

Dr Ure's analysis goes to show the amount of solid extract obtainable by the brewer. He takes 100 grains of malt by weight, which are powdered and dried half-an-hour by the heat from boiling water; they are then weighed, and the loss shows the quantity of moisture in the malt. This powder is then mixed with cold water, and the vessel containing it is heated in the steam-bath half an hour, the contents being occasionally stirred. The husk and insoluble matters are then drained off, washed with boiled water, and then dried and weighed,—their weight giving the insoluble matter in the malt, and the residue the soluble extract available to the brewer. Dr Ure found in several experiments the average in 100 parts by weight, to be—

Moisture	6·5
Insoluble matter	26·7
Soluble extract	66·8
	100·0

According to this, if we assume that a quarter of malt weighs 324 ℔, the total soluble extract will be 216·4 ℔ avoirdupois; but as the gum and sugar in assuming the fluid form combine with the elements of water, if the extract were dried it would weigh 23 ℔; and being reduced to the basis of the barrel of 36 gallons would become, in the language of brewers, 87 ℔ extract per barrel, which means that, if the wort from a quarter of malt were evaporated down to the bulk of a barrel of 36 gallons, it would weigh 87 ℔ more than a barrel of pure water. Practice shows these experiments to be correct, the extract per quarter varying, according to the sample of malt, from 80 ℔ to 90 ℔.

Malt is made duty-free for distillery purposes and exportation; in both cases the maltster has to enter into a bond with two sureties for £1000 that the malt goes to its declared destination. It may also be made free of duty for cattle feeding, an Act giving great facilities being passed in 1864; it was, however, found to be useless, except in small quantities, as a condiment, and the practice of giving it is entirely discontinued. In 1870 there was not a single bushel made, as there was no demand for it. In the case of malt damaged by fire or water, an allowance equal to the whole of the duty, if totally destroyed, or part if the damaged malt be sold on salvage, is granted by 7 and 8 Geo. IV. c. 52, § 76. The duty on malt is payable at the end of every six weeks, but upon entering into a bond with sureties for payment, a maltster is allowed six weeks' credit. Also by 26 Vict. c. 6, § 1, he may defer payment of half the duty on malt made between 1st January and 1st April, and the whole of the duty on malt made between the latter date and 16th May, for three months, on giving notice of his intention to the proper collector before 1st April, paying interest at the rate of 3½ per cent. per annum for the accommodation, and giving bond for security.

By 7 and 8 Geo. IV. c. 52, § 46, it is provided that, if any workman, maliciously or otherwise, commits an act by which his employers are liable to a penalty, he shall be imprisoned with hard labour for not less than three or more than twelve months. The master is liable for these

penalties incurred by the workman unless he prosecute his servant within a month of the offence, and show the Commissioners a certificate of such conviction. Some maltsters have a notice put up in their maltings to the effect that their men will be prosecuted if they commit the offences mentioned in the Act.

In America there are no internal taxes on materials used in brewing as such, but there is an import duty on hops and barley,—five cents per ℔ on the former, and 15 cents on the latter per bushel. The barley mostly used comes from Canada, the import duty being equal to about 1s. 4d. on an American barrel of beer. The duty is levied in the form of a stamp-tax on the beer fermented, completed, and in barrel, at the rate of $1 per barrel of 31 gallons, and $2 per barrel of not less than 63 gallons. No restrictions are imposed as to the materials of which it shall be made.

In Bavaria the duty is raised on malt, but not assessed till the malt is brought to the mill to be crushed. It is made without licence or permission, and may be sold without restriction; but traffic in ground malt is strictly forbidden. The case is the same whether the malt is used by brewers or distillers. The consumption of beer and spirits is untaxed, except through the impost on malt. The means adopted for preventing fraud consist exclusively in the control exercised in the public mills by the Government inspectors. Private mills for crushing malt are only allowed when the proprietors have their mills furnished with the regulation self-acting measuring apparatus, together with the Government automatical counter. This apparatus is sealed officially, and thus it is impossible for an ounce of malt to be crushed which has not first been measured and checked. Besides these means for preventing fraud, there exists a regulation that no malt, whether tax-free or not, may be brought to any mill, or be found there, for which a certificate (polette) has not been given specifying the date, the quality, and the mill.

Americans are now making beer largely from maize meal and maize malt. The experience the writer has had of the use of the latter leads him to doubt its economy; the extract is small, and the fine flavour of the ale impaired. However, a small quantity can be used with advantage where the fermentations are sluggish or inactive,—maize being the most powerful stimulant of this process that we possess. Barley has always been considered, and with good reason, a better, and in favourable seasons a cheaper, grain than any other for malting. The reasons for this are, first, that whilst the husk permits the steep-water to pass through to the starch it effectually precludes the escape of the starch; secondly, the acrospire grows under the husk in barley, and so is protected from injury during malting, whereas in wheat, maize, &c., the acrospire forces its way out with and at the same end as the rootlets, and therefore runs the risk of being damaged by turning on the floors; these damaged grains become mouldy, and mould being propagated by means of spores, one mouldy grain may send out thousands of these spores among the good grain, and infect the previously healthy ones; and thirdly, barley contains a large ready-made proportion of grape-sugar and starch. It is, therefore, only in bad barley seasons that there will be much demand for malt made from other grain. The average price of barley from 1872 to 1875 has been 43s., and in 1874 the average was as high as 49s. This high price, which means a material increase in the cost of manufacture, has naturally made a great inquiry for a cheaper sugar-forming product; and there is no doubt that if the duty on malt were either taken off or laid on the manufactured article, beer, large quantities of other grain dried on a kiln at from 230° to 240° would be used in bad barley seasons. In Germany the grain is steeped before kiln-drying for three or four hours, to remove from the husk the unpleasant flavour it sometimes imparts to ales; the materials used to a considerable extent there are wheat, oats, rice, maize, and even potato starch. Beer made from rice is of a very clear pale colour, of an extremely pleasant, mild taste, foaming strongly, and yet retaining its carbonic acid. Dr Graham, in his instructive lectures on the chemistry of brewing, at the Society of Arts in 1874, explained how raw grain might be used to obtain a beer either alcoholic in its nature, as brewed in England, or dextrinous, like the Bavarian beer. Mr John Prior, of the firm of Truman and Hanbury, in his examination before a committee of the House of Commons, says, "If the malt Acts were not in the way, numerous substitutes for malt might be employed," and that, amongst these, mangel-wurzel might be used to any extent; and he goes on to say, "I have tasted as good beer brewed from that alone as any home-brewed beer I have ever tasted in my life."

The only substitute for malt allowed in Great Britain is sugar. Of this, in its different forms, there was used in the year ending September 30, 1874—

		Cwts.
In England	London	283,736
	Provinces	422,136
		705,872
In Scotland		7,323
In Ireland		54,825
		768,020

being an increase over 1873 of 204,528 cwt. Sugar may be used in brewing to the extent of one-third,—two cwt. being equal to a quarter of malt; the duty is 11s. 6d. per cwt. It is either boiled with the wort, or dissolved in the underback. Ordinary cane-sugar contains a large amount of dangerous putrefying albuminous matter. It may also be said to cause two distinct fermentations, having to be converted, by the action of the ferment, into glucose before it is broken up into alcohol; it is, therefore, only good for ales of quick consumption. For store ales it is as well to destroy one of these fermentations, and at the same time convert the cane into grape-sugar or glucose. This is done by treating it with dilute sulphuric acid, the acid being afterwards got rid of by means of chalk or lime, which combines with and carries it down. This is effected very rapidly if the temperature be increased by pressure to 250° or 300°, 1 ℔ of acid mixed with 600 ℔ of water converting 100 ℔ of starch or cane-sugar into glucose in three hours. This action of acids upon cane-sugar has formed the subject of a patent (Garton's), which is being worked on a large scale at Southampton, and the product is sold under the name of saccharine; it has found great favour with brewers, as it gives a rounder flavour, and more permanent character, to the beers than when brewed from malt alone, and at the same time masks the acidity where any exists, better than starch or cane-sugar. Saccharine has been carefully analysed, and the analysis shows the whole of the raw sugar to have been converted into glucose with a certain percentage of water. The best mode of distinguishing grape from cane-sugar is by adding to the solution to be tested, in a flask, a few drops of an alkaline solution of tartrate of copper, and then gently boiling it. If any grape-sugar is present a bright red metallic-looking precipitate of suboxide of copper is shortly thrown down; if no grape-sugar is present the solution remains clear, with a slight blue tinge, from the addition of the copper solution.

It does not appear that the best judge can, from the taste alone, distinguish between a beer made from malt and one brewed from a mixture of malt and sugar. This is not surprising, when it is borne in mind that brewing from malt consists in subjecting the malt to those condi-

tions which are most favourable to the conversion of the *maximum* quantity of the starch it contains into grape-sugar, by the action of the diastase produced in the grain by the process of malting.

Hops are the catkins or flowers of the *Humulus Lupulus*, a diœcious plant belonging to the natural order *Urticaceæ*, or the nettle family, and the Linnæan *Diœcia pentandria*. It is the female flowers (which grow on different plants from the male flowers) that yield the hop known to commerce. The plant is mentioned by Pliny under the name of *lupus salictarius* (*N. H.*, xxi. 50). It was cultivated in the 9th century, for we find that in 822 the millers of Corbey were freed by the abbot from all labours relating to hops; and hop-gardens are mentioned by Ludovicus Germanicus, a few years later. Hops were introduced into England from Flanders about the time of Henry IV. There is a curious edict of Henry VIII., forbidding the mixture of either hops or sulphur with beer; but little attention seems to have been paid to it, for in 1552 hop-plantations were formed. In 1649 the city of London petitioned Parliament against "hoppes" being used, urging that "this wicked weed would spoil the drink, and endanger the lives of the people." It came into common use in Queen Elizabeth's reign.

The hop-clusters are ovoid cones, consisting of scales which are the enlarged persistent bracts enclosing the fruit. They are covered with a tenacious yellow, waxy substance, like powder, called lupulin, and technically "condition." Under the microscope this is seen to consist of minute semi-transparent granules, round in shape; it is the most valuable part of the hop, containing most of its active properties. The amount of powder compared with the total weight of the hop varies from 10 to 15 or even 20 per cent. Amongst the leaves and powder of the hop, we find essential oils, resin with associated bitter principles, and tannin. When distilled with water, the powder gives 2 per cent. of its weight in essential oils (there is none in the leaves); one of these distils at 212° Fahr., but the other requires a much higher temperature for its volatilization. Other products are formed from the lupulin—among them valerianic acid, which is the disagreeable characteristic of old hops. The essential oils not only give the aroma, but are of importance, as through their combination the resins and bitter substances become soluble in water. The resin constitutes 50 per cent. of the powder, and is soluble in alcohol. The importance of tannin consists in its power to precipitate albuminous matter; of tannin there is only about 2 per cent. It has been suggested to increase this by using the tannic acid of commerce as a partial substitute for hops; and experiments have been made in Dresden by Dr Fleck for this purpose. This must, however, be used with caution, as an excess of it would be prejudicial to a successful clarification of the beer.

The most delicate hops are Goldings, grown in East Kent,—Farnham and Worcester districts being next best, while good, strong, serviceable hops are grown in the Weald of Kent, Sussex, &c. Large quantities are imported from Germany, Belgium, America, &c., the best being Bohemian, grown near Saaz, which are very excellent in delicacy of flavour and aroma; Bavarians grown in the district round Spalt are valuable for their cleansing and beer-keeping qualities.

The acreage under hops in England is 65,000,—40,000 being in Kent. This is an increase of more than 15,000 acres since the commutation of the duty in 1862. In that year the duty was taken off hops, and a charge made on brewers of 1s. per quarter, being at the rate of 3d. per barrel, on the supposition that four barrels of beer were drawn from every quarter mashed. The old duty was 2d. per ℔ and 5 per cent. additional. A hop-garden costs from £70 to £100 to start, and from £27 to £30 to farm per annum. A rich, deep soil, rather inclined to moisture, is, on the whole, the best adapted for the crop; but any soil (stiff clay only excepted) will suit, when properly prepared. It should be enriched with the kind of manure best suited to the land the hops are to be grown on; stable and cowhouse dung, old rags, shoddy, guano, sprats, and other decomposed matter are used freely; while on some land peat and lime are required. The land is first rendered fine and mellow by being ploughed and harrowed several times; then, in the spring, a large hole is made and filled with rich mellow earth; into this "sets" or small pieces of the roots of the kind of hop intended to be grown are planted with the buds uppermost and the earth pressed close about them. These sets take three years to come to perfection. Two or three sets to a pole, three poles to a hill, 1050 hills to an acre, is the usual calculation. The hills should be 6 or 8 feet apart, the latter being best on rich land, as there the bine runs the most. The poles are from 12 to 18 feet high, according to the adaptability of the ground for vigorous growth, with the ends that go into the earth charred to preserve them. In America the hop is trained on wires; this has also been introduced into England,—Mr Farmer, of Worcester, having taken out a patent. It is very successful, but the first cost, £75 per acre, has prevented its being used extensively. The hop crop is a most precarious one, and may be said to vary from nothing up to a ton or even 25 cwt. per acre, and in price from £3 to £25 per cwt. In proof of this, at the annual Worcester Fair in 1874, only 74 pockets were on sale, whereas the year before 1000 pockets were in the market, and 2000 more were offered for sale by sample.

The plant is very dependent on the season, and has many enemies in the insect world, in particular, the fly or aphis, which infests the crop early in its growth, feeding upon its juices and leaves, giving the latter the appearance of having been riddled with swan shot. The flies come originally from the sloe bushes, and are produced from eggs deposited in the previous autumn. These, as well as fleas, red spiders, lice, &c., may be destroyed by syringing the plants well with soft soap and water. The mould first betrays itself in yellow and drooping leaves, finally in the hop itself, eating it up with mildew,—the presence of a few half-eaten leaves spoiling a sample. The blight coats the leaves with a thick sooty substance; and when this appears the hop dwindles away. The fire-blast, as its name implies, sears and scorches the foliage, and withers it up. All these may be seen working mischief at once in the same hop garden.

The catkins of the hop ripen early in September; they are picked from the bine by thousands of people from London, &c., whose welfare and accommodation have been much neglected; but great changes in this respect are made by sanitary regulations which come into force this season (1875). Besides these strangers, every man, woman, and child of the resident population is made available for the season, which generally lasts three weeks. The pay is about 2d. per bushel; and in a good season a family can make 2s. 6d. a day per head.

After picking, the hops are dried on a kiln (oast-house, as its called),—the heat never being allowed to rise above 90°, lest the aroma and volatile oil should be thrown off. A small portion of sulphur is sometimes added to the fire, the appearance of the sample being improved by the sulphurous acid thus formed. This has been generally considered by brewers injurious to the hop, and also to fermentation; but a commission appointed by the Bavarian Government in 1855 (the late Professor Liebig being one of its members), after two years of experiments, arrived at

the conclusion that the use of sulphur was beneficial to the hop, and not injurious to fermentation. It is frequently used while the plant is growing to cure the various diseases to which the hop, like the vine, is liable. The last process before the hops are brought to market is "bagging." This used to be done by "footing," that is, letting the empty bag drop through a hole in the floor, and having the hops stamped down by one man, whilst two others filled; after which they were pressed by hydraulic power. Under a new process the whole operation is effected by machinery in about eight minutes. Hop-growers, as a rule, have no stores or convenience for warehousing hops for more than a month or two; the consequence is the whole growth, whether large or small, gets into the hands of a few great hop merchants, who command the market.

The best hops have a yellow, golden colour, and an agreeable smell; when rubbed between the hands they leave a yellow, odoriferous, sticky powder on them, without any broken parts of the leaves, and yield to boiling alcohol from 12 to 15 per cent. of soluble yellow matter. A very pale green colour indicates that the hops have been gathered before they are fit; whilst a deep brown shade would show they were allowed to hang too long before being gathered, or that they have been over dried on the oast-house floor. A fair test in choosing hops for India pale ale is to make a strong decoction of them with boiling water, putting it into a white bottle, corked and exposed to the sun; if in twenty-four hours the colour has become dark they are not fit for the purpose.

During the year 1852 only 34,622 ℔ of foreign hops were imported; in 1853 this increased to 4,739,307 ℔, and in 1871 to 24,685,808. Before the hop-duty was taken off there was a great deal of betting on the crop, which was computed as equal to so much duty; and the appearance in the Borough of a hop leaf covered with fly from one of the most favoured districts used to cause much consternation. Since the repeal of the duty brewers have been allowed to use any bitter instead of hop, provided such bitter does not give a factitious strength to beer, and thus become a substitute for malt. Many preparations are, in consequence, offered for sale as partial substitutes for hops; but in these none of the noxious, forbidden articles, such as *Cocculus indicus*, &c., &c., are found, for we learn from the laboratory returns of the Inland Revenue that, in the year 1872, only six samples of beer tested were found to be adulterated. Considering the enormous extent of our brewing industry (it is calculated that 900,000,000 gallons of beer are brewed annually), such testimony to the purity of the beer is highly creditable to those engaged in the trade. From the same source, we learn that in every instance where an adulterant of a dangerous nature was used, the offending parties have been those who brewed and retailed their own beer on a very small scale.

Age alters and deteriorates the character of hops in a marked and distinct degree, much more so than in most aromatic substances; indeed, it changes them to such an extent that, at the end of two years (when they are called "old olds"), they retain little but the bitter, the aroma being gone.

In the year ending 30th September 1874, the hops imported into Great Britain were—

	Cwt.
From Belgium	60,338
„ Germany	39,459
„ Holland	16,035
„ United States	2,809
„ Other countries	4,875
	123,516

being a decrease on 1873 of 11,626 cwt.

Hops are grown with success in Tasmania, upwards of 450 acres being under cultivation. The Australian market, it is supposed, will be eventually supplied from thence. At present between 600 and 700 tons of hops are exported from England yearly.

Water.—Pure water, protoxide of hydrogen, is obtainable only by art; it is therefore impossible, even were it desirable, to use that in brewing. But good water is an indispensable element in the manufacture of good beer. It should be hard and free from organic matter; this last point cannot be urged too strongly, as this alone frequently causes failure in brewing operations. From Cohn's investigations we find that the germs of putrefaction are so small that no filter of charcoal or other material removes them. It is also doubtful if ordinary boiling destroys these organisms. Pasteur asserts they are not killed below a temperature of 100° C. (=212° Fahr.); and Lex found them alive after heating to 260° Fahr. Water charged with them is a decided loss to the brewer, as the organic matter is decomposed during brewing and carries off some portion of the strength of the worts, besides making the beer liable to spoil. Soft water, or water that has flowed through moorland, and is free from saline matter, is bad for the brewer's purpose. When this has to be used for want of a better it should be impregnated at second hand with chloride of sodium (common salt) and gypsum (sulphate of lime). To allow for the deficiency of salt in some water the Excise allow brewers to add sufficient salt to make up, with that naturally in the water, 50 grains per imperial gallon. Soft water gives greater extracts, as it dissolves the albuminous matter in the malt more effectually than hard. With the use of very soft water as much as 100 ℔ of extract per quarter has been obtained; but here the goodness of the extract was the chief proof of the badness of the water; for it is dangerous to have too much albuminous matter in solution, except in the case of porter or ale that is quickly consumed, albuminous bodies being such powerful agents of change. Hence the Burton brewers, whose beers have to stand a long time, and in all climates, are perfectly right in praising their water, which contains a large proportion of these mineral salts. The supposed superiority of the Burton ales is due to the water, which is supplied, not from the River Trent, but from wells 20 to 120 feet deep. These wells are supplied from springs rising in the Outwood hills that form the western side of the valley. The springs take up lime in their passage through the gypseous deposits contained in the keuper marls of the district. The presence of sulphates and carbonates of lime and the absence of organic matter make the water of that district so advantageous for brewing. The following is an analysis of the water used in one of the largest breweries in Burton, showing the amount of ingredients in the imperial gallon, represented in grains:—

Chloride of Sodium	10·12
Sulphate of Potash	7·65
„ Lime	18·96
„ Magnesia	9·95
Carbonate of Lime	15·51
„ Magnesia	1·70
„ Iron	0·60
Silicic acid	0·79
	65·28

The water of another large firm in the same town gives by analysis 54·5 grains of sulphate, and 9·93 of carbonate of lime. The temperature of water used to be a great consideration for refrigerating the worts; but this is now of little consequence, as in most large breweries the water used for that purpose is first brought to a point just above freezing, by means of ether spray.

We now come to the actual process of brewing, or the

art of making the materials we have described into beer. While brewing cannot be considered a difficult or a mysterious art,—good materials, a good method, and strict attention being the secrets of success—there is no process in which rules are of less avail. To obtain complete success, it is necessary that the brewer shall have formed an opinion of his materials from personal observation, and that he should be thoroughly acquainted with the brewery in which they are to be used. It is not too much to say, that the same heats and quantities cannot properly be used in any two breweries. Bearing this difficulty in mind, we shall endeavour to point out where instructions may be safely followed, and where the circumstances of locality, &c., will subject them to certain modifications which cannot be strictly defined in an article like the present.

Brewing consists of eight distinct processes, which may be classed as follows:—

1. Grinding.	5. Cooling.
2. Mashing.	6. Fermenting.
3. Sparging.	7. Cleansing.
4. Boiling.	8. Racking and storing.

Grinding.—This is a very important operation; for, if imperfectly performed, some of the "goodness," or "extract" as it is called, will be left in the grains after mashing, thus entailing a heavy pecuniary loss on the brewer. The malt is crushed rather than ground between plain metal rollers; this is enforced by law, for the purpose of facilitating the examination of the grain as to whether it has been malted or not. Previous to the passing of the Act fraudulent brewers mixed raw grain with their malt, grinding it all up fine, to prevent identification. Each corn should be well broken, that the mashing water may have free access to every particle; on the other hand, if the malt be ground too fine, it is liable to "set," that is, form a paste in the mash tun. When this happens it will be difficult to draw the wort off, and when off it will contain so much of the coarser portion of the grain that the flavour and keeping qualities of the beer will be impaired. If possible the crushed malt should stand about twenty-four hours before being mashed, care being taken to protect it from air or damp,—the object being to allow the heat generated by passing through the rollers to escape.

Mashing is the process of infusion, or mixing the malt with water at such a temperature as shall not only extract the saccharine matter existing in the malt, but shall also change the still unconverted starch into grape-sugar. This is accomplished by the principle called diastase, the power of which we have shown under the head of malting. Many mashing-machines have been invented, and many are in use. In some the malt and the water are simply brought into conjunction, and then mix themselves as they fall into the mash-tun; others, driven by steam, perform the operation of mixing more leisurely, and, in some cases, more effectually. The old-fashioned method of mashing is by means of iron rakes. These rakes are fixed on arms extending from the centre of the tun, and are so constructed that when set in motion, no portion of the mash escapes them. When rakes are used a portion of the mashing water is first run into the tun, and part of the malt; the machinery is then started, and, whilst the rakes revolve round the tun, the remainder of the malt and water are added. The heat of the mashing water is a very important point; the particular temperature must depend upon the quantity and quality of the malt, and the situation of and amount of radiation from the mash-tun. Not less than two or more than three barrels of water should be run on to every quarter of malt, and the heat of the water should be such, that, when all has run on, that is, when the malt has combined with the water, the temperature of the mash shall not be lower than 148° or higher than 152°. In some breweries this result will be obtained by mashing at 168°; in others it will be necessary to go as high as 180°. Neither of these heats will do any harm so long as the heat of the mash does not exceed 152°. Most brewers and chemists think that, to ensure the best results, it is necessary for the mash to stand at least two hours. It would appear, however, that this belief has no solid foundation. Recent observations have convinced the present writer that an extract as good, and perhaps sounder, is drawn from a five minutes' mash as from one that has stood two hours,—a fact which any brewer can test for himself. The wort should be drawn off by means of several pipes running from different parts of the mash-tun. It must be run off slowly at first, or the malt in the tun ("goods," as it is now called) will be drawn down so tightly that it will be difficult for the sparging water to run through it. It is a good plan to probe the mash now and then with a thin stick; if the "goods" feel tight, and difficult to penetrate, the wort is being run off too quickly.

Sparging.—When about half the wort has run off the mash, the operation of sparging should be commenced,—the object of that process being to wash out the goodness left in the malt after mashing. The sparging-machine is made and fixed as follows:—A bar of iron having an upright pin in the centre is fixed across the mash-tun; on this pin is placed a copper bowl or pan; into this pan are screwed two or three arms, extending to the sides of the tun. These arms are about an inch and a half in diameter, and are perforated their whole length with small holes on their reverse side. The hot water being conveyed into the pan fills the arms, and, running out through the perforated holes, causes the arms to revolve round the tun. By this means an equal and continuous shower of hot water is rained upon every portion of the goods. The heat of the sparging water, like that of the mashing liquor, must be modified by circumstances. In brews of less than 10 quarters, 200° will be found to be a good heat; where larger quantities are mashed 185° may be recommended as a safe temperature.

Boiling.—When the wort runs off the mash no time should be lost in getting it into the copper or boiling back. In many modern breweries the mash-tun is placed immediately over the copper, so that the wort runs direct from the former utensil into the latter. Some coppers are built with an ordinary furnace, others are furnished with a coil; in the latter case the worts are boiled by steam passing through the coil from the boiler. Many brewers prefer to boil by steam, as it is a cleaner method, and they are able to regulate the operation to a nicety. Where the steam coil is used the boiling back is generally made of wood. While the wort is running or being pumped into the copper, the hops must be added. Here, again, no positive instructions as to quantity can be given. On this point the brewer must be guided by his customers' tastes, the season of the year, the length of time the beer has to be kept, and the quality of the hop used. For strong store ales, from 10 ℔ to 13 ℔ of good hops to every quarter of malt is not too much; whilst for ordinary beers, to be drunk within two months, from 6 ℔ to 9 ℔ per quarter should suffice. India pale ale and bitter beer require from 18 ℔ to 25 ℔ per quarter. Various kinds of English and foreign hops can be used in the same brewing with advantage; the proportions of each kind must be left to the judgment of the operator. Of course, the ranker Bavarian and American hops must not be so freely used as the more delicate English growths. There is a wide difference of opinion as to the length of time beer should be boiled. For beers of quick draught, an hour and a half

is long enough; stock ales should have half an hour or an hour extra. The finest pale ale is never boiled longer than one hour. Where it is necessary to have two boilings in one brewing, the second copper should boil rather longer than the first. The boiling during the first twenty minutes should be brisk, in order to break the wort.
